A sulphate of lead was found in considerable quantities mixed with the soil or earth which immediately reposed upon the copper ore. The lead obtained from this sulphate contained from fifty to sixty ounces of silver in each ton, and a great quantity of the sulphate was dug, in the expectation that it would be profitable to smelt it, and afterwards extract the silver. This expectation, however, though apparently well grounded, was never realized; for in separating the sulphate of lead from the soil, and also in the process of smelting, difficulties occurred, which it was found impossible to overcome in practice.

It is exceedingly probable that the Parys mountain, or its immediate neighbourhood, was formerly the scene, if not of successful enterprise in mining and smelting, at least of trial and experiment. Long before the present mines were discovered, a collection of waters upon the summit of the mountain was known by the name of the Mine Pool; and a hearth for smelting lead, some pieces of lead and charcoal, and a plate of copper weighing about 50lbs., all found anterior to the opening of the modern mines, seem to attest that the minerals in the vicinity of Amlwch attracted the notice of a generation remote from our own.

AMMIANUS MARCELLINUS, a soldier and author who lived in the fourth century, and wrote a history of the emperors from the accession of Nerva, A.D. 96, to the death of Valens in 378; the last profane history written by a Roman subject in the Latin language. He was of Greek family, and born at Antioch; at least Libanius claims him as a fellow-citizen. At an early age he entered the army, in the distinguished service of the household guards of Constantius, son of Constantine. He was peculiarly attached to the fortunes of Ursicinus, the master of the horse, under whom he served, first in the East in 350, afterwards in Gaul, whither he went in 355. He was again sent with Ursicinus into the East, and served under the Emperor Julian in his Persian war, which he related at length and with considerable power. Later in life he retired to Rome,

where he wrote his history, in thirty-one books. Of these, the first thirteen are lost, the least valuable part, since they can but have contained an epitome of the history of two centuries and a half. The fourteenth book begins just before the death of Constantius, and the transactions of the reign of Julian extend nearly to the end of the twenty-fifth. The question whether he was a Christian or a pagan has been agitated. Though he has not expressly stated his sentiments, it seems evident to us that at least he was not a Christian. In style he is inflated and vicious; but passages of considerable effect and eloquence occur in his work, which has every appearance of being a faithful and unprejudiced narration of public transactions, in many of which he had been personally engaged. "It is not without sincere regret," says Gibbon, "that I must now take leave of an accurate and faithful guide, who has composed the history of his own times, without indulging the prejudices and passions which usually affect the mind of a contemporary." Chap. xxvi. Some suppose the Greek life of Thucydides to be written by him. The early editions of Ammianus are numerous. The most valuable is that of Gronovius, folio, Lugd. Bat., 1693; which contains the life and prefatory matter of the Valesii. This has been the base of two other editions, with the notes of later commentators, both published at Leipzig, (Lips.) one by Ernesti in 1773, one by Erfurdt in 1808. There is an old English translation by Philemon Holland, (Lond. 1609,) and a French one by Moulaines, (Berlin, 1775, Lyons, 1778.)

AMMON, or AMUN, or AMN RA, the name of an Egyptian deity, whom the Greeks considered as synonymous with their Zeus (Jupiter). He is often represented on the monuments of Egypt and in other works of Egyptian art with a ram's head and a human body; about which Herodotus (ii., 42) tells the following odd story, picked up during his travels in Egypt:—"Hercules was exceedingly anxious to have a sight of Zeus, but Zeus did not feel inclined to show himself. At last, when Hercules was very importunate, Zeus hit on the following contrivance: he flayed a ram, and cutting off the head put it before his face; he then got into the skin, and in this guise showed himself to Hercules. From this circumstance the Egyptians represent the image of Zeus with a ram's head. But the ram's head is not the peculiar property of Ammon: it is found also, for instance, on the head of Cneph, with the appropriate distinguishing symbols. We consider the community of symbols in the representations of different deities, as indicating the origin of the political union of the several tribes or peoples to whom the several deities belonged.

The worship of Ammon was not, like that of Osiris and Isis, common to all the Egyptians: it seems to have been specially of Ethiopian origin. The two chief Ammonian temples which now exist are that at Carnak, on the east side of the Nile, forming part of the extensive ruins of Thebes, and that of Siwah, in the Libyan desert, known to the Greeks by the name of Ammonium.

The god Ammon appears also under the figure of a crio-sphinx or ram-sphinx, which is an animal with a ram's head and the body of a beast of prey of the feline species. (See *British Museum*:—*Egyptian Antiquities*, vol. i., and the drawings in the French work on *Egypt. Antiquités*, tom. iii., pl. 32.)

The word Ammon cannot, we think, be satisfactorily explained from the Coptic language, as it now exists. The various guesses and conjectures may be seen in Jablonski's *Pantheon*, vol. i.; out of all the guesses, that which connects the word *Ammon*, or *Amun*, with the Coptic word signifying 'to feed' sheep, is the most probable. (See *Coptic Testament*, John xxi. 15; &c.) Ammon then would be the god of a Nomadic race, and originally a pastoral deity.

We find the *city* or *portion* of Ammon mentioned in Jeremiah xli. 25; Ezekiel xxx. 15., under the name of Amon-No; and in Nahum iii. 8., under the name of No-Amon. This city is generally supposed to be the Greek Diospolis, or 'city of Jupiter,' now forming part of the ruins of Thebes. But the No of Nahum is more probably the Diospolis of the Delta.

The name Amon forms a part of the proper name of several Egyptian kings and persons, such as Amenoph (see MAMNON), and Ptamon; and is also often used in the title or qualifying term applied to the name of a king: thus we find on the monuments prefixed to the name of Rameses, the title *Amm-mai*, 'beloved by Ammon.' This may be compared with such Greek proper names as *Diphalus*,

'dear to Jupiter,' and such German names as *Gottlieb*, (Theophilus) 'dear to God,' *Gottfried* (Godfrey) 'peace of God.'

AMMONIA, the modern name of the *volatile alkali* formerly so called to distinguish it from the more fixed alkalis: it is a gaseous body, and was first procured in that state by Priestley, who termed it alkaline air. (*Experiments on Air*, vol. ii. p. 370.) He obtained it from sal ammoniac, and hence the present name of the alkali.

Ammonia, like all the other alkalis, is a compound substance; it consists of azote and hydrogen, in proportions hereafter to be mentioned; it exists, combined with various acids, in urine and in some calculi. M. Boussingault (*An. de Chim. et de Phys.*, xliii., p. 334.) found it in a native oxide of iron, and Dr. Marcet (*Phil. Trans.* 1823) detected it in sea water combined with muriatic acid. Ammonia cannot be formed by direct action after its elements have both assumed the gaseous form; it is requisite that one of them should be in the nascent state: it is generated during certain natural processes, and is obtained by several artificial ones; these will be noticed after a description of the method of preparation first employed by Dr. Priestley, and still adopted by chemists, has been given.

Sal ammoniac, a salt already mentioned, is a compound of muriatic acid and ammonia; when it is powdered and mixed with three-fourths of its weight of powdered lime, and heated in a retort, ammoniacal gas is plentifully given out, which must be received in jars filled with and inverted in mercury. The changes which occur during the production of the ammonia are of a complicated nature. Sal ammoniac, or muriate of ammonia, consists of muriatic acid and ammonia, and the acid itself is constituted of chlorine and hydrogen; lime is composed of the metal calcium and oxygen. When the muriate of ammonia and lime act upon each other, the chlorine of the muriatic acid combines with the calcium of the lime, and the resulting chloride of calcium remains in the retort, while the hydrogen of the acid combines with the oxygen of the lime to form water, which evaporates with the ammonia evolved.

The ammonia thus obtained is æriform; and as it does not become fluid under common circumstances of temperature and pressure, nor solid in any case, is termed a *gas-ammoniacal gas*. Its properties are, that it is colourless, transparent, and of course invisible; possessing the elasticity and mechanical properties of atmospheric air. The smell is peculiar and extremely pungent, and its taste is highly acrid. An animal put into it is immediately killed, and a taper when immersed in it is extinguished: it appears, however, to be slightly inflammable, for the flame is rather enlarged before it goes out; and a small jet of the gas may be burned in oxygen gas. The density of ammoniacal gas is to that of atmospheric air, nearly as 0.5902 to 1; 100 cubic inches weigh rather more than 19 grains. It acts strongly as an alkali, turning vegetable blues green, and yellows reddish brown, and saturates acids forming various salts.

Mr. Faraday (*Phil. Trans.* 1823, p. 189) found, that by subjecting ammoniacal gas to a pressure of about 6½ atmospheres, at the temperature of 50°, it became a colourless transparent fluid, the density of which was 0.760, water being 1.

Water dissolves ammoniacal gas with great rapidity, and in large quantity; a few drops of water thrown up into a jar of the gas instantly condense it; a piece of ice also immediately liquefies in and condenses the gas. Water at 50° is capable of condensing 670 times its volume; the density of the solution diminishes as its strength increases, so that, according to Davy, with whom other chemists nearly agree, when water contains 9½ per cent. of ammonia, its density is 0.9692; but when it holds 32½ per cent., it is reduced to 0.8750. The aqueous solution is colourless, transparent, and has the pungency and alkaline property of the gas: by exposure to the air, the ammonia escapes, and by the application of heat it is expelled from the water; on account of this volatility of ammonia, vegetable colours which have been altered by it regain their original tints as it evaporates, which is not the case when the change has been caused by the fixed alkalis.

The presence of ammonia may be detected by its strong smell, by holding moistened turmeric paper where it is suspected to exist, and by the formation of a white vapour, when exposed to a glass rod moistened with muriatic acid.

Dr. Priestley found that the strong light of a lens produced

no effect upon ammoniacal gas. By moderate degrees of heat it is merely expanded, but when passed through an ignited porcelain tube, as was first shown by Dr. Priestley, it is decomposed, and, increasing to nearly double its volume, rendered inflammable. (*Experiments on Air*, vol. ii., p. 393.) He also first proved that it is decomposed by the electric spark, and separated into hydrogen and azotic gases, (vol. iii., p. 389.) These experiments have been repeated by Berthollet, Davy, and Gay-Lussac. Dr. Henry (*Annals of Philosophy*, N. S., viii., p. 347) also found that when ammoniacal gas is electrified, its volume is exactly doubled, and it is resolved into three volumes of hydrogen gas, and one volume of azotic gas. As the result of these experiments, it is now generally admitted, that ammoniacal gas is a compound of three volumes of hydrogen gas and one volume of azotic gas, condensed into two volumes: by weight it is composed of

Three atoms of hydrogen	$1 \times 3 = 3$	or hydrogen	17.64
One atom of azote		= 14	azote . . . 82.36

Weight of its atom	= 17	100
--------------------	------	-----

That this is the composition of the gas in question is also shown by comparing its calculated and actual density. According to Dr. Thomson (*Chemistry of Inorganic Bodies*, vol. i., p. 704) 300 cubic inches of hydrogen gas weigh 6.1842 grains, and 100 cubic inches of azotic gas weigh 30.2794 grains, making together 36.7636; but during combination the gases condense to half their volume, consequently 200 cubic inches of ammoniacal gas weigh theoretically 36.7636 grains, and 100 weigh 18.3818. Now according to Allen and Pepys the weight by actual experiment is 18.18 grains, which is sufficiently near the calculated statement to prove its correctness.

Ammonia is used for many purposes both in medicine and in scientific chemistry; as however it would be impossible in some cases, and inconvenient in almost every one, to employ it in its gaseous state, it is used in solution in water, and then frequently called *liquid ammonia*: but this term can be applied with propriety only to the gas rendered fluid by cold and pressure. Solution of ammonia may be readily prepared by mixing muriate of ammonia with lime, in the mode and proportions already mentioned, and passing the gas liberated into water: this may be done either by inserting a glass tube bent at right angles into the mouth of the retort, and then putting the other end into a bottle of water; or, which is better, in case absorption should take place, a tubulated receiver may be used instead of the bent tube, securing it properly by a perforated cork to the retort, and luting it so that it may withstand the pressure of passing the gas into the water.

Having now stated the direct method of preparing ammoniacal gas, its properties, composition, and aqueous solution, it will be proper to notice the different processes, both natural and artificial, by which it is produced in large quantity. The first of these is the putrefaction of animal matter. We have already mentioned that hydrogen and azote are the elements of ammonia, and, with some exceptions, there is this difference between animal and vegetable matter, that the first contains azote, while the latter does not. When, then, animal matter is subjected to decomposition, whether the operation be the natural one of putrefaction, or the artificial one of the application of heat, ammonia is one of the results obtained by the new arrangement of its elements, and it is combined with carbonic acid, forming carbonate of ammonia. It will be readily understood how this happens: the animal matter consisting of hydrogen, azote, oxygen, and carbon, the first two gases unite to form ammonia, and the two latter elements to constitute carbonic acid; it is extremely probable, also, that during putrefaction the oxygen of the atmosphere may assist in the formation of this acid.

Ammonia may be artificially produced from most animal matter, except fat, by subjecting it to heat in iron cylinders; and when bones, hoofs, or horns, are thus decomposed, a large quantity of carbonate of ammonia is obtained, some of which is in a solid form, but the greater portion is dissolved in water and mixed with empyreumatic oil. This liquor has a dark colour, and a pungent, disagreeable smell: when it is purified so as to separate the greater part of the oil, it is the *spirit of hartshorn* of the shops. The hard portion of bone, being mostly phosphate of lime, does not yield any ammonia, but there is intermixed with it a large quantity of a substance termed chemically *gelatine*, which is similar to is-

glass, and that this yields ammonia is readily shown by heating it in a retort with a spirit lamp; the product received in a vessel containing turmeric paper soon renders its yellow colour reddish-brown; and there are also produced water, carbonic acid, and empyreumatic oil.

Vegetable matter, when azote is one of its elements, as the gluten of wheat, yields ammonia if heated: coal soot also contains it; but the decomposition of coal, effected during the production of carburetted hydrogen for the purpose of gas illumination, is now an abundant source of ammonia, which, by various processes, is converted into sulphate, muriate, or carbonate.

It has been already observed, that although hydrogen and azote constitute ammonia, yet when they have both assumed the gaseous state they cannot be made to unite. Dr. Austen (*Phil. Trans.*, vol. lxxviii. p. 380) attempted to combine them by electricity, cold, and other methods, but he did not succeed; he found, however, that when iron filings moistened with water were exposed either to azotic gas or atmospheric air, the nascent hydrogen of the decomposed water united with the azotic gas and formed the alkali in question, and it occurred most readily in the pure azotic gas.

Ammonia may also be produced by the action of both elements in their nascent state; if tin filings be put into nitric acid diluted with water, rapid action ensues, with the evolution of much nitric oxide gas, and the formation of peroxide of tin. In this process, a portion both of the nitric acid and water is decomposed, azote from the former, and hydrogen from the latter, both in their nascent state, combine, and the resulting ammonia forming nitrate with the undecomposed nitric acid, this salt is diffused through the peroxide of tin; add lime to this mixture, and owing to its greater affinity for nitric acid than of ammonia for it, nitrate of lime is produced and ammoniacal gas evolved, as may be ascertained by the smell and its action upon turmeric paper. Iron and phosphorus decompose diluted nitric acid with similar results; and it has also been found, that the rust or peroxide of iron formed within houses is capable of absorbing and strongly retaining the ammoniacal vapours there developed. (*Ann. de Chim. et de Phys.* 24—99.)

In the *Quarterly Journal of Science*, &c. (vol. xix. p. 116.) Mr. Faraday has detailed some very curious cases of the production of ammonia, in which the substances yielding it are, according to the present state of chemical science, destitute of the azote supposed to be necessary to its formation. From among numerous experiments, the following may be selected as one of the most striking:—a glass tube was filled with hydrogen gas, a piece of zinc foil dropped into it, and upon that a portion of hydrate of potash, and a slip of moistened turmeric paper was then introduced. The potash was melted by a spirit-lamp and suffered to run upon the zinc, and by continuing the heat, the turmeric paper was reddened owing to the evolution of ammonia. Now the elements included in this operation were oxygen, hydrogen, zinc, and potassium; the source, therefore, of the ammonia is by no means evident, and it is difficult of explanation.

The hydrates of soda, lime, and barytes produce similar effects; and much ammonia may be evolved by their action upon iron, tin, zinc, lead, and arsenic. But spongy platinum, silver, and gold do not produce any; the metals, therefore, seem to act according to their power of absorbing oxygen; and water or its elements appear to be necessary to the experiment.

We shall now briefly notice the nature and results of the action of ammonia upon certain elementary bodies. It has been already stated that ammoniacal gas may be burned in oxygen gas; a mixture of these gases may also be fired by the electric spark, the results being water and azotic gas; a little nitric acid is also generated, if the quantity of oxygen gas be sufficient to combine with all the hydrogen of the ammonia. (Dr. Henry, *Phil. Trans.*, 1809.) Chlorine gas, by mere admixture with ammonia, decomposes it partially, and the action is attended with the evolution of light and heat: the chlorine combines with a portion of the hydrogen of the ammonia; muriatic acid is thus formed, which uniting with the ammonia remaining undecomposed, the result is muriate of ammonia, while azotic gas is liberated. The same effects are obtained, if the aqueous solutions of the gases in question be employed; but then the changes are unaccompanied by light or heat.

Ammonia has no action upon carbon, except at a high

temperature; if, however, a piece of well-dried charcoal be passed up into ammoniacal gas over mercury, it is capable of absorbing ninety times its volume in twenty-four hours. The gas undergoes no chemical change, and from Saussure's experiments, it appears that the absorption is analogous to the capillary attraction of liquids by very small tubes. Sulphur, when strongly heated in ammoniacal gas, partially decomposes it, and hydrosulphuret of ammonia is one of the products. At a high temperature, phosphorus also decomposes ammonia and phosphuretted hydrogen is formed; when no heat is employed, phosphorus absorbs the gas, and a deep-brown coloured substance is formed which is almost pulverulent: its properties have not been examined. Iodine and ammonia, provided both be perfectly dry, combine without the agency of heat, and form iodide of ammonia. (Colin, *Ann. de Chim.* xci. p. 262.) The compound is formed immediately on mixture: it is a shining viscid liquid, of a brownish-black colour, but as the absorption of ammonia goes on, it loses its lustre and viscosity. It is not fulminating, but, if put in contact with water, the ammonia is decomposed, and a black powder formed, which is the well-known detonating substance *iodide of azote*, generally prepared by putting iodine into the aqueous solution of ammonia.

The action of the metals upon ammonia varies considerably according to their nature. Gay-Lussac and Thénard have shown that potassium and sodium absorb ammoniacal gas, and are covered with a white crust. The absorption is more rapid when the heat of a spirit-lamp is employed; the white crust becomes deep yellow, the surface of the metal is brilliant and smooth, whilst the new compound is greenish, fuses, and runs upon the sides of the tube; when the operation is continued until the potassium entirely disappears, ammoniacal gas is not only absorbed, but a portion is decomposed and hydrogen gas given out. The compound formed is of a deep olive-green colour, its fracture crystalline, and its density greater than that of water. It fuses at a temperature higher than boiling water, does not conduct electricity, burns in oxygen gas, and yields hydrate of potash and azotic gas. Water decomposes it rapidly; the results are potash and ammoniacal gas. Gay-Lussac and Thénard consider it as a compound of azoturet of potassium with ammonia.

When ammoniacal gas is passed over ignited iron or copper, the density of the metals is much diminished; and by the repeated action and decomposition of the gas, iron may be increased in weight, as proved by Despretz, 11.5 per cent., which increase is owing to the absorption of azote by the metal. It has been mentioned under the head of amalgams, that mercury and ammonia, when subjected to the action of voltaic electricity, form a compound which has been termed an amalgam. This experiment was first made by Berzelius and Pontin, and may be thus performed:—put some mercury into an open glass capsule, and place in it a platina wire connected with the negative pole of the battery; pour on the mercury a strong aqueous solution of ammonia, and connect this by a platina wire, at the distance of a line from the mercury, with the positive pole of the battery. When the battery is rendered active, the positive extremity first gives out gas, but soon after it is disengaged also from the mercury, which expands, becomes gradually as thick as butter, is of a silvery-white colour, and eventually increases to five or six times its original volume.

At a temperature of 70° to 80° of Fahrenheit, the amalgam is a soft solid; at 32°, it is a firm crystalline mass. Its density is about 3, water being 1. If exposed to the air it soon becomes covered with a white crust of carbonate of ammonia; and when thrown into water, the mercury returns to its original state, a weak solution of ammonia is formed, and hydrogen gas is evolved equal to half the volume of the amalgam used in the experiment.

Davy improved this process by putting about 50 grains of mercury into a cavity made in a piece of moistened sal-ammoniac, placed on a platina plate attached to the positive pole of the battery, while the mercury was connected by a platina wire with the negative one. This process is not only more easily executed than the foregoing, but the amalgam obtained by it is more permanent.

Great difference of opinion prevails as to the nature of this amalgam. Gay-Lussac and Thénard consider it as a mere combination of mercury and ammonia, while Berzelius regards it as a real amalgam of mercury and *ammonium*, which he considers as a metal, composed of one volume of azotic gas, and four volumes of hydrogen gas; this opinion

is, however, entirely hypothetical, and is shown by numerous facts and analogies to be extremely improbable.

Although mercury is the only metal which appears to combine with ammonia, there are several metallic oxides which unite with it. These compounds are called *ammoniuirets*, and will be described under each metal: for the present we shall merely mention, that the solution of ammoniuiret of zinc is colourless; that of peroxide of copper is purple, and of nickel the same, except when the excess of ammonia is driven off, and then it is green, the ammoniuiret of cobalt is of a fine red colour. The solid ammoniuirets of silver and gold are extremely explosive substances, and are called fulminating gold and silver. With the various acids, ammonia forms salts: we shall, however, describe only the more important, viz., the acetate, carbonates, muriate, nitrate, oxalate, and sulphate.

Acetate of Ammonia.—This salt is prepared by adding sesquicarbonate of ammonia to dilute acetic acid. Owing to the superior affinity of the acetic acid for the ammonia, the carbonic acid is expelled from it with effervescence, and a colourless solution remains, which, when concentrated, and placed under the exhausted receiver of an air-pump, over sulphuric acid, yields transparent prismatic crystals, the taste of which is hot; they are very deliquescent. According to Dr. Thomson, they are composed of 1 atom of acetic acid, 51; 1 atom of ammonia, 17; and 7 atoms of water, 63; their atomic weight is, therefore, 131.

Acetate of ammonia is directed to be prepared in the *London Pharmacopœia*, and kept in solution under the name of *Liquor Ammoniac Acetatis*. It is used externally as a refrigerant, and internally as a diaphoretic, and is commonly known by the name of *Spirit of Mindererus*.

Carbonates of Ammonia.—Of these there are three, the *carbonate*, *sesquicarbonate*, and *bicarbonate*. The carbonate may be procured by mixing one volume of carbonic acid gas and two volumes of ammoniacal gas in a jar over mercury; they immediately condense into a white solid, which is carbonate of ammonia. It may be also prepared by mixing and heating carbonate of potash and muriate of ammonia. By a series of decompositions, the carbonic acid is transferred from the potash to the ammonia of the muriate, and the carbonate formed, being volatile, rises in vapour, and is condensed in the upper part of the subliming vessel. It is a white salt, pungent to the smell, and acrid to the taste; soluble in cold water, and decomposed by hot water. It acts as an alkali upon vegetable colours, and consists of

One atom of carbonic acid 22
One atom of ammonia . 17

Atomic weight . . . 39

It is used in medicine as a stimulant in a preparation called in the *Pharmacopœia*, *Spiritus Ammoniac Aromaticus*, and commonly *Spirit of Sal Volatile*.

Sesquicarbonate of Ammonia.—This salt is contained in the *Pharmacopœia* under the incorrect name of *Ammoniac Subcarbonas*, or *subcarbonate of ammonia*. It is directed to be prepared by heating, in a subliming vessel, a mixture of one part of muriate of ammonia, or sal ammoniac, and one part and a half of carbonate of lime or chalk; it is, however, usually, and more economically obtained by decomposing sulphate of ammonia with carbonate of lime. In this case, double decomposition ensues, sesquicarbonate of ammonia is formed, volatilised, and is condensed in the upper part of the vessel, while sulphate of lime remains in the lower.

Sesquicarbonate of ammonia is a colourless, translucent, moderately hard salt; it has a pungent smell, and a sharp, penetrating taste, but less so than the carbonate. It is soluble in about four times its weight of cold water, and is decomposed by hot water. It acts upon vegetable blues and yellows, like an alkali, and on this account, as well as its ammoniacal smell, has been called a subcarbonate.

It is composed of

Three atoms of carbonic acid 66
Two atoms of ammonia . . 34
Two atoms of water . . . 18

Atomic weight . . . 118

As three atoms of carbonic acid are combined with one atom of ammonia, and these being as one and a half to one, this salt, like others similarly constituted, is generally termed a *sesquicarbonate*.

It is used in medicine as a stimulant, and usually called *smelling salts*. It is also employed as a substitute for yeast in making some of the finer kinds of bread. As a chemical re-agent, it is extensively used; and also for preparing various other ammoniacal salts.

Bicarbonate of Ammonia.—This salt may be prepared by mixing, over mercury, equal volumes of carbonic acid and ammoniacal gases, and adding a little water; by passing carbonic acid gas into a solution of sesquicarbonate of ammonia, in which way it may be obtained in crystals; by heating a mixture of equal weights of muriate of ammonia and carbonate of lime in a subliming vessel; or lastly, and with the greatest facility, by exposing powdered sesquicarbonate of ammonia to the air until it becomes inodorous; in this case, a larger proportion of ammonia escapes than remains, and the residue thus becomes a bicarbonate. When obtained by sublimation, it resembles the sesquicarbonate in appearance, but differs from it in being devoid of pungency; it is rather hard, soluble in cold, and decomposed by hot water. When perfect, it has no alkaline action on vegetable colours, like the preceding carbonates. The salt obtained by sublimation, or by exposing the sesquicarbonate to the air, consists of

Two atoms of carbonic acid 54
One atom of ammonia . 17
Two atoms of water . . 18

Atomic weight . . . 89

It is rarely used either in medicine, or as a chemical re-agent.

Muriate of Ammonia.—This salt has been long known, and extensively used, under the name of *Sal Ammoniac*. The substance from which it was first procured, was the soot of camel's dung. It is now largely manufactured in Europe, by combining muriatic acid, either directly or indirectly, with ammonia, obtained from the decomposition of animal matter, but principally from the liquor obtained during the preparation of coal-gas, or carburetted hydrogen. The impure carbonate of ammonia which this liquor contains is either at once saturated with muriatic acid, or first converted into sulphate of ammonia, and afterwards, by decomposing it with common salt, into muriate: the products are sulphate of soda and muriate of ammonia, and this last is separated by crystallization, and sublimed.

Muriate of ammonia, as obtained by sublimation, is an amorphous, translucent, colourless salt; but when separated from water by crystallization, its form is cubic. It has a sharp, saline taste, but no smell, and dissolves readily in water; exposure to a dry air produces no change in it; by heat, it volatilizes without decomposition. Lime and the fixed alkalis decompose it, evolving ammoniacal gas; and sulphuric acid expels the muriatic acid gas. It is composed of equal volumes of muriatic acid gas and ammoniacal gas, as may be shown by the perfect condensation of these proportions in a jar over mercury; or by weight, of

One atom of muriatic acid 37
One atom of ammonia . 17

Atomic weight . . . 54

This salt is much employed in various chemical manufactures. It is generally used for preparing ammoniacal gas, and the sesquicarbonate of ammonia, in the modes already described.

Nitrate of Ammonia.—When sesquicarbonate of ammonia is added to dilute nitric acid, effervescence occurs, owing to the evolution of the carbonic acid of the decomposed ammoniacal salt, and a solution of nitrate of ammonia remains; this, by evaporation, yields slender crystals of nitrate of ammonia; they are colourless, inodorous, very sharply saline to the taste, readily soluble in water, and deliquescent in a moist atmosphere. When heated to about 500° of Fahrenheit, nitrate of ammonia decomposes, and is resolved into water and nitrous oxide gas. Sometimes the solution of nitrate of ammonia, instead of being merely evaporated till crystals are formed, is reduced till the water is so nearly expelled, that the salt solidifies in cooling. In both states it is composed of

One atom of nitric acid 54
One atom of ammonia 17
One atom of water . . 9

Atomic weight . . . 80

It is principally used for preparing nitrous oxide gas.

Oxalate of Ammonia.—This salt is prepared by adding

sesquicarbonate of ammonia to a solution of oxalic acid, until it is saturated. The solution by evaporation yields small prismatic crystals; these are devoid of smell, have a bitter, saline taste, and dissolve readily in water.

Oxalate of ammonia is composed of

One atom of oxalic acid	36
One atom of ammonia	17
Two atoms of water	18

Atomic weight . . . 71

It is used as a test of the presence of lime, and to precipitate it from solution in chemical analyses.

Sulphate of Ammonia.—It has been already mentioned, that this salt is formed as an intermediate step in preparing muriate of ammonia, and this is the principal purpose to which it is applied. In small quantity, it is best made by saturating dilute sulphuric acid with sesquicarbonate of ammonia. The solution is colourless, and by evaporation yields small prismatic crystals; these have a saline taste, and are readily dissolved by water. Crystallized sulphate of ammonia is composed of

One atom of sulphuric acid	40
One atom of ammonia	17
Two atoms of water	18

Atomic weight . . . 75

According to Dr. Thomson there is a variety of this salt, the crystals of which contain only half as much water as the abovementioned; but this kind is not usually met with.

The general properties of the salts of ammonia are as follows: soluble in water, with few exceptions; decomposed by the fixed alkalis, and alkaline earths, with the evolution of ammonia; decomposed when a magnesian salt and a soluble phosphate are added to them, a crystalline precipitate being formed, which is a double salt, composed of phosphate of ammonia and phosphate of magnesia; decomposed and dissipated by heat, except the acid, like the phosphoric and boracic, be a fixed one, in which case the ammonia is expelled, and the acid remains: a solution of muriate of platina occasions a yellow precipitate in solutions of ammoniacal salts.

AMMONIAC (GUM), a concrete juice produced in Persia, Abyssinia, &c., but the plant from which it is obtained does not appear to have been ascertained. Willdenow refers it to the *Heracleum gummi-ferum*, in which he is followed by the British Colleges of Physicians. Others refer it to the *Ferula orientalis*. It consists of grains of various sizes, usually called *tears*: they are either separate or agglutinated into masses; their colour is whitish, but they become yellow by the action of the air; they are shining, opaque, irregular in shape, and more or less globular; when cold, ammoniac is rather hard and brittle, it softens by the heat of the hand, but does not entirely liquefy at a stronger heat. The smell is peculiar and disagreeable, and the taste is nauseous, at first mucilaginous and bitter, and afterwards acrid. Its specific gravity is 1.207. When triturated with water, it is partly dissolved, forming an emulsion which becomes clearer on standing. When distilled with water, it loses its volatile oil, and becomes inodorous; the distilled water has the odour of the gum, and small drops of limpid, colourless oil float on its surface. Alcohol takes up about half its weight, forming a brownish-yellow solution; which becomes turbid when mixed with water. It is combustible, burning with a white flame, little smoke, and a strong smell; the ashes left, consist of small portions of the carbonates of potash and lime, and phosphate of lime.

Sulphuric acid readily dissolves ammoniac, and water precipitates the solution; nitric acid converts it into a bitter substance; the fixed alkalis form with it a turbid solution, which is extremely bitter.

According to Bucholz, ammoniac consists of

Resin	72.0
Gum	22.4
Bassorine	1.6
Volatile oil, water and loss	4.0

100

It is used in medicine as a stimulant and expectorant.

• **AMMONITES**, a nation descended, according to Gen. xix. 38, from the incestuous connexion of Lot with his younger daughter, about the year 1898 B.C. The name of their progenitor, *בן-אמי* *Ben Ammi*, means son of

my kindred, and the name *Ammon* has nearly the same signification. There is no etymological connexion between *בן-אמי* children of Ammon, and the Egyptian word Am-

mon or Amon. The Ammonites, or the children of Ammon, are called by the Septuagint and Josephus, Ammanitæ. The country which they inhabited was situated between the rivers Arnon and Jabbok, N.E. of the Moabites, and east of the tribes of Reuben and Gad. Giants dwelt there, we are told, in old time; and the Ammonites called them Zamzummim (*זמזמים*) those who devise wickedness, a people great and

many, and tall as the Anakim; but the Lord destroyed the Zamzummim before the Ammonites, who dwelt in their land. The Israelites, under Moses, smote the Amorites, and possessed their land from Arnon unto Jabbok, even unto the children of Ammon, about the year 1452 before Christ: but they did not enter the territory of the Ammonites, for the border of the children of Ammon was strong (Num. xxi. 24). The Israelites were directed not to distress the children of Ammon, because the Lord had given the land unto the children of Lot for a possession. About 1161 B.C., the children of Ammon, under their king, passed over the Jordan, and encamped in Gilead with the pretext of recovering the country which they falsely accused the Israelites of having taken from them 300 years before. Jephthah, who then commanded the Israelites, reminded the king of the Ammonites, that the Israelites never went into the borders of Ammon. In the battle that followed, Jephthah smote the Ammonites from Arer to Minnith, and subdued them. (Judges x. xi.) In the year 1095 B.C. Nahash, king of the Ammonites, encamped against Jabesh Gilead, and offered to make terms with the inhabitants on condition that he might put out all their right eyes, and lay it for a reproach upon Israel. Upon this, messengers from Jabesh went to Gibeah of Saul; and Saul put the people in three companies; and they came into the midst of the host in the morning watch, and slew the Ammonites until the heat of the day, so that two of them were not left together. After the victory, Samuel said, Let us go to Gilgal and renew the kingdom, and there they made Saul king. (1 Sam. xi.) Nahash afterwards showed kindness unto David: he died about B.C. 1037. When David sent to comfort his son Hanun, the princes of the children of Ammon suspected that he had some design, and the king took David's servants, and treated them shamefully. The Ammonites then hired the Syrians of Beth-Rehob, and 20,000 footmen of Zoba, and of king Masech 1000 men, and of Ishob 12,000. To oppose this force, David sent out Joab, who defeated the Ammonites. Upon this, Hadarezer, the Syrian king, sent and brought out the Syrians from beyond the Euphrates, but David took 700 chariots of the Syrians, and slew 40,000 horsemen, and Shobach, the captain of their host; so the kings that were servants to Hadarezer, made peace with Israel, and the Syrians feared to help the children of Ammon any more. About B.C. 1035, David sent Joab and his servants, and all Israel, and they defeated the children of Ammon, and besieged Rabbah, their metropolis. And Joab took first the royal city, or that part which contained the palace, and the reservoirs and springs of water. And Joab sent messengers to David, and said, I have taken the city of waters, now gather the rest of the Israelites and take Rabbah: lest I take the city and it be called after my name. David took Rabbah, and got the king's crown, the weight whereof was a talent of gold, with the precious stones: and it was set on David's head, and he brought forth the spoil of the city in great abundance. His treatment of the conquered people was harsh and cruel. About B.C. 896, the Ammonites, Moabites, and others came against Jehoshaphat, to battle in Hazazon-tamar, which is En-gedi. Jehoshaphat proclaimed a fast, and Judah gathered themselves together to ask help of the Lord, which came by the discord of the hostile forces. For the children of Ammon and Moab stood up against their comrades, the inhabitants of mount Seir; every one helped to destroy another, and none escaped. And Jehoshaphat and his people stripped off precious jewels from the dead bodies, and riches, more than they could carry away, and they were three days in gathering the spoil. And on the fourth day, they blessed the Lord in the valley of Beracha. Therefore, the name of the same place is called Beracha, which means blessing. And the fear of God was on all the kingdoms, when they heard that the Lord had fought against the enemies of Israel.

(2 Chron. xx.) About B.C. 760, Jotham fought with the king of the Ammonites, and compelled the Ammonites to give him the same year 100 talents of silver, and 10,000 measures of wheat, and 10,000 of barley; so much they paid also the second and the third year. (2 Chron. xxvii.)

From the prophetic writings, we derive some further information as to the history and character of the Ammonites. They are accused by Amos (i. 13.) of the barbarous practice of ripping up women with child. Their destruction is predicted by Isaiah, xi. 14; Zephaniah, ii. 9; Jeremiah, xlix. 1-5; Ezekiel, xxv.

About 600 B.C., bands of the Ammonites came with Nebuchadnezzar against Jerusalem, (2 Kings xxiv. 2.) and exulted in the downfall of their once powerful and inveterate enemy. About 457 B.C., Ezra enforced the Mosaic law (Deut. xxiii. 2.), that an Ammonite should not enter into the congregation of the Lord, even to his tenth generation. Consequently, Ezra separated many Israelites from their Ammonitish wives, (Ezra ix. x.) King Solomon, at an earlier period, had violated the Mosaic law, by having Ammonitish women in his harem. (1 Kings xi. 1.) Ezra's adherence to the law of Moses excited the hostility of the Ammonites to the rebuilding of Jerusalem, which was ridiculed by Tobiah the Ammonite, who said, even that which they build, if a fox go up, he shall even break down their stone wall. (Neh. iv. 3.) Nehemiah, who was also a vigorous reformer, cursed and smote those Israelites who had married wives of Ammon and plucked off their hair (Neh. xiii.), about 434 B.C. Judas the Maccabee fought, during the reign of Antiochus Epiphanes, about 164 B.C., many battles with Timotheos, the mighty captain of the Ammonites, who had much people. Judas took their town, Jazar: (Maccabees v.) Rabbah had been already destroyed by Antiochus the Great. (Polyb. v. 71.) In the days of Justin Martyr, the Ammonites were still very numerous; and in the days of Origen, the Ammonites and Edomites went under the general name of Arabians (lib. v.)

Their metropolis, רַבְּבָה Rabbah, which we must suppose had been rebuilt, is called by Josephus Παββα, by Eusebius Ἀμμα, by Polybius and Stephanus Byzantinus, Παββαρῶν, and Philadelphia; and by the Arabians, Am-mān. Abulfeda describes its extensive remains (*Tab. Syriae*, ed. Köhler, p. 91), which were found by Seetzen under the name of *Robba* and *Rabba*. (Zach's *Monatliche Correspondenz*, xviii. p. 433.) These, however, belong to the Greek period, not to the ruins of ancient Rabbah. [See PHILADELPHIA.] The surrounding country was called *Arabia Philadelphiensis*. The bed of Og king of Bashan belonged to the curiosities of Rabbah; but how it got there, we are not told. [See AMORITES.] Nine cubits were the length, and four the breadth thereof, (Deut. iii. 2.)

The Ammonites were uncircumcised (Jer. ix. 26.), and worshipped Molech or Milcom, and their idolatry was, by the Ammonitish wives of Solomon, introduced among the Israelites. (1 Kings xi. 7, 33. 2 Kings xxiii. 13.)

Of their kings, we know only Nahash and Hanun, in the time of David, and Baalis, contemporary with Nebuchadnezzar. (Jer. xl.)

AMMO'NIUM. [See SIWAH.]

AMMO'NIUM, a name proposed by Davy to express the supposed metal which amalgamates with mercury, when it is electrified in contact with ammonia, as already described; he thought it scarcely possible to conceive that a substance, which forms with mercury so perfect an amalgam, should not be metallic.—*Phil. Trans.*, 1808.

Although few chemists have adopted this opinion, its probability is still maintained by Berzelius: he considers ammonium to be a compound of 1 volume of azotic gas and 4 volumes of hydrogen gas; these being nearly the proportions of them contained in the mixture of ammoniacal and hydrogen gases, obtained when the amalgam is decomposed by water.

The property of amalgamating with mercury is the only circumstance which denotes an approximation to the nature of a metal in the substance in question; while there are difficulties almost insuperable to such a conclusion. No metal has hitherto been decomposed; mercury is the only substance with which the supposed ammonium has been combined, and it has never been procured in a separate state.

A'MNESTY is a word derived from the Greek ἀμνηστία, which, literally, signifies nothing more than non-remem-

brance. This word, however, both in the Greek and in the Latin language, into which latter it was introduced, (see *Aurelian. Vopisc.* chap. 39.) acquired a more particular signification, and was used to denote a declaration of the person or persons who had newly acquired or recovered the sovereign power in a state, by which they pardoned all persons who composed, supported, or obeyed the government which had been just overthrown. A declaration of this kind may be either absolute and universal, or it may except certain persons specifically named, or certain classes of persons generally described. Thus, in Athens, when Thrasybulus had destroyed the oligarchy of the Thirty Tyrants, and had restored the democratical form of government, an exceptive amnesty of past political offences was declared, from the operation of which the Thirty themselves, and some few persons who had acted in the most invidious offices under them, were excluded. So when Bonaparte returned from Elba in 1815, he published an amnesty from which he excluded thirteen persons, whom he named in a decree published at Lyons. The act of indemnity, passed upon the restoration of Charles II., by which the persons actually concerned in the execution of his father were excluded from the benefit of the royal and parliamentary pardon, is an instance of an amnesty from which a class of persons were excepted by a general description and not by name. Of a like nature was the law passed by the French Chambers in January, 1816, upon the return of Louis XVIII. to the throne of France after the victory at Waterloo, which offered a complete amnesty to 'all persons who had directly or indirectly taken part in the rebellion and usurpation of Napoleon Bonaparte,' with the exception of certain persons, whose names had been previously mentioned in a royal ordinance as the most active partisans of the usurper. It was objected to this French law of amnesty, that it did not point out with sufficient perspicuity the individuals who were to be excepted from its operation. Instead of confining itself to naming the offenders, it went on to except whole classes of offences, by which means a degree of uncertainty and confusion was occasioned, which much retarded the peaceable settlement of the nation. 'In consequence of this course,' says M. de Chateaubriand in a pamphlet published soon after the event, 'punishment and fear have been permitted to hover over France; wounds have been kept open, passions exasperated, and recollections of enmity awakened.' The act of indemnity, passed at the accession of Charles II., was not liable to this objection, by the distinctness of which, as Dr. Johnson said, 'the flutter of innumerable bosoms was stilled,' and a state of public feeling promoted, extremely favourable to the authority and quiet government of the restored prince.

AMOL, a Persian town in the province of Mazanderan. It stands on the river Herauz, which flows through it, about twelve miles from the southern shore of the Caspian sea, in 36° 30' N. lat. 52° 23' 55" E. long. from Greenwich. There is a bridge of twelve arches, and eight feet in width, over the river, the stream of which is full and rapid. The only interesting building in Amol is the ruin of a mausoleum erected by Shah Abbas over the remains of his maternal ancestor, Seyed Quwām-u-deen, otherwise called Meer Buzurg, king of Saree and Amol, who died in 1378. It was a structure of considerable magnificence, till the greater part of it was thrown down by an earthquake about twenty years ago. There were formerly other extensive ruins in the town and neighbourhood, but of these the only traces now existing are some mounds of earth. Amol is divided into eight muhulehs or districts, and in the winter, when it is fullest, may contain from 35,000 to 40,000 inhabitants. The houses are between 4000 and 5000 in number. The bazars are large and well supplied; but the only traffic carried on is with the country and villages in the immediate vicinity. Amol is the capital of a government of the same name, which yields a revenue of between 7000*l.* and 8000*l.* sterling. The mountains approach close to the town on the south; the space between it and the sea is thickly covered with wood; there are many groups of houses among the trees, but no regular roads. (See *Travels and Adventures in the Persian Provinces on the southern Banks of the Caspian Sea*, by James B. Fraser, 4to., 1826.)

AMO'MUM, a genus of plants bearing aromatic seeds and belonging to the natural order *Scitumineæ*. It consists of species having white flowers collected in close heads, which arise from the base of the leaves, and only just raise themselves above the ground; the lower lip of the flower is

very broad and large compared with the others, and the other has a two-lobed crest; the seeds are contained in a loose skin, and are enclosed in a rather tough capsule which is separated into three cells by as many membranous partitions, and finally opens into three valves. The leaves are of a broadly lanceolate or oval figure tapering to the point, and enveloping the stem like a sort of sheath.

The cardamoms, grains of Paradise, and mellagetta pep-

per of the shops, a class of highly aromatic pungent seeds, are produced by different species of amomum, especially by *A. cardamomum*, and *A. grana Paradisi*. In Sierra Leone there is among other species one called *A. grandiflorum*, the seeds of which have a stimulant flavour resembling that of camphor. The following figure of this and of the cardamom plant will furnish an idea of the general characters of the genus.

[*Amomum Grandiflorum*.]

- a. The lip and a back view of the anther. c. Calyx.
b. A front view of the anther. d. Stigma.

[*Amomum Cardamomum*.]

AMOOD, a pergunnah, belonging to the East India Company, in the province of Gujerat. It is a narrow strip, lying along the eastern shore of the Gulf of Cambay, between the western boundary of the Broach pergunnah and the southern boundary of the Jumboossee pergunnah, formed by the Dhadur river. Its extreme length is 30, and its general breadth 8 miles; but it is much narrower at the north-east end: its superficial content is 221½ square miles.

This area is partitioned in unequal proportions among 44 villages. Rather more than one half of the land is under cultivation: a large portion of that which is considered unproductive, consists of an extensive salt-flat, which lies along the north-western boundary of the pergunnah, and adjoins the sea. The only port, Ghundhar, is situated in this quarter; its trade is now insignificant, although the town must at some remote period have been a considerable place, as appears from the extensive ruins around it. The lands of Ghundhar are entirely neglected, not an acre has been cultivated for many years, although much of it is considered fit for tillage: the inhabitants are chiefly occupied in making salt. In the cold season salt is produced in the pans in about a month, but in the warm season the evaporation goes on much more rapidly. The gross produce of the salt-pans is thus divided: 50 per cent. to the government, 35 per cent. to the proprietors of the pans, and the remaining 15 per cent. in various proportions among different native functionaries.

Every foot of land in this and the other pergunnahs of the district belongs to some one or other of the villages

of which the pergunnah is composed. The strict observance paid to the preservation of their boundaries by the inhabitants of every village in this quarter is remarkable. These boundaries are commonly marked by strips of land 20 or 30 yards in breadth, which are left waste; and though they are sometimes ploughed up by common consent, the line remains as fully recognized as if it bore the most visible marks. Every pergunnah has its own hereditary officers of revenue and record, and every village has its establishment of public servants.

Some part of the soil of Amood is sandy, and of a light brown colour, but the greater part is of superior fertility, and well adapted for wheat, which, with millet, forms the principal food of the inhabitants. The wheat is of the bearded kind, and grows to the height of 18 inches: there are commonly about 50 grains of wheat in each ear. It is sown late in September, or early in October, and ripens in March, when it is pulled up by the roots. An experiment was tried in 1819, to ascertain the produce of wheat, which was ascertained to be equal to only 336 pounds, or 6 bushels per acre. The field on which this experiment was made had been fallow the preceding year, but had not been manured. The seed is sown very thin, at the rate of only two-thirds of a bushel to the acre, and the ripening grain is subject to the depredations of very large birds, called kullums, which visit the country just before harvest in large flocks. Numerous herds of antelopes are also commonly met with, and are very destructive to the crops. A considerable quantity of cotton is produced.

The population of Amood has been ascertained to amount

to 16,347 souls, of whom 3203 are Mohamedans, and 13,144 are Hindoos. The number of houses in the pergunnah is 4075; of cows and buffaloes, 5908; of oxen, 4639; of ploughs, 1752, and of carts, 889.

This pergunnah was obtained by cession from the late Peishwa Dowlut Rao Scindia, under the treaty of Poona, dated 13th June, 1817. (Report of Colonel Williams in *Appendix to the Report of the House of Commons* (1832) on the Affairs of the East India Company.)

AMORITES (אֲמֹרִי, *Amoraios*), the most powerful tribe

of the Canaanites, or the aborigines of Palestine. The name Amorites seems sometimes to be used for all the Canaanites, as all the British are by foreigners sometimes called Englishmen. Canaan begat Sidon his first-born, and Heth, and the Jebusite, and the *Amorite*, and the Girgasite, and the Hivite, and the Arkite, and the Sinite, and the Arvadite. These are the sons of Ham. (Gen. x. 15-20.) The Amorites are mentioned among the ten nations whose country was given to the seed of Abraham. (Gen. xv. 19-21.) The Amorites dwelt chiefly in the mountains, which afterwards belonged to the tribe of Judah. (Numb. xiii. 29.

Deut. i. 20.) The name אֲמֹרִי has been explained by Simonis and Gesenius by *mountaineer*: אֲמֹר means *head, top of a tree*, and אֲמֹר head of a tribe, emir, chieftain, prince.

Perhaps the name was given because the *Amorites* were like *Emirs* at the head of the Canaanitish tribes. Others have translated אֲמֹר *amarus, bitter, embittered*, from אָמַר; or *rebel*, from אָמַר; or *talking, eloquent*, from אָמַר. The word אֲמֹר occurs in the singular number only, which is often used collectively for the whole Amoritish nation. Some Amorites dwelt in the plains bordering upon the tribe of Dan, and others between the rivers Jordan and Arnon. The river Arnon was the border between Moab and the Amorites. (Num. xxi. 13.) Of the cities of the Amorites it was said to the people of Israel, 'Thou shalt save alive nothing that breatheth: but thou shalt utterly destroy the Hittites, *Amorites*, Canaanites, Perizites, Hivites, and Jebusites, as the Lord thy God has commanded thee, that they teach you not to do after all their abominations, which they have done unto their gods.' (Deut. xx. 16.) Even their sons and their daughters have they burnt in the fire to their gods. (Deut. xii. 31.) 'Whoever of the children of Israel or of the strangers that sojourn in Israel, giveth of his seed unto Moloch shall be put to death.' (Lev. xx. 2.)

The Amorites were of tall stature. According to Amos, (ii. 9.) they were high as cedars and strong as oaks. This poetical description is illustrated by the historical statement, that the size of the iron bedstead of the Amoritish king, Og of Bashan, was nine cubits by four. (Deut. iii. 11.) Hence we may infer, that Og's stature was gigantic, although it did not fill his iron bedstead any more than the Stuarts filled the enormous bedsteads at Hampton Court. But it is most likely that this bedstead, as it is called, was a kind of divan. But the biblical statement could not bridle the flights of rabbinical imagination, who, regardless of the sacred text which they professed to illustrate, surpassed all the extravagancies of Arabian, Persian, and Indian poesy; in the *Jalkut Shimon*, Moses told the angel of death that Sihon and Og were so vast, that they could not be drowned in the deluge, its waters reaching only to their ancles. Sihon was harder than a wall and taller than any tower, and no creature on earth could withstand his strength. But after the demon with whom he was connected had been chained, Israel was let loose upon him and discomfited him and the Amorites. The Sevachir declares that Og, putting his hand against the windows of heaven, and his feet against the fountains of the great deep, stopped the deluge, until the water being made hot scalded the giant to the bone, who now, mounting the ark, rode out the storm. If Og retained his appetite, he must have been an inconvenient passenger, for his bill of fare was daily 1000 oxen, 1000 head of game, and 1000 measures of wine. According to Berachoth, Og, having ascertained that the camp of Israel was three miles in extent, tore up a sheet of rock of the same size, with the view to crush all arts of war, by putting this extinguisher upon the history of Israel. But whilst Og held the rock over his head it was bored by insects, broken into pieces, which fell on his shoulders, and nearly strangled the giant. Joshua,

watching this dilemma, took an axe ten ells long, and being himself ten ells high, he jumped another ten ells, struck Og in the ancle and lamed him for life, until he was finally destroyed at the age of 900 years. (*Blackwood's Magazine*, 1832, p. 744.)

So much seems certain, that in antient times the natives of Syria exceeded in stature the inhabitants of the desert and of Egypt.

The four confederate kings (Genesis xiv.), who plundered Sodom and Gomorrah and took Lot captive, smote also the Amorites that dwelt in Hazzazon Tamar אֲמֹרִי הַחֲזָזוֹן

amputation or cutting of the palm tree, which place was afterwards called Engeddi, אֶנְגֶּדִי *Kid's Eye* or *Kid's*

Fountain, on the western borders of the Dead Sea, (B.C. 1913.) Abram dwelt at this time in the plain of Mamre the Amorite, the brother of Eshcol and Aner, Abram's confederates. Hence we perceive that the Amorites chiefly inhabited the country afterwards occupied by the tribe of Judah, (Gen. xiv. 13.) and that they were on friendly terms with Abram.

The inhabitants of Gideon were Amorites. By feigning to send ambassadors from a great distance they obtained peace with the Israelites under Joshua about the year B.C. 1451. (See Joshua ix.) For making this confederacy Gibeon was attacked by five kings of the Amorites; but Joshua chased them from Gibeon to Bethhoron, Azekah, and Makedah, where, according to Joshua, (x. 11.) more died from hailstones than by the sword of the Israelites. But after all this, the Amorites retained so much power, that they forced (B.C. 1425) the children of Dan into the mountain, for they would not suffer them to come down to the valley. 'But the Amorites would dwell in Mount Heres in Ajalon, and in Shaalvim; yet the house of Joseph prevailed so that they became tributaries. And the coast of the Amorites was from the going up to Akrahim, from the rock and upward.' (Judges i. 34-36.) The remarkable fact, that the Israelites conquered the mountains sooner than the plains is explained (Judges i. 19.): it was because the inhabitants of the plain had chariots of iron.

About the year B.C. 1120 there was peace between Israel and the Amorites. The Gibeonites (to whom seven descendants of Saul were delivered by David about the year B.C. 1020, that they might revenge themselves for Saul's atrocities) were of the remnant of the Amorites whom Joshua had made hewers of wood and drawers of water. (Jos. ix. 2 Sam. xx.) Another branch of the Amorites dwelt between the rivers Jordan and Arnon. (Num. xxi. 13, xxii. 36: Judges xi. 18.) Here Moses and the children of Israel had smitten two kings of the Amorites, namely, Sihon, who dwelt at Heshbon, and Og, king of Bashan, in the plain east of Jordan. These kings had refused to let the Israelites pass through their borders. But it appears that these Amorites were not extirpated, and that their descendants formed, even during the time of the Maccabees, a distinct tribe; for we read in Josephus's *Antiquit.* (xiii. chap. 1.) that the Amorites (Αμαραιοὶ καὶ ἄλλοι) from Medaba fell suddenly upon the camp of Johannes Gaddis, when he was conveying, according to the command of his brother Jonathan, the baggage of the Jewish host to the Nabathæan Arabs who roved between the Euphrates and the Red Sea. Simon and Jonathan revenged the death of their brother Johannes by falling suddenly upon the splendid train of an Amoritish bridegroom who was leading his bride, the daughter of a rich Arabian from Gabatha to Medaba. On this occasion 400 men, women and children were killed.

AMOS, the prophet, was a native of the town of Thekot, which was about six miles south of Bethlehem. He was not a prophet's son, but a herdsman, and a gatherer of camore fruit, and the Lord took him as he followed the flock, to prophesy unto Israel. (Amos vii. 14, 15.) Therefore, Amos mentions the kingdom of Judah only incidentally, and hence Dr. Coke, Dr. Adam Clarke, and several commentators before them have vaguely conjectured Amos to be a native of the kingdom of Israel. Amos and his visions concerning Israel in the days of Uzziah, King of Judah, and in the days of Jeroboam II., King of Israel, two years before the earthquake. (Amos i. 1.) This earthquake is mentioned by Zechariah, (xiv. 5.) 'Ye shall flee like as ye fled from before the earthquake in the days of Uzziah, King of Judah,' which happened, according to the

opinions of the later Jews, when Uziah went into the temple to burn incense upon the altar, and Azariah, the priest, went in after him, and with him fourscore priests, valiant men who withstood Uziah, and said, it appertaineth not unto thee to burn incense, but to the priests that are consecrated: go out of the sanctuary. Then Uziah was wroth, leprosy rose in his forehead, and the priests thrust him out from thence. (2 Chron. xxvi.) According to Josephus, (*Antiquit.* ix. 10. § 4.) the earthquake began during the king's altercation with the priests. A ray of the sun, according to the story, fell through a fissure of the temple into the face of the king and struck him with leprosy. The western part of Mount Olivet rolled four stadia or furlongs to the east side of the mountain, covered many streets and destroyed the king's gardens.

It is probable that the prophecies of Amos were delivered between the years 798—784 before Christ.

With this period, the contents of the book of Amos agree, for the borders of Israel extended from Hamath to the Arnon (Amos vi. 14.), and the vices, which the prophet denounces, are such as usually predominate during periods of temporal prosperity and security. Isaiah, Hosea, and Amos were contemporaries. The opinion that Isaiah, a member of the royal family, was a son of Amos the herdsman, arose from a confusion of the prophet whose name is *Gamos* גָּמוֹס (signifying, burden or burdened) with the

word *יִמְנָה* (strong) *Amots*, the name of the father of

Isaiah. The Greeks wrote both names *Amōs*.

In the Book *ἡ ἐκείνου τῶν προφητῶν τοῦ ἱεροῦ καὶ τοῦ αὐτοῦ*, which has been published with the works of Epiphanius, who was bishop of Constantia, in Cyprus, at the end of the fourth century, we read that Amos, born at Thekoa, in the land of Zebulon, the father of Isaiah, was wounded with a sword by Amaziah the priest, at Bethel, whom he had reproved for worshipping calves. The son of Amaziah struck him with a bludgeon on the head, so that he died two days after returning to his country, where he was buried with his fathers. The land of Zebulon may here signify the *sandy region*, the desert of Thekoa, which extends from the south of Jerusalem to the Persian Gulph, at the entrance of which Thekoa was situated, surrounded with tolerable pastures. Or it means the country of *שֶׁכֶל*

the Idumean, Gen. xxxvi. 20, which the Latins called *terra Sobail*. (See H. A. Hamakeri, *Commentatio in libellum de vita et morte Prophetarum*. Amst. 1833. In *Instituti regii Commentarii*.)

Many having repeated St. Jerome's saying, that Amos was 'rude in speech, but not in knowledge,' Bishop Louth, in his twenty-first lecture, shows that Amos was not behind the chief prophets in eloquence. The book of Amos is written in an excellent Hebrew style, but the orthography differs occasionally from the usual standard. Amos, the herdsman, has taken many figures from pastoral life, but he alludes also to history, geography, and astronomy. Thus we see that knowledge, in olden times, was not confined to those who, like Isaiah, were of the blood royal, or priests like Jeremiah, but extended sometimes even to herdsmen.

Chapters i. ii. describe the approaching judgment of Jehovah, which rolls like a thunder-storm over the surrounding states, Damascus, Philistia, Tyrus, Edom, Ammon, Moab, touches upon Judah, and halts over Israel, on account of its injustice, immorality, idolatry, and stubbornness against the providence of Jehovah.

Chapters iii., iv., v., and vi. contain the predictions of the punishment of Israel; and chapters vii.—ix. visions of judgment, in which is interwoven the history of Amaziah's opposition, who said unto Amos, O thou seer, go, flee thee away into the land of Judah, and there eat bread and prophesy there.

The canonical authority of Amos rests upon the internal character of his work, upon the united testimony of the Jewish and Christian church, and upon the use which the apostles made of Amos (v. 25, 26, in Acts vii. 42., Amos 11., and in Acts xv. 16.). Philo, Josephus, and the others quote Amos among the minor prophets, and even the author of the book of Tobit (ii. 6.) quotes a passage from Amos, mentioning his name.

AMOY, a celebrated port of China, in the province of Kien, in 20° 45' north latitude and 118° east longitude.

In Mandarin dialect, the name of the place is *Hea-mun*, which is pronounced by the natives *Ha-moy*.

The district in which this flourishing town, the emporium of the commerce of the province, is situated, is one of the most barren in all China, and not only yields nothing for exportation, but is dependent even for the necessities of life on the neighbouring island of Formosa, which has been described as the granary of the eastern coast of China. Notwithstanding this serious disadvantage, the merchants of Amoy are among the most wealthy and enterprising in the Chinese empire; they have formed connexions all along the coast, and have established commercial houses in many parts of the eastern archipelago. Most of the Formosian colonists emigrated from the district of Amoy, with capital supplied by its merchants, and in proportion as the island has flourished, so has Amoy increased in wealth and importance.

During the south-west monsoon, the merchants of Amoy freight their vessels at Formosa with sugar, which they sell at various ports to the northward, returning home with cargoes of drugs. They maintain commercial relations with Manilla, as well as with Tonquin and Cochin China: they annually employ forty large junks in trading with Bangkok, the capital of Siam. Junks of the largest class—some of them 800 tons burden—go to Borneo, Macassar, Java, and the Soo-loo islands; and many of them annually visit Singapore, in order to procure goods of British manufacture.

This port has not always been closed against European vessels. According to the records of the East India Company,—'The King of Tywan, on taking Amoy in 1675, issued a proclamation inviting both Chinese and foreign merchants to trade thither, exempting them from the payment of all duties for three years.' Many vessels, in consequence, resorted to the port, but the exemption was speedily revoked. In 1681, the town was taken by the Tartars, but Europeans were still allowed to trade thither, and continued to do so until 1734, when the exactions of the Mandarins deterred them from continuing so unprofitable an intercourse; and when an English ship went there, ten years after, many vain endeavours and much fruitless discussion were employed to induce the Chinese to trade, so that the vessel was obliged to proceed to Bengal for a cargo.

The ship *Amherst* visited Amoy last year (1832) with no better success; it appears, however, that the obstacles to her trading all proceeded from the authorities, and not from the people, by whom our countrymen were received in the most friendly manner. The harbour of Amoy is spacious and secure. (Lords' Report of 1820-21, relative to the Trade with the East Indies and China; and Report of Proceedings on a Voyage in the Ship *Amherst* to the Northern Ports of China, by Mr. H. H. Lindsay.)

AMPELI'DEÆ, one of the names of the vine tribe. [See VITES.]

AMPHIBIA, (from the Greek word *ἀμφίβιος*, which signifies *having a double life*;) a zoological term employed in different senses by different writers. In common conversation we are accustomed to call all mammals, such as seals, otters, beavers, &c., amphibious, whose organization disposes them to resort indifferently either to the land or water for procuring food and other purposes, or whose habits are at once terrestrial and aquatic; thus we usually denominate the common campagnol (*Arvicola amphibia*) and white-bellied shrew (*Sorex fodiens*), the water-rat and water-shrew respectively, and consider them in every respect as amphibious animals. But in this sense of the word every land-animal is more or less amphibious, for all resort occasionally to the water, and with the single exception of man, all appear to have an instinctive power of swimming. Previous to the time of Linnæus, the earlier naturalists attached no more definite meaning to the word than that which was sanctioned by popular custom, and which, it will be observed, is more properly expressed by the term aquatic. The great Swedish philosopher, however, rejected this vague and improper signification, and applied the term generally to the third class of his system of zoology, which comprised not only all the animals since more properly denominated reptiles, such as the tortoises, lizards, serpents, and frogs, but likewise the cartilaginous fishes. Linnæus was evidently ignorant of the true characters and natural limits of this class of animals; the term *amphibia* was certainly very applicable to many of the genera and species which it embraced, but with

regard to the great majority of them it was an absolute misnomer. The shark and the ray are as incapable of existing out of the water, as many of the common lizards are of living in it, and consequently neither the group which Linnæus proposed to establish, nor the name by which he designated it, has been adopted by more recent zoologists. The cartilaginous fishes have been referred to the other aquatic tribes, with which their habits and organic conformation naturally connect them, and the remainder of the class, which stands in Gmelin's celebrated edition of the *Systema Naturæ* under the name *amphibia*, is admitted into modern systems under the more appropriate designation of reptiles.

Taken in its strict and literal sense, the term amphibious would apply only to such animals as have the power of living indifferently, at the same time, either upon land or in water. To fulfil this condition it is necessary that a truly amphibious animal should be provided with the means of breathing in either of these elements, that is, that it should simultaneously possess both lungs and gills. Now there are four genera of batrachian reptiles which actually do possess this extraordinary double apparatus for extracting the principle which supports animal life indifferently from either element; and these, as Baron Cuvier has justly observed, comprise in reality the only known vertebrated animals which are truly amphibious. They are the *axolotls*, the *menobranchi*, and the *sirens*, all of which inhabit the rivers and lakes of America, and the *proteus* which is found in subterranean streams connecting certain lakes in Carniola and Hungary. 'The existence and simultaneous action of gills and lungs in these animals,' says Baron Cuvier, in a note to the *Règne Animal*, 'can no longer be doubted as one of the most clearly established facts in natural history; I have before me the lungs of a siren of three feet in length, in which the vascular apparatus is as well developed and as complicated as in any other reptile, yet nevertheless this siren had gills as complete as any other species.' These then are the only strictly amphibious reptiles; but if we were disposed to take the term in a little more extended sense, it might, without impropriety, be applied to the entire order of reptiles which M. Brongniart, and after him all modern naturalists, denominate *batrachians*, because all these animals, without exception, breathe by means of gills in their tadpole state, and only acquire lungs when they assume the more mature and perfect form of reptiles.

Beyond this, however, the term cannot with propriety be extended to the reptiles in general, because these animals, though the limited quantity of their respiration enables them to remain under water for a much longer period than birds or mammals, can no more absolutely dispense with breathing than the higher classes, and like them would inevitably be drowned if prevented for any length of time from coming to the surface to breathe. For further information upon this subject, see REPTILE, BATRACHIANS, and AQUATIC ANIMALS.

AMPHIBOLITE, a name sometimes given to the simple mineral more commonly called hornblende, and which was introduced by Haiiy, the mineralogist, who uselessly changed many names. He called hornblende *amphibole*, because it is easily mistaken for augite, another simple mineral closely allied to it in composition, from ἀμφίβολος, *amphibolos*, equivocal.

AMPHICTYONS, members of a celebrated council in ancient Greece, called the Amphictyonic Council.

According to the popular story, this council was founded by Amphictyon, son of Deucalion, who lived, if he lived at all, many centuries before the Trojan war. It is supposed by a writer quoted by Pausanias, x. 8., to derive its name, with a slight alteration, from a word signifying 'settlers around a place.' Strabo, who professes to know nothing of its founder, says that Acrisius, the mythological king of Argos, fixed its constitution, and regulated its proceedings. Amidst the darkness which hangs over its origin, we discover with certainty, that it was one of the earliest institutions in Greece. No full or clear account has been given of it during any period of its existence by those who had the means of informing us. The fullest information is supplied by Æschines the orator; but before any attempt is made, by the help of some short notices from other writers, and of conjecture, to trace its earlier history, it may not be amiss to state what is certainly known of this council as it existed in his time.

According to Æschines, the Greek nations which had a

right to be represented in the council, were the Thessalians, Bœotians, Dorians, Ionians, Perrhæbians, Magnesians, Locrians, Cœtæans, Phthiots, Malians, Phocians. Each nation was represented by certain sovereign states, of which it was supposed to be the parent: thus Sparta, conjointly with other Dorian states, represented the Dorian nation. Amongst the states thus united in representing their common nation, there was a perfect equality. Sparta enjoyed no superiority over Dorium and Cytinium, two inconsiderable towns in Doris, and the deputies of Athens, one of the representatives of the Ionian nation, sat in the council on equal terms with those of Eretria in Eubœa, and of Priene, an Ionian colony in Asia Minor. From a rather doubtful passage in Æschines, *De Fals. Leg.* 43. compared with a statement in Diodorus, xvi. 60. it seems that each nation, whatever might be the number of its constituent states, had two, and only two votes. The council had two regular sessions in each year, meeting in the spring at Delphi, and in the autumn near Pylæ, otherwise called Thermopylæ; but special meetings were sometimes called before the usual time. From its meeting at Pylæ, a session of the Amphictyons was called a Pylæa, and the deputies were called Pylagoræ, that is, councillors at Pylæ. There were also deputies distinguished by the name of Hieromnemons, whose office it was, as their name implies, to attend to matters pertaining to religion. Athens sent three Pylagoræ and one Hieromnemon. The former were appointed for each session; the latter probably for a longer period, perhaps for the year, or two sessions. The council entertained charges laid before it in relation to offences committed against the Delphic god, made decrees thereupon, and appointed persons to execute them. These decrees, as we learn from Diodorus, xvi. 24. were registered at Delphi. The oath taken by the deputies bound the Amphictyons not to destroy any of the Amphictyonic cities, or to debar them from the use of their fountains in peace or war; to make war on any who should transgress in these particulars, and to destroy their cities; to punish with hand, foot, voice, and with all their might, any who should plunder the property of the god, (the Delphic Apollo,) or should be privy to, or devise anything against that which was in his temple. This is the oldest form of the Amphictyonic oath which has been recorded, and is expressly called by Æschines the ancient oath of the Amphictyons. It has inadvertently been attributed to Solon by Mr. Mitford, who has apparently confounded it with another oath imposed on a particular occasion. An ordinary council consisted only of the deputed Pylagoræ and Hieromnemons; but on some occasions at Delphi, all who were present with the Amphictyonic deputies to sacrifice in the temple and consult the oracle of the god, were summoned to attend, and then it received the name of an *ecclesia* or assembly. Beside the list of Amphictyonic nations given by Æschines, we have one from Pausanias which differs a little from that of Æschines, and another from Harpocration which differs slightly from both. The orator, whilst he speaks generally of twelve nations, names only eleven. Strabo agrees with him in the larger number. It is further remarkable, that whilst Æschines places the Thessalians at the head of his list, Demosthenes, *De Pac.* p. 62. expressly excludes them from a seat in the council.

Æschines has left us much in the dark as to the usual mode of proceeding in the Amphictyonic sessions; and we shall look elsewhere in vain for certain information. It should seem that all the Pylagoræ sat in the council and took part in its deliberations; but if the common opinion mentioned above, respecting the two votes allowed to each nation, be correct, it is certain that they did not all vote. The regulations according to which the decisions of the twelve nations were made can only be conjectured. We know that the religious matters which fell under the jurisdiction of the Amphictyonic body were managed principally, at least, by the Hieromnemons, who appear, from a verse in Aristophanes, *Nub.* 613., to have been appointed by lot, but we are not as well informed respecting the limits which separated their duties from those of the Pylagoræ, nor respecting the relative rank which they held in the council. (See Æsch. *contr. Ctes.* p. 68—72. *Fals. Leg.* p. 43.) The little that is told is to be found for the most part in the ancient lexicographers and scholiasts, or commentators, who knew perhaps nothing about the matter, and whose accounts are sufficiently perplexing to give room for great variety of opinions among modern writers. Some have

seemed to themselves to discover that the office of the Hieromnemons was of comparatively late creation, that these new deputies were of higher rank than the Pylagoræ, and that one of them always presided in the council; others again have supposed, what, indeed, an ancient lexicographer has expressly asserted, that they acted as secretaries or scribes. Two Amphictyonic decrees are found at length in the oration of Demosthenes on the Crown, both of which begin thus: 'When Cleinagoras was priest, at the vernal Pylæa, it was resolved by the Pylagoræ and the Synedri (joint councillors) of the Amphictyons, and the common body of the Amphictyons.' Some have assumed that Cleinagoras the priest was the presiding Hieromnemon, and others that the Hieromnemons are comprehended under the general name of Pylagoræ. Æschines again has mentioned a decree in which the Hieromnemons were ordered to repair at an appointed time to a session at Pylæa, carrying with them the copy of a certain decree lately made by the council. Of the council, as it existed before the time of Æschines, a few notices are to be found in the ancient historians, some of which are not unimportant. According to Herodotus, vii. 200. the council held its meetings near Thermopylæ, in a plain which surrounded the village of Anthela, and in which was a temple dedicated to the Amphictyonic Ceres; to whom, as Strabo tells us, ix. 429. the Amphictyons sacrificed at every session. This temple, according to Callimachus, *Ep.* 41. was founded by Acrisius; and hence arose, as Müller supposes in his history of the Dorians, (vol. i. p. 289, English translation,) the tradition mentioned above.

We are told by Strabo, ix. 418. that after the destruction of Crissa by an Amphictyonic army, under the command of Eurylochus, a Thessalian prince, the Amphictyons instituted the celebrated games, which from that time were called the Pythian, in addition to the simple musical contests already established by the Delphians. Pausanias also, x. 7., attributes to the Amphictyons, both the institution and subsequent regulation of the games; and it is supposed by the most skilful critics, that one occasion of the exercise of this authority, recorded by Pausanias, can be identified with the victory of Eurylochus, mentioned by Strabo. According to this supposition, the Crissæan, and the celebrated Cirrhæan war, are the same, and Eurylochus must have lived as late as B.C. 591. But the history of these matters is full of difficulty, partly occasioned by the frequent confusion of the names of Crissa and Cirrhæa.

From the scanty materials left us by the ancient records, the following sketch of the history of this famous council is offered to the reader, as resting on some degree of probability:—

The council was originally formed by a confederacy of Greek nations or tribes, which inhabited a part of the country afterwards called Thessaly. In the lists which have come down to us of the constituent tribes, the names belong for the most part to those hordes of primitive Greeks which are first heard of, and some of which continued to dwell north of the Malian bay. The bond of union was the common worship of Ceres, near whose temple at Anthela its meetings were held. With the worship of the goddess was afterwards joined that of the Delphic Apollo; and thenceforth the council met alternately at Delphi and Pylæa. Its original seat and old connexions were kept in remembrance by the continued use of the term Pylæa, to designate its sessions wherever held: though eventually the Delphic god enjoyed more than an equal share of consideration in the confederacy. It may be remarked that the Pythian Apollo, whose worship in its progress southwards can be faintly traced from the confines of Macedonia, was the peculiar god of the Dorians who were of the Hellenic race; whilst the worship of Ceres was probably of Pelasgic origin, and appears at one time to have been placed in opposition to that of Apollo, and in great measure to have retired before it. There is no direct authority for asserting that the joint worship was not coeval with the establishment of the council; but it seems probable from facts, which it is not necessary to examine here, that an Amphictyonic confederacy existed among the older residents, the worshippers of Ceres, in the neighbourhood of the Malian bay, before the hostile intruders with their rival deity were joined with them in a friendly coalition. The council met for religious purposes, the main object being to protect the temples and maintain the worship of the two deities. With religion were joined, according to the customs of the times, political objects; and the jurisdiction of the Amphictyons extended to matters which con-

cerned the safety and internal peace of the confederacy. Hence the Amphictyonic laws, the provisions of which may be partly understood from the terms of the Amphictyonic oath. Confederacies and councils, similar to those of the Amphictyons, were common among the ancient Greeks. Such were those which united in federal republics the Greek colonists of Asia Minor, of the Æolian, Ionian, and Dorian nations. Such also was the confederacy of seven states whose council met in the temple of Neptune in the island of Calauria, and which is even called by Strabo, viii. 374, an Amphictyonic council.

The greater celebrity of the northern Amphictyons is attributable partly to the superior fame and authority of the Delphic Apollo; still more, perhaps, to their connexion with powerful states which grew into importance at a comparatively late period. The migrating hordes, sent forth from the tribes of which originally or in very early times the confederacy was composed, carried with them their Amphictyonic rights, and thus at every remove lengthened the arms of the council. The great Dorian migration especially planted Amphictyonic cities in the remotest parts of Southern Greece. But this diffusion, whilst it extended its fame, was eventually fatal to its political authority. The early members, nearly equal perhaps in rank and power, whilst they remained in the neighbourhood of Mounts Ceta and Parnassus, might be willing to submit their differences to the judgment of the Amphictyonic body. But the case was altered when Athens and Sparta became the leading powers in Greece. Sparta, for instance, would not readily pay obedience to the decrees of a distant council, in which the deputies of some inconsiderable towns in Doris sat on equal terms with their own. Accordingly in a most important period of Grecian history, during a long series of bloody contests between Amphictyonic states, we are unable to discover a single mark of the council's interference. On the other hand, we have from Thucydides i. 112, a strong negative proof of the insignificance into which its authority had fallen. The Phocians (B.C. 448) possessed themselves by force of the temple of Apollo at Delphi; were deprived of it by the Lacedæmonians, by whom it was restored to the Delphians; and were again replaced by the Athenians. In this, which is expressly called by the historian a sacred war, not even an allusion is made to the existence of an Amphictyonic council. After the decay of its political power there still remained its religious jurisdiction; but it is not easy to determine its limits or the objects to which it was directed. In a treaty of peace made (B.C. 421) between the Peloponnesians and the Athenians (Thucyd. v. 17), it was provided that the temple of Apollo at Delphi, and the Delphians, should be independent. This provision, however, appears to have had reference especially to the claims of the Phocians to include Delphi in the number of their towns, and not to have interfered in any respect with the superintendence of the temple and oracle, which the Amphictyons had long exercised in conjunction with the Delphians. We have seen that the Amphictyons were charged in the earliest times with the duty of protecting the temple and the worship of the god. But the right of superintendence, of regulating the mode of proceeding in consulting the oracle, in making the sacrifices, and in the celebration of the games, was apparently of much later origin, and may, with some probability, be dated from the victory gained by Eurylochus and the Amphictyonic army. The exercise of this right had the effect of preserving to the council permanently a considerable degree of importance. In early times the Delphic god had enjoyed immense authority. He sent out colonies, founded cities, and originated weighty measures of various kinds. Before the times of which we have lately been speaking, his influence had been somewhat diminished; but the oracle was still most anxiously consulted both on public and private matters. The custody of the temple was also an object of jealous interest on account of the vast treasures contained within its walls.

The Greek writers, who notice the religious jurisdiction of the council, point our attention almost exclusively to Delphi; but it may be inferred from a remarkable fact mentioned by Tacitus, *Ann.* iv. 14, that it was much more extensive. The Samians, when petitioning in the time of the Emperor Tiberius for the confirmation of a certain privilege to their temple of Juno, pleaded an ancient decree of the Amphictyons in their favour. The words of the historian seem to imply that the decree was made at an early period in the existence of Greek colonies in Asia Minor, and

he says that the decision of the Amphictyons on all matters had at that time pre-eminent authority.

The sacred wars, as they were called, which were originated by the Amphictyons in the exercise of their judicial authority, can here be noticed only so far as they help to illustrate the immediate subject of inquiry. The Cirrhæan war, in the time of Solon, has already been incidentally mentioned. The port of Cirrhæa, a town on the Cirræan bay, afforded the readiest access from the coast to Delphi. The Cirrhæans, availing themselves of their situation, grievously oppressed by heavy exactions the numerous pilgrims to the Delphic temple. The Amphictyons, by direction of the oracle, proclaimed a sacred war to avenge the cause of the god; that is, to correct an abuse which was generally offensive, and particularly injurious to the interests of the Delphians. Cirrhæa was destroyed, the inhabitants reduced to slavery, their lands consecrated to Apollo, and a curse was pronounced on all who should hereafter cultivate them. We are told that Solon acted a prominent part on this occasion, and that great deference was shown to his counsels. Mr. Mitford, indeed, has discovered without help from history, which is altogether silent on the subject, that he was the author of sundry important innovations, and that he in fact remodelled the constitution of the Amphictyonic body. He has even been able to catch a view of the secret intentions of the legislator, and of the political principles which guided him. But in further assigning to Solon the command of the Amphictyonic army, he is opposed to the direct testimony of the ancient historians.

From the conclusion of the Cirrhæan war to the time of Philip of Macedon, an interval exceeding two centuries, we hear little more of the Amphictyons, than that they rebuilt the temple at Delphi, which had been destroyed by fire B.C. 548; that they set a price on the head of Ephialtes, who betrayed the cause of the Greeks at Thermopylæ, and conferred public honours on the patriots who died there; and that they erected a monument to the famous diver Scyllias as a reward for the information which, as the story goes, he conveyed under water from the Thessalian coast to the commanders of the Grecian fleet at Artemisium. If Plutarch may be trusted, the power of the Amphictyons had not at this time fallen into contempt. When a proposition was made by the Lacedæmonians to expel from the council all the states which had not taken part in the war against the Persians, it was resisted successfully by Themistocles, on the ground that the exclusion of three considerable states, Argos, Thebes, and the Thessalians, would give to the more powerful of the remaining members a preponderating influence in the council dangerous to the rest of Greece.

After having, for a long period, nearly lost sight of the Amphictyons in history, we find them venturing, in the fallen fortunes of Sparta, to impose a heavy fine on that state as a punishment for an old offence, the seizure of the Theban Cadmeia, the payment of which, however, they made no attempt to enforce. In this case, as well as in the celebrated Phocian war, the Amphictyonic council can be considered only as an instrument in the hands of the Thebans, who after their successful resistance to Sparta, appear to have acquired a preponderating influence in it, and who found it convenient to use its name and authority, whilst prosecuting their own schemes of vengeance or ambition. Though the charge brought against the Phocians was that of impiety in cultivating a part of the accursed Cirrhæan plain, there is no reason to think that any religious feeling was excited, at least in the earlier part of the contest; and Amphictyonic states were eagerly engaged as combatants on both sides. For an account of this war, the reader is referred to a general history of Greece. The council was so far affected by the result, that it was compelled to receive a new member, and in fact a master, in the person of Philip of Macedon, who was thus rewarded for his important services at the expense of the Phocians, who were expelled from the confederacy. They were, however, at a subsequent period restored, in consequence of their noble exertions in the cause of Greece and the Delphic God against the Gauls. It may be remarked, that the testimony of the Phocian general Philomelus, whatever may be its value, is rather in favour of the supposition that the council was not always connected with Delphi. He justifies his opposition to its decrees, on the ground that the right which the Amphictyons claimed was comparatively a modern usurpation. In the case of the Amphissians, whose crime was similar to that of the Phocians, the name of the Am-

phictyons was again readily employed; but Æschines, who seems to have been the principal instigator of the war, had doubtless a higher object in view than that of punishing the Amphissians for impiety.

The Amphictyonic council long survived the independence of Greece, and was, probably, in the constant exercise of its religious functions. So late as the battle of Actium, it retained enough of its former dignity at least, to induce Augustus to claim a place in it for his new city of Nicopolis. Strabo says that in his time it had ceased to exist. If his words are to be understood literally, it must have been revived; for we know from Pausanias (x. 8.), that it was in existence in the second century after Christ. It reckoned at that time twelve constituent states, who furnished in all thirty deputies; but a preponderance was given to the new town of Nicopolis, which sent six deputies to each meeting. Delphi sent two to each meeting, and Athens, one deputy: the other states sent their deputies according to a certain cycle, and not to every meeting. For the time of its final dissolution, we have no authority on which we can rely.

It is not easy to estimate with much certainty the effects produced on the Greek nation generally, by the institution of this council. It is, however, something more than conjecture, that the country which was the seat of the original members of the Amphictyonic confederacy, was also the cradle of the Greek nation, such as it is known to us in the historical ages. This country was subject to incursions from barbarous tribes, especially on its western frontier, probably of a very different character from the occupants of whom we have been speaking. In the pressure of these incursions, the Amphictyonic confederacy may have been a powerful instrument of preservation, and must have tended to maintain at least the separation of its members from their foreign neighbours, and so to preserve the peculiar character of that gifted people, from which knowledge and civilization have flowed over the whole western world. It may also have aided the cause of humanity; for it is reasonable to suppose that in earlier times, differences between its own members were occasionally composed by interference of the council; and, thus, it may have been a partial check on the butchery of war, and may at least have diminished the miseries resulting from the cruel lust of military renown. In one respect, its influence was greatly and permanently beneficial. In common with the great public festivals, it helped to give a national unity to numerous independent states, of which the Greek nation was composed. But it had a merit which did not belong to those festivals in an equal degree. It cannot be doubted that the Amphictyonic laws, which regulated the originally small confederacy, were the foundation of that international law which was recognised throughout Greece; and which, imperfect as it was, had some effect in regulating beneficially national intercourse among the Greeks in peace and war, and, so far as it went, was opposed to that brute force and lawless aggression, which no Greek felt himself restrained by any law from exercising towards those who were not of the Greek name. To the investigator of that dark but interesting period in the existence of the Greek nation, which precedes its authentic records, the hints which have been left us on the earlier days of this council, faint and scanty as they are, have still their value. They contribute something to those fragments of evidence with which the learning and still more the ingenuity of the present generation are converting mythical legends into a body of ancient history.

AMPHIDESMA, among zoologists, is the name of a genus of marine bivalve shells, which live in the sand or the sea-coast of tropical climates. The shells are oval or rounded, sometimes rather twisted and slightly gaping behind. They have two hinge teeth in each valve, and often distinct compressed lateral ones. The elastic cartilage is placed in a small triangular cavity just behind the hinge teeth. The animals of these shells are unknown; but they are supposed to have long syphons, like the Tellens, as the shells have a broad, deep inflation on the back edge or the submarginal scar, formed by the attachment of the muscles which retract these syphons, as in the Tellens from which genus it simply differs in the position of its cartilage.

Lamarck gave the name of *Amphidesma* to this genus because he observed that it had a ligament and a cartilage, which he regarded as peculiar to this genus, he having like the rest of the zoologists before the appearance of the

Conchological Observations in the *Zoological Journal*, considered what is usually called the ligament of bivalves as only one substance. It is, however, two substances, of very different structure and use; the outer, or ligament, being inelastic, and only employed to keep the two valves together, is formed of fibres extending from the edge of one valve to the other; but the cartilage is elastic and formed of perpendicular fibres, like the prismatic crystalline-structured shell, its use being to separate the valves from one another when the muscles which keep them closed are relaxed. When the valves are closed, this part is compressed by their edge. For this purpose it is sometimes, as in the shell under consideration, placed in a small triangular cavity close to the hinge, when the shell is said to have an internal cartilage, the ligament being still in its usual place. In other shells it is placed, along with the ligament, on the margin of the valves, and is pressed, when the valves are closed, against the ligament itself, which forms its outer wall. The resistance which the ligament offers is the means of opening the shell. The cartilage has opaline reflections, and the cartilages of some large shells, as the mother-of-pearl shells, are sold by the jewellers under the name of *Peacock-stone*, or *black opals*. They are not so much used now as formerly, but they are still much sought after on the Continent, especially in Portugal.

AMPHILA, BAY OF, a bay extending for about sixteen miles along the west coast of the Red Sea, in 14° 30' N. lat. and 41° E. long. from Greenwich. Mr. Salt has given a chart of it on a large scale, from a survey, in his *Voyage to Abyssinia*, quarto, London, 1814. There are thirteen islands in the bay, the largest of which, called also Amphila, lying near its south-eastern extremity, is not quite a mile in length. Of these islands one only is a rock of calcareous stone; the others are all composed of corallines, madrepores, and other marine alluvia, strongly cemented together, and covered with a thin layer of soil. None of them are now inhabited, though on one, called Kutto, there are the ruins of some houses. On the main land at the bottom of the bay is the village of Duroro, and farther to the south-east, the smaller village of Madir. Between these and the sea is a sort of thick jungle of rack trees. This district was formerly part of the old kingdom of Dankali, and still retains that name. Mr. Salt thinks it probable that Amphila is not a native word, but a corruption of the Greek *Ἀντιφίλον λιμήν*, mentioned by Strabo. Casaub. p. 771. (Salt's *Abyssinia*, chap. iv.)

AMPHIPOLIS, an ancient Greek city, on the left or eastern bank of the river Strymon, just below its egress from the lake Kerkine, now called Takino, and about three miles above its influx to the sea. This town was at first called Ennea Hodoi (the nine ways), and belonged to the Edonians, a Thracian people. The first attempt at colonization here was by Aristagoras of Miletus, who failed in the attempt, (B.C. 497.)

The Athenians next made an unsuccessful attempt, (B.C. 465,) and sustained a severe loss, but they took Ennea Hodoi in the year 437 B.C., and established there a colony. They enlarged and fortified the town, to which Hagnon, the leader of the colony, gave the name of Amphipolis, because the river Strymon flowed round a large part of it, forming nearly a circle; a wall was built across, and thus the town was defended on every side. This is Thucydides' account, (lib. iv. cap. 102) which some geographers have interpreted as if the town had stood between two branches of the river, which do not exist. In several maps, also, the Angitas, which flows from the eastward into the lake Kerkine, is mistaken for the Strymon which enters it from the north. The latter is called Struma by the Bulgarian inhabitants who are very numerous in this district. During the Peloponnesian war, (B.C. 424,) the Lacedæmonians, under their general Brasidas, took Amphipolis. Cleon, being sent by the Athenians to retake it, was beaten by Brasidas in a combat under the walls of the town, where both generals lost their lives. The importance of Amphipolis was derived from its situation on the banks of a navigable river, a short distance from the sea, and from its neighbourhood to the gold mines of Mount Pangeus, and to the fine forests of Kerkine, from which, even now, many cargoes of timber are annually shipped at the mouth of the Strymon. Amphipolis was taken by Philip, king of Macedonia. Amphipolis has long been in ruins, and a village of about 100 houses, called Jeni-Keui, inhabited by Turks and Greeks, occupies part of its former site. It lies about

twenty miles south-east of the large town of Serres, the residence of a bey, and fifty-four miles north-east of Salonichi. M. Cousinéry, formerly French consul at Salonichi gives an account of the ruins of Amphipolis, which he repeatedly visited, and a view of the site of the ancient town, and the course of the river, &c., in his *Voyage dans la Macédoine*. He found some traces of the town wall some remains of sculpture, and a curious Greek inscription, being a decree of banishment against two citizens of Amphipolis, one of whom, Stratocles, is perhaps the envoy of that name mentioned by Demosthenes in the first Olynthiac, who became obnoxious to Philip for his attachment to Athens. A number of medals are still found among the ruins of Amphipolis. M. Cousinéry visited also the ruins of Eion, formerly a town near Amphipolis, on the left bank and at the mouth of the Strymon. The great Roman road, called the Via Egnatia, ran through Amphipolis, or perhaps rather through Eion.

AMPHIPROSTYLE. This is an architectural term, compounded of three Greek words. It is used to designate structures having the form of an ancient Greek or Roman parallelogramic temple, with a prostyle or portico on each of its ends or fronts, but with no columns on its sides or flanks. The plan of the temple of Jupiter Panhellenius, at Ægina, given with the article *ÆGINA*, will exactly exemplify this arrangement, if the flanking rows of columns forming the lateral ambulatories are supposed to be removed. This would leave (independently of the internal hypæthral disposition in the particular instance) an exact representation of what is intended, in its ordinary acceptation, by the term Amphiprostyle, or, to retain the Greek form, Amphiprostylos; and the structure, having thus four columns in front, would be an *amphi-tetra-prostylos*. (See also *PROSTYLE*.)

AMPHISBÆNA, (from *ἀμφίβηνα*, which signifies, an animal that can walk in both directions,) in zoology a genus of serpents, distinguished by their bodies having nearly the same uniform thickness from the head to the extremity of the tail, by their small mouths and extremely diminutive eyes, their remarkably short tails, and the numerous rings of small square scales which completely surround this organ and the body. A range of small pores runs in front of the vent, which is situated nearly at the end of the tail; the jaws alone are provided with a single row of small conical teeth, the palate being without any; and even those of the jaws are few and distant from one another. They are, moreover, destitute of fangs, and are consequently harmless and inoffensive, living for the most part upon ants and other small insects, and inhabiting ant-hills and burrows which they themselves construct under ground. The nature of their food does not require these animals to possess the power of dilating the mouth and gullet to the extraordinary extent that is observed in the boas, pythons, and other serpents in general, which live for the most part upon animals proportionally much larger than themselves, and in order to admit the huge mouthful have the upper and under jaws both equally moveable upon the cranium. In the amphispæna, on the contrary, the upper jaw is fixed to the skull and intermaxillary bones, as in birds and mammals, so that the head remains constantly in the same plane with the body,—a form which permits the animal to move equally well in either direction, namely, either backwards or forwards, and which has acquired for it the name by which it is distinguished.

The head of the amphispæna is so small, and the tail so thick and short, that it is difficult at first sight to distinguish one from the other, and this circumstance, united to the animal's habit of proceeding either backwards or forwards as the occasion may require, has given rise to the popular belief very generally spread throughout Brazil and other parts of South America, the native countries of this genus, that it possesses two heads, one at each extremity, and that it is impossible to destroy the animal by simple cutting, as the two heads mutually seek one another in case of such a serious accident, and soon re-unite as if nothing had happened. Ignorance is the parent of superstition and absurdity, and one wonder naturally produces twenty: it is not therefore surprising that, among an ignorant and credulous people, the singularity of the amphispæna's form and habits should have given rise to this and a multitude of other gross fictions. 'Another snake,' says Stedman, in his History of Surinam, 'which I also observed here, is about three feet long, and annulated with different colours; it is called amphispæna'

from the supposition of its having two heads; and the truth is, that from its cylindrical form the head and tail so much resemble each other that the error is almost pardonable; besides which, the eyes are nearly imperceptible. This is the snake which, being supposed blind, and vulgarly said to be fed by the large ants already described, is in this country honoured with the name of King of the Emmets. The flesh of the amphibœna, dried and reduced to a fine powder, is confidently administered as a sovereign and infallible remedy in all cases of dislocation and broken bones; it being very naturally inferred that an animal which has the power of healing an entire amputation in its own case, should at least be able to cure a simple fracture in the case of another. Two centuries have scarcely passed since opinions equally credulous and absurd were universally prevalent among the most enlightened nations of Europe, when grave and learned physicians administered the bezoar or rhinoceros' horn with as much confidence as the simple Brazilian at present does the powdered flesh of the amphibœna.

The genus amphibœna, as at present defined, contains only American species, which are confined to Brazil, Surinam, and other tropical parts of the continent. Of these the following are the principal.

1. The *A. fuliginosa*, the first, and still the best known species of the whole genus, is, like all the other amphibœnas, confined to the hotter regions of South America, and does not inhabit Ceylon or any other part of the East Indies, as Linnæus and Lacepède have erroneously supposed, and asserted on the authority of Seba. The general colour of this serpent is a deep brown varied with shades of white, more or less intense according to the difference of the individual and the season of casting the old and acquiring

[*Amphibœna fuliginosa*.]

the new external skin. It grows to the length of eighteen inches or two feet, of which, however, the tail measures only an inch or fifteen lines. The body is surrounded by upwards of two hundred rings, and the tail by twenty-five or thirty; the eyes are covered and almost concealed by a membrane, which, added to their naturally diminutive size, has given rise to the popular opinion that the animal was entirely deprived of sight; an opinion extended with no better reason to the common blind-worm (*Anguis fragilis*). It lives upon worms and insects, particularly ants, in the mounds of which it usually conceals itself. The antipathy which most people entertain against serpents in general has given rise to a belief common among travellers, that this species is venomous, but without the slightest foundation in reality, as it is entirely destitute of fangs, and its teeth in other respects so small as to be incapable of inflicting a wound.

2. *A. alba*, so called from its colour, which is that of uniform pale straw without any marks or spots. The head of this species is short and thick, and its mouth small. The body usually measures from one foot six to one foot nine or ten inches, and is surrounded by two hundred and twenty-three rings; the tail is from an inch and a half to two inches in length, and is surrounded by sixteen or eighteen rings. The thickness of the body seldom exceeds that of a man's fore-finger, and is uniform throughout its whole

length; that of the former species, on the contrary, equals the thickness of a child's wrist of ten or twelve years old. The *A. alba* inhabits the same localities and lives in the same manner as the *A. fuliginosa*, from which indeed it differs only in size, colour, the proportionate length of the tail and body, and in having the mouth provided with a greater number of teeth, all, however, equally small and weak.

3. *A. cæca*, a species mentioned by Baron Cuvier in the second edition of the *Règne Animal*, but without any detailed description. It inhabits the island of Martinique, and is said to be entirely deprived of sight, at least M. Cuvier was unable to discern any trace of eyes. He supposes it, nevertheless, to be identical with the *Amphibœna vermicularis* of Spix, which that naturalist describes as having eyes scarcely perceptible.

The works of Prince Maximilian of Neuwied and M. Spix on the general zoology and erpetology of Brazil contain descriptions of three or four smaller species of amphibœnas.

AMPHI'SCII, literally *double shadowed*, a Greek term applied by ancient astronomers to the inhabitants of the torrid zone, with whom the sun passes the meridian at noon, sometimes on the north, sometimes on the south, of the zenith, and whose shadows at noon are therefore turned to the south during one part of the year, and to the north during the remainder.

AMPHITHE'ATRE, the name by which a species of structure much used by the Romans, and combining the forms and some of the uses of the antient theatre and circus.

[Amphitheatre of Verona.]

is generally distinguished; indeed most of the Roman classical writers apply to it the name of circus also. A distinction, however, is now always made; the term amphitheatre being applied to the species of structure here referred to, and circus being restricted to the Roman stadium or hippodrome. [See CIRCUS.]

The name amphitheatre seems intended to convey the idea of a double theatre; but what is termed a theatre is, with reference to its original uses, more strictly an odeum, and what we call an amphitheatre was truly a theatre. The one was for hearing music and recitations, and the other for seeing sights,—as the words import. [See THEATRE.]

The form of the amphitheatre is, on the plan, that of an ellipsis, with a series of arcaded concentric walls, separating corridors which have constructions with staircases and radiating passages between them. It encloses an open space called the arena, either on, or a very little above or below the level of the surface of the ground on which the structure is raised. From the innermost concentric wall,—which bounds the arena, and which will be from ten to fifteen feet above its level,—an inclined plane runs upwards and outwards over the intermediate wall, staircases, and corridors, to a gallery or galleries over the outermost corridors. The inner and upper part of the inclined plane is covered with a graduated series of benches following the general form of the plan; these are intercepted at intervals by radial passages leading by a more easy graduation to and from the staircases which pass through the substructions of the benches to the corridors. These corridors, in the principal stories, continue uninterruptedly all round the edifice, and afford easy access to, and egress from, every part. In cases where the radiating passages through the bank of benches were few, concentric platforms or precincts went round to make the communications complete. The external elevation of an amphitheatre is almost dictated by its internal arrangement and construction, and it generally falls into two or more stories of open arches, which are necessary to give light and air to the corridors and staircases.

The Amphitheatre seems to have been contrived for the more convenient exhibition of such shows as were confined

[Longitudinal Elevation of the Flavian Amphitheatre, or Colosseum, Rome.]

[Longitudinal Section—on the line from a to b of the plan of an Amphitheatre—The Colosseum.]

[Ground Plan of an Amphitheatre—The Colosseum.]

throughout to the same place, such as combats, which could not be seen advantageously along the length of the circus; and moreover the circus had not the lofty stereobate, podium, or cincture, to protect the spectators from the savage and powerful brute animals which were frequently used in the public shows of the Romans. Indeed, it is reported that this defect was a cause of the abandonment of the circus for such exhibitions as required the use of wild beasts. The great length also of the circus would be a sufficient reason for adopting the more compressed and lofty form given to the amphitheatre, whose arrangement admits of a far greater number of persons being brought within a smaller area, and consequently within more convenient view of the arena.

At first, and for some time, amphitheatres were constructed of timber. Several accidents occurred, indeed, in consequence of the use of such, from fire, and from their incapacity to bear the weights they were subjected to; and, in one instance, it is related by Tacitus, (*Annal.* iv. 62.) that an amphitheatre of this kind fell during the exhibition of the shows, in the town of Fidenæ, when 50,000 persons were either killed or hurt. Afterwards they were more securely and more permanently constructed of brick or stone, according to the facilities the place afforded, or the means of the people at whose expense the structures were laid.

It was in the latest period of the Republic that the Romans were debased by the gladiatorial and other shows which led to the use and construction of amphitheatres; and to the gratification of this passion for demoralizing public spectacles may be attributed, in some degree, its eventual overthrow, in all but form, and the establishment of the despotism of the emperors. All the powerful men in the state who aimed still higher, sought favour with the people by these barbarous entertainments; and the sums expended and the numbers of men and beasts engaged, and for the most part destroyed, in furnishing them seem almost incredible.

The difference in the national characteristics of the Greeks and Romans is by nothing more forcibly illustrated than by the constant indications of theatres or odcœums which mark the sites or immediate vicinities of ancient Greek cities, and the remains of amphitheatres which are common to those of the Romans.

To save unnecessary expense, the Grecian theatre was formed on or in the side of a hill, whenever the locality would afford this advantage; the seats were generally cut in the living rock, and such constructions added before it in the formation of the orchestra and proscenium and their accessories, as were absolutely necessary to complete the theatre. The amphitheatre of the Romans was raised, for the most part, within the town or city, on the level plain, of costly magnificence, and generally of enormous extent, while their theatres are in every respect secondary, and of inferior importance. Indeed, theatres for music and the drama are seldom found among the remains of purely Roman cities, but almost every Roman colony, and even camp, bears indications of a constructed or excavated amphitheatre. The great mother city of Rome herself can hardly be said to exhibit the remains of a theatre, unless it be that which is called the theatre of Marcellus; and even this appears to have been more used for games of the circus, or amphitheatrical shows, than for dramatic representations, and is not of extraordinary extent. But the Colosseum would contain from eighty to a hundred thousand persons;—and the little city of Pompeii, which has indeed two theatres, has, moreover, an amphitheatre, whose arena alone would contain them both. The Grecian cities of Sicily, on the contrary, exhibit remains and indications of spacious theatres where those of the amphitheatres of their Roman masters are few and unimportant; and the old cities of Greece itself, and the Grecian cities of Asia Minor, are almost entirely free from the pollution of the latter species of structure,—the Roman garrisons appearing to have contented themselves with castrensian or camp-built amphitheatres alone. Of this sort,—the Castrensian amphitheatre,—we have indications still existing in England;—the principal are at Cirencester and Dorchester; but these were originally little more than mere excavations, or turf-built cinctures made up with what walling was absolutely necessary to form the grand concentric bank of benches. In the provinces of Gaul,—both transalpine and cisalpine,—Nîmes and Verona, by the remains of their amphitheatres, show how much more completely the inhabitants were nationalized, or Romanized, than were those of Greece or of Britain.

There is, perhaps, no species of structure peculiar to the Romans, with the details of which we are so well informed, as of those of the amphitheatre, and there is hardly any one of which we have fewer descriptions by ancient writers. The remains which still exist in various places tell us much more plainly what they were than the most elaborate descriptions can do; and although there is no example of an amphitheatre in complete preservation, or even nearly so, yet the existing specimens preserve the various parts so completely, that there is but little difficulty in supplying from one of them what is defective in another. Still there are minor particulars of which we must remain ignorant, unless we take them from such descriptions as exist, or supply them from analogy. We know of no sort of ancient edifice, generally, in which so much ingenuity is displayed in the arrangement, or so much skill in the construction, as were exemplified by the Romans in the design and execution of the amphitheatre; but here the merit ends,—for in architectural demerit, the external composition of the amphitheatre is hardly outdone by the triumphal arch, which is the worst that ever was imagined before the *revival*, as it is called, of architecture in the fifteenth century.

As the most remarkable, and one of the most perfect in its details, of the remaining examples of the amphitheatre, that which is known as the Colosseum at Rome is here used to illustrate this kind of edifice; the plan and elevation are almost entirely made out from the existing remains; and the section also, to a certain extent, as well as from the analogy afforded by other examples and from probability. The vignette sketch at the head of this article is a view of the amphitheatre of Verona, as it exists, looking down into it; this will aid the section in giving an idea of the arrangement of the benches, and the mode of access to them.

The form of the external periphery of the plan is that of an ellipsis, whose conjugate diameter, or minor axis, is to the transverse, or major axis, as five to six, nearly,—the length through, from outside to outside of the external wall, being 620 feet, and the breadth to the same extent, 513 feet; but as these dimensions are variously stated by different authorities, something may be allowed for inaccuracy, and the proportion between one diameter and the other may be fairly assumed in the original draft to have been as above stated. Indeed, if the projection of the substructions be added to each diametrical length, that proportion will be produced as nearly as possible, and in this the architect appears to have erred; for if he had any reason for the proportion assumed between the conjugate and transverse, or between the breadth and length of the ellipsis, it should have been taken on the extent of the outer wall, so that its periphery might be true, which is not the case. Of course, in the diminishing series of concentric walls the proportion of the ellipsis is continually altering, so that the diameters of the arena are as five to eight, as nearly as may be, the length being 287 feet, and the breadth 180 feet. The difference between the external and internal diameters, of 333 feet, or 166 ft. 6 in. at each end, is occupied by four corridors and two blocks of radiating substructions,—in, or between, which are the staircases and ways from the outer corridors to the inner, and to the arena, together with the concentric or encircling walls which gird the structure, separate the corridors, and enclose the arena. Two of the surrounding corridors lie together, or adjoin each other, on the outer side; and in this particular, the Colosseum exceeds every other structure of the kind of which we have any knowledge, all the rest having but one only; it thus acquires a second gallery, as may be perceived by referring to the section, in which also, it is singular. The space covered by this immense edifice will be found to be little short of six acres.

The outer encircling wall is pierced with eighty openings, leaving, of course, an equal number of piers; every opening is arched, and in or against every pier is a column projecting about half its diameter, and supporting an entablature which runs in an unbroken line all round the structure. With the exception of the four central openings, which lie on the diameters of the ellipsis, and are each nearly two feet wider than the rest, all the openings are very nearly the same, their width being 14 feet 6 inches. An exactly similar series of arches, diminished only in proportion to the smaller extent of the ellipsis, separates the second corridor from the first; and another, bearing the same relation to the second series that the second does to the first, or outer, bounds the second corridor. The inner faces of the outer piers, both faces of the

piers of the intermediate series, and the outer faces of the piers of the innermost series, have pilasters projecting from them, corresponding in height with the external columnar ordinance, and bearing a moulded architrave, from the top of which semicircular arches are turned over the corridors and continued all round the edifice. The accompanying plan and section exhibit the general arrangement of the corridors here described, though the details cannot, on so small a scale, be made obvious. The elevation shows how a second and third columnar ordinance, with corresponding and nearly similar arched intervals, superimpose the lowest, and each other, and that each of these two upper ordinances rests upon a continued stylobate or dado, which is broken into every interval, or under every column. The section indicates the repetition of the double series of outer corridors in every story, or behind every one of the three columnar ordinances, and above the outermost corridor in the third story, a mezzanine, or small middle story, for a corridor behind the first, and under the second, or upper, gallery. The same diagrams show that the third story of columns is superimposed by a pilastrated ordinance on a continued and recessed dado also, with a deep plinth: they show, moreover, that a bold and massive entablature crowns the whole elevation, and runs its cornice round in one unbroken line.

From the third series of eighty piers, on the ground story, as many walls, with the exceptions to be noticed, run inwards to the third concentric corridor, which is arched over as the outer ones are; the walls are continued on the other side of it to the fourth or innermost corridor, which is bounded on the other side by the massive wall of the podium encircling the arena, and is also arched over, though it is not so lofty as the other three corridors are. Between the radiating walls of the two blocks separating the second from the third, and the third from the fourth corridors, are, of course, as many intervals. Some of these form the traversing passages; and the rest, in the outer block, contain the staircases which lead to the upper concentric corridors and so onward to the upper benches and galleries;—in the inner block are those which lead to the lower benches, and small staircases in the thickness of the innermost wall conduct to the benches immediately on the podium. The benches extend in one long graduated and concentric series from the podium up to the level of the second story of the outer corridors, and over all the constructions within the second of them: they are bounded above by a wall which is pierced with doors. These give access from the upper and inner corridor, to the radiating flights of steps which intercept the benches at intervals, and cut them up into wedges, by which name in Latin, *cunei*, the divisions thus made were distinguished. This encircling wall has windows in it also, which may have been requisite to aid in ventilating the immense area; or they may have been intended merely to afford a view of the arena to persons who could not find room on the benches. The section shows that the radiating flights of steps intercepting the benches do not run through their whole extent, but are themselves intercepted and taken up again,—other lines or flights commencing immediately, and at intermediate heights. Access is given to these flights at their upper ends, by doorways from the corridors behind, sometimes directly, and sometimes by means of the internal staircases; and in most cases a short reversed flight of steps is made on the outside of the doorways, or vomitories, as they are termed, to afford headway, and avoid intercepting the benches further back than could be possibly helped. Almost every thing that appears in the section above the level of the third story, except the external wall itself, is restored from analogy and conjecture. The peristyle, or encircling range of columns before the upper gallery, is entirely from conjecture; but for the galleries themselves there is sufficient evidence in the existing indications of stairs, and in the toothings of the remaining walls and piers. The benches in the grand series were probably of stone, perhaps of marble, but in the galleries it is most likely they were of wood, and graduated so as to give their occupiers a view of the arena.

The most distinguished seats were those on the podium, and these were assigned to the emperor,—whose place was, by way of eminence, called the *suggestum*,—and to the senators, to foreign ambassadors, and to the great officers of the state. The *cunei*, or wedges, behind and above, were assigned to different classes, according to their rank, station, and tribe. The Vestal virgins had one of the best positions assigned to them, and with them sat such ladies

of high rank as could obtain the advantage, but the women generally occupied the galleries.

As the plan indicates, the four central entrances,—those which lie on the ends of the diameters of the ellipsis,—are wider than the corresponding parts of the rest of the structure. They were arcaded through, and finished more carefully, especially those leading from the sides, or on the minor axis; these, it is most likely, were reserved for those persons who went to the seats on the podium, and as they gave access also to the arena, they would of necessity be more strictly guarded.

It does not appear that any part of the structure above the level of the ground, and outside of the arena, was appropriated as dens for the beasts which were used in the shows; for indeed, the corridor leading to the principal seats in the amphitheatre must have been traversed by them in their way to the arena, if that were the case. Substructions were discovered and excavated a few years ago over the whole extent of the arena; these lead to a belief that it was floored with wood, so that the animals required for the day may have been kept in dens under the floor, and allowed to issue at traps in it. But some have supposed dens ranged all round the arena, within its surface and below the podium, from which the beasts would issue to the combat directly.

In the Colosseum the great crowning cornice of the external elevation is pierced through at regular intervals with square holes or mortises, from which grooves are cut down through the rest of the entablature flush with the outer surface of the wall; and every mortise and groove is immediately above a strong projecting stone or corbel at about two thirds the height of the pilastrated ordinance. These are supposed to have been used to insert and receive poles to carry an awning strained over the whole enclosure to protect the spectators from the sun and from rain. If this were the case, there must have been some intermediate support for it of which we are not aware; such an extent of cloth or canvass could hardly have been borne in that manner.

The external elevation is composed,—as it has been already described, and as the elevation indicates,—of three series or stories of attached or engaged columns with their usual accessories, and a pilastrated ordinance, forming a species of attic, which is pierced with windows,—one in every other interspace. The lowest ordinance of columns rests on the upper step of the substructions, or on the ground floor of the structure; it is of what is termed the Doric style or order, but in the debased Roman manner, and its entablature wants the distinguishing feature of that style, the triglyph,—indeed, it may be more aptly designated by the Vitruvian term Tuscan, since it certainly is not Doric, and may be of the latter. The intervening arches are semicircular; they spring from moulded imposts, and have moulded archivolt on their outer faces. The second ordinance is in the Roman Ionic style, having voluted capitals to the columns; and the third is in the Corinthian or foliated style: these, as before stated, rest upon continued, but broken or recessed, stylobata, but their entablatures are, like the rest, perfectly unbroken throughout, and the arches in the intercolumniations in both, correspond exactly—except in minor details—with those of the lowest or Doric ordinance. The pilasters have foliated capitals also, and are called composite; they rest on deep plinths under which there is a continued and recessed dado superimposing the Corinthian entablature;—this dado is pierced with holes or small windows alternating with those of the ordinance above, to give light to the corridor behind the lower and under the upper gallery on the inside. The crowning entablature is made bold and effective by deep modillion blocks or consoles occupying the whole depth of the frieze.

The style of these architectural decorations is, for the most part, as rude and tasteless as it well can be. The storied columnar ordinances, too, besides being themselves bad in detail, are bad in the composition, or in their collocation with arches; for—taking them separately—the columns of each ordinance are too far apart to support their entablature sufficiently, which, therefore, itself appears weak, and they look straggling and inefficient. Taken together, the ordinances but repeat these faults, and have in the whole a poor and mean effect; the shelf-like cornices of their entablatures cut up, and destroy the simplicity of, the elevation, which no observer would suppose to be, as it is, nearly 160 feet high. The storied series of arches with simple blocking courses alone, and continued unbroken *stylobata* under each arcaded story, and with the broad and simple

attic—without pilasters—but crowned nevertheless by the fine bold entablature, would have been a far nobler composition. The practice here exemplified, nevertheless, which may be fairly termed a vice, seems to have pervaded the architecture of the Romans, for either columnar or pilastred ordinances, and sometimes, as in this case, both, are found on almost all the examples that remain to us of their amphitheatres. Internally, however, the amphitheatre must have been strikingly grand and impressive; here none of the littlenesses of storied columns appeared, but the long unbroken lines of the podium, and the graduated series of the benches, and the galleries with the encircling peristyle above—when it existed—would have been as beautiful in general effect, as anything architecture ever produced.

There are varieties in the arrangement of the details of the amphitheatre, as other examples show. Intermediate concentric galleries, platforms, or precincts sometimes intercepted the great bank of graduated benches to serve as passages of communication; and sometimes each staircase communicated directly and exclusively with one vomitory, instead of leading to encircling corridors which communicated generally, and gave access alike to every part of the enclosure.

Next in importance to the Colosseum at Rome, of existing structures of the kind, is the Amphitheatre of Verona. The prefixed vignette will give a tolerable idea of its state of preservation. The great external cincture is entirely gone, with the exception of four arches and their accessories; but the great bank of concentric benches, with the staircases leading to them, and the parts about the arena, remain in a comparatively perfect state. The outer cincture was pierced with seventy-two arches, which number appears in the inner, with the corresponding radiating walls to the traversing passages and staircases,—for this had not a second encircling corridor on the outside of the stairs block as the Colosseum has. The outer dimensions of this structure were 500 feet by 404 feet; the length of its arena is 242 feet, and its breadth or length, on the conjugate, 146 feet; the form, of course, was elliptical.

The amphitheatre at Nismes in Languedoc is large and in comparatively good preservation;—the great external cincture of an amphitheatre remains in a very perfect state at Pola in Istria;—Rome contains the remains of a second amphitheatre called the Castransian;—there are also considerable remains of an amphitheatre at Capua, and of another at Pozzuoli near Naples. That of Pompeii, it has been already remarked, was an extensive structure,—it was in many respects peculiar, but it is not so well preserved as some other examples which have been more exposed, as it suffered considerably from earthquakes before it was buried. At Pæstum, there are indications of an amphitheatre, though not a large one; at Catania, in Sicily, the upper and outer encircling corridor of an extensive amphitheatre is accessible, considerably under the level of the modern city, buried by the torrents of lava from Mount Ætna. Syracuse and several others of the ancient cities of Sicily exhibit remains or indications of small amphitheatres. Indeed, wherever Roman remains are found to any extent, whether at home or abroad, some indication may be almost certainly discovered of the existence at some time of an amphitheatre.

AMPHIUMA, in zoology, a singular genus of batrachian reptiles, first noticed by Dr. Garden in 1771, in a letter to Linnæus. The remarkable and anomalous order of batrachians, to which this genus belongs, are more extensively spread throughout the New World, and exhibit a far greater diversity of organic modification in the western hemisphere, than in all the rest of the earth together. It is here alone that the *menopomæ*, the *amphiumæ*, the *axolotls*, the *menobranchi*, and the *sirens*, are to be found: these singular animals abound in all the lakes and stagnant waters, and astonish the observer equally by the variety as by the novelty of their forms. The most remarkable character of these reptiles is the complete metamorphosis which they undergo in their progress from youth to maturity; a metamorphosis which not only affects their outward form, but entirely changes their systems of circulation and respiration. When first separated from the spawn or egg, they appear in what is called the tadpole form, respiring by means of gills and inhabiting the waters. At this period they have neither legs nor arms, but a long tail compressed sidewise enables them to move about in the manner of fishes. Gradually, however, they acquire legs and feet, and whilst the

formation of these members is in progress, the lungs likewise are developed, in some genera entirely replacing the gills, in others continuing to exist and act simultaneously with these organs throughout the remainder of the animal's life.

[*Amphiuma tridactylum*.]

The external form of the amphiuma is very similar to that of the common eel, but the whole anatomy and physiology of the animal approximates it more nearly to the common water-newt (*Triton marmorata*) than to any other known species. From this creature indeed it differs principally in the extreme length of its body and the diminutive size of its extremities, which rather resemble small tentacles than actual legs. The only two known species inhabit the stagnant pools and ditches in the neighbourhood of New Orleans, and those in Florida, Georgia, and South Carolina. They bury themselves in the mud at the bottom of the ditches, particularly on the approach of winter, and vast numbers of them are sometimes found in draining and clearing ponds, at the depth of three or four feet from the surface. They are also capable of existing on land, but as their food in all probability exists only in the water, they never voluntarily abandon that element. The two known species, *A. didactyla* and *A. tridactyla*, differ principally in the number of their toes, the one having only two, the other three on each foot.

AMPHORA, in its ordinary acceptation, means an earthen vessel, used as a measure for liquids both by the Greeks and Romans. It received its name on account of its two ears or handles. The proper form of the Greek word is *Amphoreus*. It is generally two feet, or two feet and a half in height; and the body, which is usually about six inches in diameter ending upwards with a short neck, taper toward the lower part almost to a point. The Attic amphora contained three Roman urnæ, or seventy-two sextaries, equal to about two gallons, five pints and a half of English wine-measure. The Roman, sometimes called the Italic amphora, contained two urnæ or forty-eight sextaries, about seven gallons, one pint English. Homer mentions amphoræ both of gold and stone; and the Egyptians had them of brass. There are various specimens of earthen amphoræ in the British Museum, in the Elgin and Townley Galleries.

The amphora is still the largest liquid measure used by the Venetians, containing sixteen quarts.

There was another amphora among the Romans, which was a dry-measure, and contained about three bushels.

Earthen amphoræ of the Roman time have been occasionally found in England. Like other domestic vessels of the Romans, they appear to have been sometimes used as funeral urns. Columella says they were used to preserve olives in. When filled with wine, they were usually lined with pitch or some other coating, on account of the porous nature of the material of which they were formed. Amphoræ were placed as urinals in the public streets of Rome till the time of Vespasian.

AMPLITUDE, the angular distance of a celestial body from the east point when it rises, or from the west point when it sets. It depends upon the declination of the star and the latitude of the place, and may be computed from the formula,

$$\sin. \text{amplitude} = \frac{\sin. \text{declination}}{\cos. \text{latitude.}}$$

It must be measured towards the north or south points of the horizon, according as the declination is north or south. For the fixed stars, the amplitude remains the same throughout the year: but for the sun it varies with the declination, being nothing at the equinoxes, and about $39^{\circ} 44'$ of amplitude, in the latitude of London; that is, at the summer solstice, it rises between N.E. by E. and N.E., and sets between N.W. by W. and N.W.; and at the winter solstice, it rises between S.E. by E. and S.E., and sets between S.W. by W. and S.W.

The term amplitude was also applied to what is more commonly called the *range* of a gun; that is, the whole horizontal distance which the gun will carry. It is sometimes also used in the integral calculus.

AMPHILL. [See BEDFORDSHIRE.]

AMPULLARIA is used by zoologists as the name of a genus of fresh-water spiral univalve shells, which inhabits the rivers and ponds of India, Africa, and South America. They are of a globular or rather depressed form, are covered with a thick olive or black *Periostraca*, and often banded. Their mouth is ovate, with the lips complete all round, and often slightly thickened or reflexed. The animals are somewhat similar to the common pond snail, (*Paludina*), but they have the front of the head nicked and furnished with two slight conical horn-like processes, and they have long slender tentacles, with the eyes placed on small pedicels at their outer base; these horns and the tentacles often contract into a spiral form. But the great peculiarity of these animals is, that, unlike all other molluscous animals with comb-like gills, they have a large bag, which opens beneath, placed on the side of the respiratory cavity, which they probably can fill with water; and it is this structure which most likely gives them the power of living for a long time out of water, specimens having been brought from Egypt to Paris alive, by only packing them in a little sawdust. Their operculum is formed of concentric rings with the nucleus nearly in the centre; in the species which come from India, this part is generally shelly, but in those of America and Africa it is always horny. The Indian species lay globular pale green eggs about the size of small peas, which are placed in clusters on sticks and other things in the ditches; the eggs when dry form most beautiful objects. Some of the African species are reversed, or have the whorls of the shell turned from the right to the left, and these have been separated into a genus, under the name of *Lanistes*, on this account. It has been generally supposed by the geologist, that all the species of this genus are purely fresh water, but the large Egyptian species, *A. ovata*, discovered by Olivier in Egypt, lives in lake Mareotis, where the water is salt, therefore there is no proof that some of the fossil species are not marine.

AMPURDAN, a district in Spain in the province of Catalonia, between the river Ter and the town of Rosas. It comprises thirty-two miles in length, and twenty-four in breadth, and is the most fertile part of the province. It produces wheat, barley, Indian corn, and wine. The capital is AMPURIAS.

AMPU'RIAS, a town of Catalonia of some note in ancient times, but now sunk into insignificance. It is situated on an elevated spot near the Gulf of Rosas, $42^{\circ} 7'$ N. lat., and about 3° E. long., fifteen miles east of Gerona, and about seventy miles N.E. of Barcelona. At a very antient period, this town was named Emporium, on account of its extensive trade: a Greek colony from Marseilles settled there, perhaps about the year 545 B.C. Ampurias had antiently a square harbour on the east side of the town, very capacious and secure, part of the wall of which is still visible upon a rock washed by the sea. The port has been obstructed by the great quantity of sand carried down by the rivers Fluvia and Ter, which empty themselves into the sea not far from Ampurias. On the western side of the town, ruins of walls and edifices are still seen, and until the last century, medals, coins, and other relics of its former splendour were found. Under the empire, about the second century of our æra, its decline began, and it is now reduced to forty miserable houses inhabited by poor farmers. In the time of the Goths it was still a place of some consideration, and an episcopal see. Ampurias belongs to the district of Gerona. Castellon de Ampurias, a town not far from it, is frequently mistaken for the same city. (See Strabo, book iii. p. 160 Casaub.; Miñano; Masdeu, *España Griega*.)

AMPUTATION, from *amputo*, to cut off; the opera-

tion of cutting off a limb from the body. Such is the constitution of the animal body in general, and especially of the more perfectly organized body, that if one part of it be diseased, the whole system suffers, while a general disturbance of the system cannot exist long without producing specific disease in some individual organ. Hence constitutional and local diseases are found to exert a most important influence over each other. Some local diseases are of an incurable nature, and proceed progressively from bad to worse. At first, these diseases may not materially affect the general health, but in their progress they produce so much constitutional disturbance, as to endanger life, and ultimately to destroy it. In this case, life is really endangered and destroyed by the local malady; remove that, provided the removal can be effected before the general health is irreparably impaired, and not only is death averted, but health itself is restored. Hence, in all ages, the necessity and advantage have been obvious enough, of removing a part of the body for the sake of preserving the remainder, and men have always been willing to submit to the loss of a limb in order to save the body, on the ground 'that it is better to live with three limbs than to die with four.'

But although it must always have been clear, that it is a gain to save life even at the cost of a limb, when nothing but the removal of the limb can preserve the body, yet it was not always easy to make the sacrifice. Whoever understands the circulation of the blood, and considers the quantity that is sent, and that must necessarily be sent, to each member of the body for its nourishment, and the magnitude of the blood-vessels that are divided in cutting off a limb, will readily perceive how impossible it must have been to perform the operation of amputation before any certain mode was known of stopping the flow of blood from the wounded blood-vessels. But no such mode of stopping hæmorrhage was known to the antients: consequently, though they daily saw the necessity of performing the operation of amputation, yet they looked upon the operation with terror, and shrunk from the responsibility of undertaking it. And no wonder: when they did venture upon it, the consequences were appalling. They cut through the flesh with a red-hot knife, hoping by this means to prevent a fatal loss of blood. After having performed this operation, they dressed the wound with scalding oil, in order to complete what the burning knife may have left imperfect. But these expedients stopped only for a short time the flow of blood. The whole surface of the wound was converted into an eschar, which for a time stopped the bleeding. But the eschar being dead matter it was at length thrown off by the action of the living parts beneath. The moment this took place, the mouths of the blood-vessels were again opened, hæmorrhage took place just as at first; and the patient perished from loss of blood. The uniformity with which this event took place after amputation performed in this mode, could not but cause the operation to be regarded with dismay. Nevertheless, it is pretty clear, that in the time of Celsus, the surgeons of that age were not without some notion of the true mode of stopping hæmorrhage from wounded blood-vessels, for that writer gives particular directions to take hold of the vessels, to tie them in two places, and then to divide the intermediate portion; certain, however, it is, that this practice was not extended to amputation, because nothing was ever amputated by the antients but a part absolutely mortified or dead; and in a part thus mortified or dead, it is not practicable to secure the blood-vessels by the needle and ligature. The general introduction into surgery, of the method of stopping hæmorrhage by taking up the divided blood-vessel with a needle, and placing a ligature around it, must, therefore, be considered as much a modern improvement, as if no allusion whatever had been made to it by antient writers.

But if a knowledge of the mode of stopping hæmorrhage by tying the blood-vessel, be indispensable to the safety of surgical operations in general, the knowledge of some mode of preventing the loss of blood during the actual performance of an operation is indispensable to the safety of the operation of amputation in particular. So large are the trunks of the main blood-vessels that supply the limbs, and so great is the quantity of blood that flows from them in a short space of time, that loss of life is always the consequence of a want of command over these great vessels. By the invention of the instrument termed the tourniquet, an invention of the seventeenth century, (for an account of the construction and application of which instrument, see

ART. TOURNIQUET,) this command is obtained. By these instruments, then, namely, the tourniquet, and the needle and ligature, modern surgeons have such a perfect command over the blood-vessels, that operations may be performed, in which the largest trunks are divided without the loss scarcely of a single drop of blood. On this account, the mere removal of a limb excites in the modern surgeon no degree of anxiety; the operation of amputation is scarcely ever attended with the slightest hazard; nevertheless, there are circumstances connected with amputation of the greatest possible importance, delicacy, and difficulty, on a clear and correct view of which life depends; to obtain such a view, the most extensive knowledge, and the most accurate discrimination, are requisite; while, to act in conformity with it, a high degree of moral courage is often no less necessary. Perhaps the determination of the exact time at which to amputate is sometimes among the most difficult points of surgery; that is, the determination of the time when the preservation of the limb is no longer possible; and when, therefore, it is right to put an immediate stop to any further exhaustion of the health and strength by the removal of the limb. The discrimination of the cases that absolutely require amputation, in contradistinction to those in which the necessity of amputation may be superseded by skilful surgical treatment; the easiest and safest methods of performing the operation; and the best mode of treating the patient after the operation has been performed, involve considerations of the last importance which are often not without considerable difficulty, but these are considerations purely and exclusively professional, and cannot be treated of in a work like the present. No one, however, can look into the modern books which treat of this subject without being struck with the prodigious advancement which surgery has made in recent times; without being deeply impressed with a sense of the debt of gratitude due to the illustrious men who found surgery a mean, and not infrequently a mischievous art, and who have exalted it into a noble and beneficent science.

AMRITSIR, a very antient town, formerly called Chak, the holy capital of the people called Seiks, or Sikhs, in $31^{\circ} 33' N. lat.$, and $74^{\circ} 48' E. long.$ In Burnes' map of the Indus, the latitude and longitude are somewhat more.

It owes its present name to a tank 135 paces square, which was built by the Gooroo Ramdas, who improved the town to such a degree that, for a time, it bore the name of Ramdaspoor. Ramdas died in 1581, and in the course of time the name of Amritsir—the pool of immortality—was transferred from the tank just mentioned to the whole town. This town is without any external walls, its houses are built of bricks and lofty, but the apartments are small and the streets are narrow.

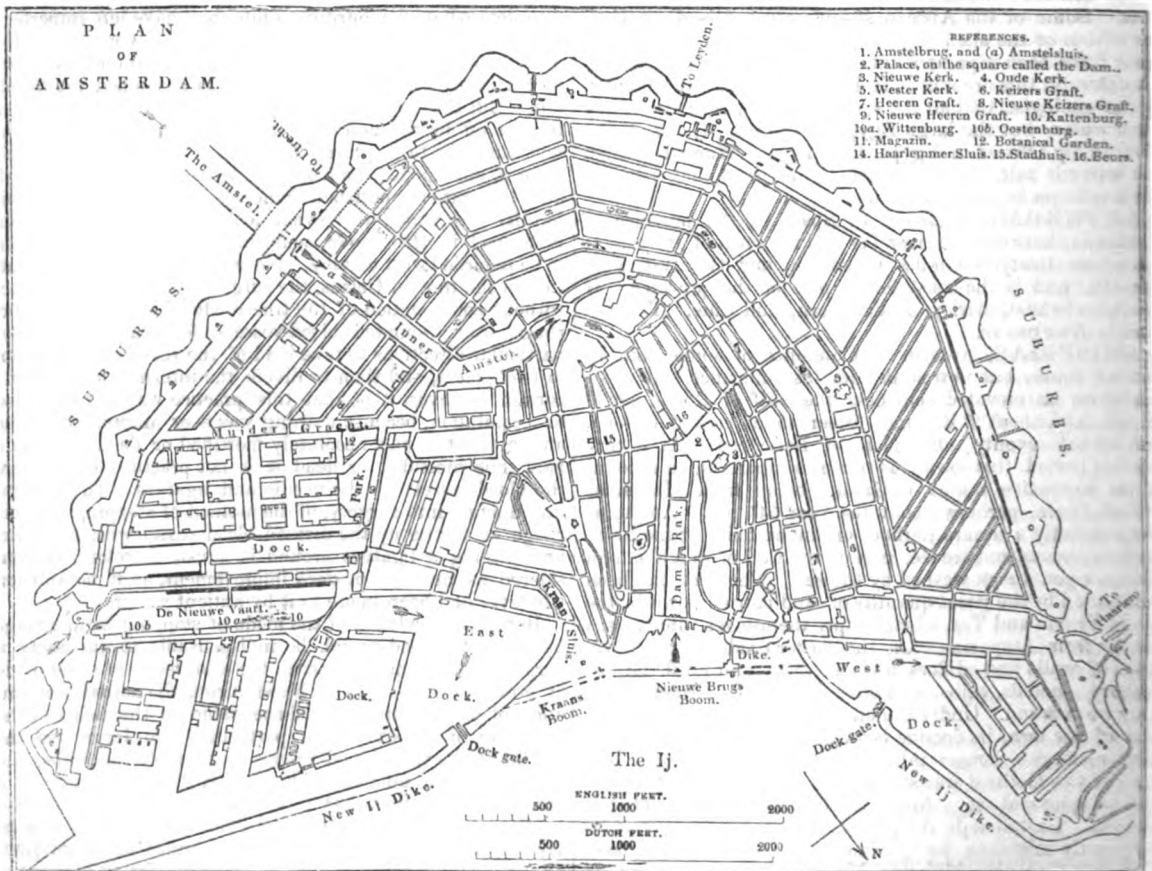

Amritsir has a considerable trade in the shawls and saffron of Cashmere, and is a place of great opulence owing to the resort of merchants and to its being the residence of some bankers of extensive dealings. Its native manufactures are confined to coarse cloths and inferior silk goods. The Rajah Runjeet Singh of Lahore, to whom the district is subject, has lately built a fort here, which he calls Runjeetghur, and he has improved the town by bringing a canal to it from the Ravee, the Hydrates of Arrian.

The sacred pool has a temple in its centre, which is viewed with a high degree of veneration by the inhabitants, and is dedicated to Govind Singh, who died in 1708, and was the last Gooroo, or religious leader of the Sikhs. A book, containing the code of laws, written by Govind Singh, is deposited in this temple, in the service of which upwards of 500 priests are retained.

Amritsir is about 44 miles east from the city of Lahore, which is on the Ravee, and 1312 miles travelling distance north-west from Calcutta.

(Rennell's *Memoir of a Map of Hindostan*; *Manuscript Documents at the India Board*, quoted by Hamilton; *Report of House of Commons on the affairs of the East India Company*, August, 1832.)

AMSTERDAM, the capital of the province of New Holland, and the commercial capital of the Kingdom of Holland, though not the seat of government, stands on the south bank of the Ij, or Y, a gulf of the Zuider Zee, in $52^{\circ} 23' N. lat.$ and $4^{\circ} 54' E. long.$ The small river Amstel runs into the Y through the city, and gives to it the Latinized name of Amstelodamum, and its old name of Amstredamme or Amsteldam; the word *dam*, which so often occurs in the names of Dutch towns, means 'a dyke, or embankment of earth to separate two lakes or canals.' The Amstel, four

miles south of the city, is joined by the Vecht, a branch of the old Rhine which runs past Utrecht. Amsterdam is thirty-two miles north-east of the Hague, and 107 north of Brussels, the capital of Belgium. The city is in the form of a crescent with the two horns projecting into the Y, and forming a kind of port. The Y forms the port of Amsterdam, which was formerly only protected by a double row of piles driven into the ground through the water: the two rows were about seventy feet asunder. About twenty-one openings, called *booms*, were left for ships to pass through, but were carefully closed at night. Large vessels which could not pass through were moored outside in the *laag* or harbour. Between the town and the inner row of piles was the harbour for the small craft. At present two dikes enclose the east and west docks respectively. One begins near the Kraan Sluis and runs eastward, having an entrance called the Dok Sluis; the other commences near the Haarlemmer Sluis and runs westward. (See *Plan of Amsterdam*, 1830, door C. van Baarsel & Zoon.) On the land side it is surrounded by ditches and ramparts, which are now planted, after the Dutch fashion, with trees, and make an agreeable promenade: the *Plantaadje* (place planted with trees) on the south side of the town is the chief place of resort on Sundays and holidays. The approach to this capital on the land side, especially from Haarlem, is described as very striking; the view extends over spacious meadows, covered with luxuriant grass, to the capital, where the tall masts of ships, spires, and houses are all mingled together; and this scene of activity and wealth is in the midst of a marsh, which seems every moment threatened with inundation from the brimfull canals and waters which surround it. But these form the best defence of Amsterdam, and enable the inhabitants to lay the whole country around under water.

Amsterdam was originally a salt marsh, and in order to make a foundation for houses, it was necessary to drive large piles of wood or rather masts through a layer of peat, which in some places is said to be forty or fifty feet thick. The nature of the soil may differ somewhat in different parts; the following facts will show still better its character. In 1605, a well was dug in one of the hospitals of Amsterdam (*Oude Mannen-en vrouwen Gasthuis*) to the depth of 232 Dutch feet. After seven feet of earth, there were found nine feet of peat, and then soft clay, sand, earth, clay rather hard, and earth, altogether making fifty-one feet of depth. Then came ten feet of sand, in which stratum the piles of Amsterdam chiefly rest. At the depth of seventy feet there was found one foot of pieces of peat. Sand, through which they did not make their way, was found at the depth of 232 feet. (See *Tooneel der Vereenigde Nederlanden*, &c. door Halma und Brouer, Leeuwarden, 1725.)

Such is the substructure of a town which now contains above 200,000 inhabitants. The streets are generally in straight lines along the banks of the canals, which intersect the city; among the finest are the Heeren Gragt or Gragt, and the Keizers Gragt, both of which are magnificent streets. Those in the central parts of the town are narrow and without foot-pavement. The private houses are nearly all of brick, painted and ornamented with different colours. The Kalver Straat is filled with shops for jewellery, porcelain, China, books, pictures, and other articles of luxury, and though narrow, this defect is compensated by the rich display of merchandize. Several of the streets are lined with fine rows of elms, walnut trees, and limes. The canals within the town, or *grachten*, as the Dutch call them, are so numerous that the city is divided into ninety islands, which communicate by 290 bridges: the Amstel itself divides the town into the eastern or old, and western or new part, and is crossed by a bridge, the Amstel-Brug, partly built of brick and partly of stone, with thirty-five arches; it is about 610 English feet long, sixty-four and a half wide, and furnished with iron balustrades. Through the eleven central arches large ships pass. Near the bridge is the great sluice, (*Amstelsluis*), by which the waters of the river can be either dammed out, or allowed to flow through the city. By shutting the gates the course of the Amstel is stopped, and the country round the city laid under water.

Amsterdam contains thirteen churches for the reformed religion, one English Presbyterian, one English Episcopal, one of the Remonstrants, three Lutheran, two Anabaptist, one of the United Brethren, sixteen Catholic, one Armenian, one Greek, five Jansenist, one Portuguese and one German Synagogue, in all forty-seven places of worship, or one for

every 4255 persons. The number of charitable institutions is considerable.

This city has twelve public places, but not one of them is either large or magnificent: the *bogt* (bend) of the Heerengracht is a kind of circus which contains some of the best houses in Amsterdam. In the Dam we see the *Stadhuis*, or old town-hall of Amsterdam, built of Bremen and Bentheim stone, and said to rest on 13,659 piles of wood (*Halma*): it is 282 feet long, 235 deep, and 116 high, and crowned with a tower. The interior is adorned with a profusion of marble, statues, and pictures, which attest the splendor of the Amsterdam merchant, when he erected this edifice in 1648, during the glorious days of the republic. The marble hall is, perhaps, the finest room in Europe, being 120 feet long, 56 feet broad, and 98 feet high. Louis Buonaparte, who had a great liking for palaces, contrived to get possession of this when he was King of Holland, and the present royal family retain it as a palace. The *Beurs*, or exchange, is a large old building with nothing remarkable, except the concourse of merchants from all countries.

The church of St. Nicholas or the Old Church, (*Oude Kerk*), is of great antiquity, but its precise date is unknown. In 1578 the Reformed service was first performed in it. The length of the church with the tower is about 278 feet; the tower itself is 221½ feet high: the width of the church at the transepts, measured on the inside, 207½, and on the outside 192 feet. This church contains the tombs and monuments of many of the great warriors and seamen of Holland: among them is the monument of Admiral Heemskirk.

The New Church (*Nieuwe Kerk*) was originally built, partly on the model of the cathedral of Amiens, but being burnt down in 1645, it was speedily rebuilt, and is, in the opinion of the Dutch, one of the handsomest churches in Europe. Its pulpit is a curious specimen of carving; and the great organ is also much admired. It is 350 feet long, says a Dutch description, 210 wide at the transepts; the upper part rests on 52 pillars of hard stone, and the church is lighted by 75 large windows. It is also conspicuous for its noble and incomparable bronze (or brass?) ornaments of the quire, which consist of six quadrangular fluted columns, and fourteen other small pillars, with two great doors, adorned with two lions holding the arms of the city, and surrounded with well-executed leaf-work: all this, weighing many thousand pounds, rests on a noble marble base. This bronze work, which from top to bottom is 30 feet high, is cleaned twice a-year.

In the high quire of this church is the marble monument of the great Dutch admiral De Ruyter. In another part of this church is erected a monument to the hero Van Speyk.

The Admiralty buildings, the dock-yard, the extensive magazines, on Kattenburg, and even the model-room are accessible to strangers. Near the dock-yard is a marine school, called the *Kweek-School*, or seminary, for the instruction of youths in naval tactics. The warehouses and quays of the East and West India Companies, though they are very considerable, will not excite the wonder of any person who has visited the banks of the Thames.

Among the many literary establishments of Amsterdam we must mention the academy on the Keizergragt, a large and tolerably handsome building, whose title is indicated by the words *FELIX MERITIS*, in large gilt letters, under the pediment. This academy is divided into five sections, which embrace the various departments of science and learning. There is also an observatory. The *Doctrina et Amicitia* is another learned society, which has a library, museum, and news-room in the Kalver Straat. The botanical garden is not extensive, but contains some old specimens of Cape plants.

Among the places of amusement are three theatres. Among the prisons, the *Rasphuis*, where the criminals used to saw various foreign woods, and the *Spinhuis* (spinning-house) for females, are best known.

The commerce of Amsterdam was founded by the industry and perseverance of its inhabitants, to which the institution of the bank in 1609 has materially contributed. This is one of the oldest establishments of the kind in Europe, and has always been conducted with the utmost regularity and good faith. Amsterdam is a great depôt both for the commodities of the East and West Indies, with which it carries on a great trade through the Dutch colonies and its own trading companies.

The approach to Amsterdam from the North Sea or

German Ocean is through the passage formed by the Texel and the extreme point of North Holland into the Zuider Zee, the navigation of which is difficult: near the entrance is a bar called the Pampus, over which ships are taken by means of large vessels or boxes, called camels, which being passed under the ship, and then exhausted of their water, buoy the whole up several feet. But since the completion in 1825, of the great **HEIDER CANAL**, (54 English miles long,) Amsterdam has at all seasons a safe and easy communication with the Texel by means of an inland navigation through the whole length of North Holland. By means of its canals Amsterdam has an easy water communication with Utrecht and the Rhine, with Haarlem, the Haag, Leyden, Delft, and Rotterdam. One steam-boat is employed during summer in conveying passengers to Hamburg, and two smaller ones as ferry-boats across the Zuider Zee. Amsterdam has no water that is fit to drink or suitable for culinary purposes, but what is brought in boats from the Vecht, a distance of fifteen miles: the pure water of Utrecht is sold in the streets for table use and for making tea and coffee. The want of so indispensable a necessity must be unfavourable to health, and the stench that arises from the canals in the hot days of summer is sometimes almost intolerable. The fuel of this great city is chiefly turf, which is found in great abundance in most parts of the kingdom. Billets of wood are occasionally used, and coals from Newcastle or the Forth by those who can afford to pay for them. It is remarked that Amsterdam has changed so little for the last century, that the guides and descriptions of this city, published a century ago, may still be considered as correct and useful companions. The origin of Amsterdam is traced to a small fishing place, established on the Amstel, probably during the twelfth century; but the date has not been ascertained by Dutch antiquaries; the name Amsterdam first occurs in a letter of Count Floris, A.D. 1275, in which he exempts the town of Amstelredamme from certain tolls or taxes. In 1482 it was walled, and from 1578, when the states of Zeeland and Holland united with Brabant, Flanders, &c., in the pacification of Ghent, it began to acquire that commercial superiority which Antwerp had hitherto possessed; and of which its various sufferings tended to deprive it. When the Schelde was closed in 1648, the commerce of Amsterdam increased still more at the expence of Antwerp. The area on which the town stands has of course been extended at different periods, but, as far as we can learn, not since 1658.

The chief articles of import are West and East India produce, tobacco, hides, rice, linseed, and grain: the value of imports of the chief articles into Amsterdam by sea was,—in 1829, 2,107,852*l.*; 1830, 1,864,891*l.*; 1831, 1,904,261*l.* The chief exports to Great Britain are cheese, oil-cake, oak-bark, and grain.

In 1827, 1887 ships entered the port of Amsterdam.

The number of vessels that cleared at Amsterdam was, in 1829, 1975; in 1830, 1996; in 1831, 1624. Those to Great Britain were respectively in the three years, 82,114, and 209.

The manufactures of Amsterdam are considerable: the principal are the bleaching of wax and linen cloth, the manufacturing of tobacco, leather, silk, sugar, calico-printing, cotton-spinning, diamond cutting, cannon foundry, and ship-building.

Population of Amsterdam in 1814 . 180,000

1820 . 195,000

1829 . 201,000

January 1st, 1830 . 202,364

Of this number, 202,364, there were 90,332 males, and 112,032 females.

	Males.	Females.	Total.
Deaths in Amsterdam in 1829 .	4056	3942	= 7998
Births "	3785	3618	= 7403

In this year there were 25 deaths of persons above the age of 90, of whom 17 were females.

Büsching states the number of houses in Amsterdam, in 1732, at 26,835, which, we suspect, is more than the present number, and adds that the population was supposed not to exceed 200,000. The burials from 1747 to 1752, a period of six years, averaged 8247 each year.

The lowest ranges of the thermometer noted at Amsterdam are,

1798 . 30th December . 2 Fahrenheit.

1823 . 21st January . 4 "

1830 . 2d February . 1 "

AMSTERDAM, a small island in the Indian Ocean, discovered in 1697, by Van Vlaming, a Dutch navigator, and situated in 34° 42' S. lat., and 76° 51' E. long.

This island is about four miles and a quarter long from north to south, and two and a quarter from east to west; but so much of its area is occupied by a basin or harbour, that its surface does not contain more than between seven and eight square miles of land. The basin, here mentioned, was formerly a large volcano, into the eastern side of which the sea has forced a passage by the action of its waves, which roll with an uninterrupted current from the east.

The width of the breach thus made is 1000 feet, but the part of the opening through which the tide flows is only one-fifth of that width. The original form of the crater was that of an ellipse, its largest diameter being 3000 feet, and its smallest 2550 feet; it had thus a circumference of nearly a mile and three-quarters, and as its sides rise to the height of 700 feet, at an angle of 65° with the horizon, the brim of the basin has a circuit of rather more than two miles: it must therefore have been one of the largest kind of craters. The depth of water in the centre of the basin is 174 feet, which, added to the height of the sides above the water, gives 874 feet for its entire depth.

The coast in every other part is inaccessible, and exhibits everywhere successive streams of lava. To the north of the entrance of the harbour, and a short distance from it, is an insulated rock, of a pyramidal form, which rises out of the sea to the height of between 200 and 300 feet. This rock is composed of forty or fifty horizontal layers of lava, piled regularly one upon the other. The face of these layers is cracked and divided by perpendicular fissures, many of which are filled with veins of obsidian or volcanic glass, and the same appearance is visible several feet below the surface of the sea. In other of the fissures are some curious specimens of zeolite. Signs of fusion are evident on every part of the surface of this rock, which seen from a short distance has the appearance of scoria from an iron furnace. Obsidian and pumice-stone abound on all the coast.

The slanting sides of the crater contain many thermal springs, some of which run freely, while others ooze out in the form of mud. The temperature of these springs is various, some being 196° of Fahrenheit, and others at the boiling heat; the temperature of the surrounding atmosphere when these temperatures were taken being 62°. Swamps and stagnant pools of water, varying in their heat from 80° to 130°, are found on every part of the island. Most of the springs are brackish; one of them, the temperature of which is 112°, is strongly chalybeate.

The soil is altogether volcanic; it is spongy and porous, and trembles under the feet. If the ear be applied to the surface, a sound like that of bubbling water may be heard.

The sea on the coast abounds with fish. Among these are some red-coloured perch, from six to twelve inches in length; another species of perch from three to four feet long; rock-cod and bream. The quantity of cray-fish seen crawling on the bar, at the entrance of the crater at low water, is almost incredible; and they are so plentiful in the open sea, that if a basket baited with flesh be lowered to some depth for a few minutes, it will be found half filled with cray-fish when drawn up.

No frutescent plant is found on the island. The list of its vegetables is confined to mosses, and other genera of the cryptogamous class, with a few kinds of grasses. Not a single quadruped of any kind inhabits the island, which is likewise free from all insects, with the exception of the common fly. Land birds are never seen here, but the number of aquatic birds which resort hither to lay their eggs is astonishing. Among these are the white and the brown albatross; crested penguin; black, grey, blue, and stormy petrel; puffin; silver bird, or sea-swallow; and a small brown duck, not larger than a thrush.

The shore of Amsterdam island is resorted to by great numbers of seals, for which reason this speck in the ocean, nearly 2000 miles distant from any land, except the little island of St. Paul, is visited by the Americans, who carry the skins which they there procure, to China.

A paper in the twentieth volume of the *Philosophical Transactions*, which gives an account of the discovery of this island by Van Vlaming, states, that the sea was then so crowded by seals and sea-lions, 'that it was necessary to kill them in order to effect a passage for the ship to the shore.' These animals, although still abundant, are certainly

not now in sufficient numbers to obstruct the passage. Another marvellous statement in the same paper was to the effect, that fish might be caught in the sea with one hand and cooked with the other, in the natural boiling springs, and this assertion has certainly been corroborated by Mr. Barrow, who, in 1793, dropped some perch 'living, off the hooks into a boiling spring, and found them cooked to perfection in fifteen minutes.'

Amsterdam island is about midway between Australia and Madagascar.—(*Philosophical Transactions*, vol. xx.; Barrow's *Voyage to Cochinchina*.)

AMSTERDAM, NEW. [See *BERBICE*.]

AMU. [See *Oxus*.]

AMULET, in barbarous Latin, *Amuletum*, or *Amoletum*. Some suppose the word to be of Arabic origin. An amulet hung round the neck, or carried in any other way about the person, is absurdly believed to have the effect of warding off morbid infections and other dangers, and even of curing diseases by which the body has been already attacked. The belief in the efficacy of amulets has subsisted at some time among almost every people, and the thing has been denoted by a great variety of names, which it is unnecessary here to enumerate. The phylacteries, or bits of parchment with passages from the Bible written upon them, which the Jews were wont to carry about with them, were amulets; of just the same character are those inscribed with sentences from the Koran, which the Moorish priests sell to the negroes of Africa, and to which the latter give the name of *Fetishes*. This superstition, which existed also among the Greeks and Romans, appears to have in early times prevailed extensively among the converts to Christianity, if we may judge by the denunciations directed against it by St. Chrysostom, and others of the fathers. But even down to our own day, it has continued to be an article of the popular creed, that certain medical preparations, and other things, merely carried about the person, have the power both of repelling and of healing diseases. Even the celebrated Robert Boyle adopts this notion, assuring us that he once experienced the efficacy of such an amulet in his own case. 'Having been one summer,' he says, 'frequently subject to bleed at the nose, and reduced to employ several remedies to check that distemper; that which I found the most effectual to stanch the blood was some moss of a dead man's skull, (sent for a present out of Ireland, where it is far less rare than in most other countries,) though it did but touch my skin till the herb was a little warmed by it.' (*Essay of the Porousness of Animal Bodies*. See also his *Essays on the Usefulness of Natural Philosophy*, and his *Experimental Discourse on some Unheeded Causes of the Insalubrity and Salubrity of the Air*.) The anodyne necklace, which consists of beads formed from the roots of white bryony, and is sometimes hung around the necks of infants with the view of assisting their teething, is an instance of the still surviving confidence in the medical virtue of amulets. Such also is the belief generally entertained by seafaring people, that a child's caul on board their ship will preserve them from being lost—and many other examples might be easily quoted.

AMUR, one of the largest rivers of Asia. If we except the two largest rivers of Siberia, (Oby and Lena,) and those of China, (Hoang-ho and Yantse-kiang,) only the Irawaddy, in the Burmese empire, is superior to it in the length of its course. The sources of the Amur are situated near 110°, and its mouth about 143° E. long. The mouth is opposite the northern extremity of the island of Taraikai, formerly called Saghalien, in 53° N. lat.

This river carries off nearly all the waters of the slopes and the mountains in which the great Asiatic desert, Gobi or Shamo, terminates towards the east; and it would be advantageous to geographical science if we were well acquainted with the country which it traverses. But as only a comparatively very small tract of country along its sources belongs to the Russian empire, and all the remainder of its course is subject to the Chinese, who do not admit European travellers into their territories, our knowledge of this part of the globe is very deficient.

The true source of the Amur is the river Onon, which rises near the 110th meridian, in 50° N. lat., in that range of the King-gan Oöla which is called *Kentei-Khan*. This river, which waters a country at present nearly uninhabited, is famous in Mongol history, the great hero, *Tshingis-khan*, was born, and distinguished himself in his youth, on its banks. The Onon first runs from west to

east for about 160 miles, and afterwards to the north-east for about 320 miles, till it joins the Ingoda. The latter river rises on the eastern declivity of the Tshokondo, the highest summit of the range, which separates the tributaries of the Amur from those of the lake of Baikal, or of the Yablonoi Krevet; and runs nearly parallel to the Onon till it joins it, after a course of about 160 miles. After this junction the river is called Shilka by the Russians, and Saghalien-Ula by the Mandshoo, and continues under this name its north-eastern course for about 260 miles, when it meets the Argun or Erguné, a large river, which in its upper course is called Kherlon, and has its sources also in the Kentei-Khan, near the 110th meridian, but about three degrees farther to the south, in 47° N. lat. The Kherlon runs, according to the Chinese geography, in the first part of its course, to the north for about seventy miles, then for about thirty-five miles to the south-east, and afterwards to the north-east for 320 miles. It then changes the direction of its course to the east, making its way through two ranges of high mountains, and after having run in this direction for about a hundred miles, it falls into the large lake of Kulun or Dalai Nor, whose circumference is considered by the Chinese to be about 600 *li*, or nearly 210 miles. From this lake the river issues under the name of Argun, forms the boundary between the Chinese and Russian empire, and, after a north-north-eastern and northern course of about 400 miles, joins the Shilka, in 53° 23' N. lat.

After this junction the river is called Amur by the Russians, who adopted this name from the Ghileaki, a tribe of the Tunguses, living near its mouth, in whose language Amur or Yamur signifies the great river, or the great water. The Mandshoo preserve the name of Saghalien-Ula (river of Black Water).

The Amur does not long continue its north-eastern course. An extensive mountain-range, the King-gan Yalo, stretching from south to north, obliges the river to take the same direction. But it soon forces its way through the mountains, forming for perhaps a hundred miles a succession of rapids till it enters the plain situated to the east of the mountain-range. The rapids formed in this extensive tract do not seem to render the river unnavigable, though at present it is not used.

During its passage through the mountains, the Amur changes the direction of its course from north to east, declines afterwards to the south-east and south, and continues in this direction till, from the 54th parallel, it has descended to the 48th. It then resumes its eastern course, and at its most southern point, (47½° lat.,) its waters are increased by those of the Sungari or Songari Ula, which by the Chinese is considered as the principal river. The Songari Ula rises nearly under the 42d parallel in a mountain-mass called Tshang-pe Shan, (the White Mountain or Mount Blanc, on account of the snow with which its summit is always covered,) which extends along the northern coast of the Hoang-hai, (Yellow Sea,) and forms the northern boundary of the peninsula of Corea. Its general course lies N.N.W. till it joins the Naun or Nonni Ula, a large river which descends along the eastern side of the King-gan Yalo mountains, from the 52d parallel to the 46th in an opposite direction from north-west to south-east. After this junction the Songari-Ula runs E.N.E. till it joins the Amur.

At a considerable distance from the junction with the Songari Ula, the Amur again changes its course, running henceforth to the N.N.E. up to its embouchure, and traversing the country between the meridians of 125 and 140, and between the parallels of 47 and 53. In this part of its course it receives another considerable river, the Usuri-Ula, which runs parallel to the Pacific Ocean, from which it is divided by a high mountain-range; but this tributary of the Amur is entirely unknown.

The whole course of the Amur, from the sources of the Onon to its mouth, amounts, perhaps, to nearly 2000 miles, owing to the great and frequent changes of its direction; in a straight line, the sources and mouth are only about 1330 miles distant from one another.

As far as this river is known it abounds in fish, but though they are the same species as those of the rivers in Europe, they are, as Pallas observes, distinguished by some peculiarities. The most common are two kinds of carp, (*Cyprinus leptcephalus*, Pall., *Cyprinus labio*, Pall.) barbels, and a smaller kind of shad-fish (*Sturus asotus*). The beluga, a larger kind of sturgeon, is frequently caught in the Shilka, but the common sturgeon is rare, as well as a kind of trout

(*Salmo oxyrhynchus*). Craw-fish, which are not found in the north of Asia, are very frequent in all the tributaries of the Onon and Shilka, but they are smaller and smoother than those in Europe. The common pike is yellow like gold and spotted like the fish in India: Pallas, at the first view, was inclined to consider them as a distinct species. Pearl-oysters are found in the Onon and some of its tributaries, and the common barnacle in some lakes attains an extraordinary size and thickness. Pallas got some which were upwards of a foot long, and from three to four-tenths of an inch thick.

The country watered by this river and its branches is divided by the King-gan Yalo mountains into two parts, quite different in their character; this mountain range is to be considered as the eastern boundary of the great desert of Gobi or Shamo, and the country to the west of it, about the Onon and Argun, preserves many of the characteristics of the desert. It is considerably elevated above the level of the sea, but as yet the elevation of no part of it has been exactly determined. To this elevation it must chiefly be attributed, that the Shilka and the Argun, both of which are slow rivers, are commonly covered with ice from five to six months in the year, though they flow under the parallels of London and Paris. The air, like that of the great desert, is very dry. Rain in summer and snow in winter are far from being abundant. The greatest part of the soil, perhaps more than nine tenths, is sandy and sterile, and unfit for agricultural purposes, and of the remainder a small portion only is actually cultivated: but in that part of this region which belongs to the Russian empire, and which may amount to nearly one-third, agriculture was much more attended to before the Cossacks conquered it. On their arrival here, in the middle of the seventeenth century, they found very large tracts cultivated with care, but the cruelties and vexations exercised by them obliged a whole nation, the Da-üres, from which this country is called Da-uria, to abandon their native soil and to take refuge within the Chinese empire.

The country to the east of the King-gan Yalo, which belongs altogether to the Chinese empire, exhibits an entirely different appearance. Though the mountains which separate the valleys along the Amur, Songari-Ula, and Na-un-Ula, rise to great height, the valleys seem not to be greatly elevated above the level of the sea. This is indicated by a much milder climate, by the frequency of large forests of oak, lime-trees, and hazel-nut trees, which replace the scanty woods of fir and larch of Da-uria, as well as by the abundance of a kind of cherry-tree. The ground along the river, and even to a certain height on the slopes of the mountains, is cultivated, and produces barley, rye, wheat, buck-wheat, and hemp, and between the fields extend fine meadows. Since the accession of the present dynasty to the throne of China, many persons are banished to these valleys for their crimes or misdemeanors; and this policy, it is said, contributes powerfully to improve the state of agriculture. The valley of the Usuri, however, seems to be more elevated, and is therefore chiefly inhabited by a branch of the Mandshoo, who still follow a pastoral life. The mountains which divide this valley from that of the Songari-Ula produce a plant, which is regarded as a great treasure, the *ginseng*, which in China is considered a panacea; this is the only place where it is found on the old continent. [See GINSENG.]

Not far from the banks of the Shilka, and on those of a small river called the Nertsha, the Russians have built the town of Nertshinsk, which, according to Captain Cochrane, does not contain more than 1000 inhabitants. The principal town in the Chinese territories is Kirin or Girin-Ula on the Songari-Ula, the seat of a provincial government. In the valley of the Na-un-Ula is the town of Naun-Koten, and in that of the Usuri, Ninguta, the native place and patrimony of the Mandshoo dynasty at present reigning in China.

The Russian part of Da-uria has been abandoned by all the native nations, except a small number of Tunguses who still wander about with their herds. In the Chinese territories some aborigines are still found. [See MANDSHOORIA.] (*Travels of Pallas and Timkowsky; Ritter's Erdkunde von Asien.*)

AMURATH. [See MURAD.]

AMYGDALÆÆ, a natural order of plants belonging to the division of polypetalous dicotyledons, among which it is known by its bearing the kind of fruit called a drupe, by the

stamens being numerous and arising from the orifice of a tubular calyx, and by the leaves yielding the fluid called prussic acid. Owing to the last circumstance, the species are all more or less poisonous, especially in those parts where the prussic acid is concentrated, as the leaves of the common laurel, the skin of the kernel of the almond, &c. On the other hand, those parts in which the prussic acid exists either in very minute quantity, or not at all, as the succulent fruit, and sometimes the kernel, are harmless, and are often valuable articles of food. It is on this account that, while the general character of the foliage is either unwholesome or suspicious, the fruit of many of them is much cultivated. The peach, the nectarine, the plum, the cherry, the almond, the apricot, prune, damson, and bullace are produced by different species of this order.

[Amygdaleæ.]
1. An expanded flower. 2. The same with the corolla removed.
3. The same cut through. 4. Anthers. 5. Drupe.
6. Stone. 7. Embryo.

Besides the substance already mentioned, the bark of amygdaleæ yields a gum which is similar in its properties to gum arabic; and an astringent substance which gives some of the species so much efficacy in fevers, that their bark has been compared for utility to that of Peru; and even in some cases, as the coccimiglia bark of Calabria, the produce of *prunus coccimilia*, has been preferred.

AMYGDALOID, the name of a variety of the trap rocks, when in a uniform base there are imbedded round or almond-shaped bodies, consisting of agate, calcareous spar, or zeolites, like almonds in a cake; the term is derived from the Greek *ἀμυγδαλοειδής*, resembling an almond.

AMYGDALUS, the genus from which the order derives its name, comprehends the almond, and the peach and nectarine, besides a few bushes, the chief interest of which arises from their gay appearance.

A. communis, the common almond, is a native of Barbary, whence it had not been transferred into Italy in the time of Cato; it has, however, been so long cultivated all over the south of Europe and the temperate parts of Asia as to have become, as it were, naturalized in the whole of the Old World from Madrid to Canton. In this country, it is only grown for the sake of its beautiful vernal flowers; but in the countries that have a long and hot summer, it is the fruit for which it is esteemed. This, which is produced in immense quantities, is partly exported into northern countries, and partly pressed for oil, or consumed for various domestic purposes. Although botanists distinguish only one species of eatable almond, yet there are many varieties, of which the principal are the bitter and the sweet; of each of which the French and Italians have several sub-varieties distinguished by the hardness or softness of their shell, and the form or size of the kernel. These have all been introduced into England, but none of them are capable of ripening their fruit in the neighbourhood of London, except in unusually fine hot summers, preceded by mild and uninterrupted springs.

A. Persica, the peach, once called the Persian apple, because it was introduced from that country into Europe, has, for ages, been an object of careful cultivation for the sake of its delicious fruit, and has almost naturalized itself even in the New World. In our gardens many varieties are known, which are classed under the two heads of peaches and nectarines according as their fruit is smooth or downy: of the varieties there are few that are not worthy of cultivation, but the best are, perhaps, the red magdalen, noblesse, and royal George peaches, and the Smith's Newington, or tawny nectarine. For a late crop of peaches, the *têton de Venus* may be recommended: but not the Catherine, nor indeed any of the thick skinned October peaches, which, however excellent in the south of Europe, seldom ripen, and never acquire the

natural flavour in this country. For preserving, the blood red, or sanguine peach, the flesh of which is of the deepest crimson, is worth a place in a garden.

For the mode of cultivating the peach and nectarine, see *TEACH*.

AMYOT, JAKUES, great almoner of France, bishop of Auxerre, commander of the order of the Holy Ghost, rose to these high dignities and to wealth from the humblest rank in life. He was a native of Melun (1514), chief town of the department of *Seine et Marne*, about thirty miles from Paris. His father was a butcher or a currier, it has not been ascertained which, but in very limited circumstances. When he came to Paris to continue his studies, he was obliged to act as servant to some of his fellow students, in order to procure the means of subsistence, the only weekly allowance which he received from his friends being a loaf of bread. After studying under the learned professors of the college of France, which had then been recently founded, and after taking his degree of master of arts, at the early age of nineteen, he went to Bourges to study law; there he distinguished himself so much as to induce the king's lecturer, Jacques Colin, to intrust him with the education of his nephews. Subsequently, through the patronage of Marguerite de Valois, sister of Francis I., Amyot obtained a Greek and Latin chair at the University of Bourges. Whilst he was filling that situation, he undertook a translation of Plutarch's Lives, of which he dedicated the first books to the king, Henri II. The monarch, as a mark of his approbation, gave him the abbey of Bello-sane, and desired him, at the same time, to continue a work so replete with merit. This circumstance gave him an opportunity of displaying talents of another kind; for, under the pretence of going to Italy to consult some manuscripts, he was entrusted with a letter from Henry the Second to the council of Trent, then assembled. Although he was not invested with any public character or authority, he displayed nevertheless much firmness and adroitness in his mission; so great, in fact, was the satisfaction which the Cardinal of Tournon felt on this occasion, that he recommended him to Henry II. as a fit person to be the tutor of his three younger sons. Charles IX., on his coming to the throne of France, made Amyot his great almoner and keeper of the University of Paris; soon after he gave him the vacant see of Auxerre. It is said that, at the death of Charles IX., and on the day his funeral took place at St. Denis, the Parliament of Paris sent for Amyot, that he might say grace for them, acting as king of France. We should here observe that Henri III., the brother and successor of Charles, was yet in Poland; the Parliament might, therefore, suppose themselves to be reigning in his absence: besides, there was then a party who wished to put the crown on the head of the Duc d'Anjou, second brother of the late king Charles, the same who had been on the eve of marrying Elizabeth of England, and to refuse it to the king of Poland. Amyot disobeyed the command, and hid himself. Henri III., on his accession to the throne, continued him in his dignities, and moreover made him commander of the order of the Holy Ghost. Amyot had much to suffer from the league to which he was thought to be an enemy; he was even accused of having been privy to, and having participated in, the assassination of the Duc de Guise, at Blois (December, 1588). So inveterate were the leaguers against him, that they attacked and plundered him some time after as he was returning to Auxerre; nor, indeed, could he appease this hostile spirit until he had obtained a formal absolution from the Pope's nuncio, of the crime of participation of which he was suspected. He was, however, afterwards allowed to finish his days in quietness, in his diocese, where he died in 1593.

As a literary man, Amyot stands high; no one did more service to French letters. His translation of Plutarch's Lives, which was made from the Latin, is spirited and elegant; and it is remarkable that the best translation of Plutarch in English, North's, is made from Amyot's French. His other works consist of French translations of other Greek works, of which the principal are, *The Æthiopic History* of Heliodorus, seven books of Diodorus, the *Pastoral Loves* of Daphnis and Chloe, &c. He has, besides, given an Account of his Journey to Trent, in a letter addressed to M. de Morvilliers. He composed a treaty on royal eloquence for the use of his pupil, Henri III., which was printed, for the first time only, in 1805, under the reign of Napoleon. It was at the suggestion of Amyot that Henri III. founded, in 1575 a Greek and Latin library.

Amyot has been accused of avarice: this charge is, however, partly refuted by the fact of his having spent large sums for the repairs and embellishments of the churches of his diocese. He left the sum of 700,000 francs at his death, although he frequently complained of his having been ruined by the league.

AMYRIDÆÆ, a natural order of plants consisting of tropical trees, the leaves, bark, and fruit of which abound in fragrant resin. It is known among polypetalous dicotyledonous orders by its hypogynous stamens, which are twice as numerous as the petals, by the large disk in which the ovary is inserted, and by its one-seeded, fleshy fruit, covered all over with resinous glands.

The odoriferous substances called gum elemi, bdellium, and resin of Coumia are all produced by different species of amyridææ.

ANA, a Latin termination of the neuter plural form. It appears in our language, divested of the sign of gender, number, and case, in such words as subterranean, metropolitan, Christian, Anglican, Ciceronian, Johnsonian. The Latin *ana* is the form appropriated to the neuter plural; and, therefore, *Ciceroniana*, for instance, would signify, matters, or things of any sort, about, or appertaining to Cicero.

In modern times this termination has been used to denote collections, either of remarks made by celebrated individuals in conversation, or of extracts from their note books, letters, or even published works, or, generally, of particulars respecting them.

Such collections have been made in all ages, and in every country in which literature has been cultivated. For an enumeration of ancient works, still existing or known to have once existed, of a similar character to the modern *ana*, the reader may consult Christopher Wolf's preface to the *Casuboniana*, and the *Introductio in Notitiam Rei Litterariæ* of B. G. Struvius, with the notes of J. C. Fischer, Frankfurt, 1754, chap. viii., sections 11, 12, 13, and 14. These writers mention as coming under this description the Proverbs of Solomon, those collections of the sayings of the wise which are to be found in many oriental languages, those which the disciples of Pythagoras and of other ancient philosophers are stated to have made of the remarks that fell from their masters, the *Απομνημονεύματα*, or *Memorabilia*, of Socrates recorded by Xenophon, the sayings of Epictetus, said to have been collected by Arrian in the four last books (now lost) of his *Commentary on the Enchiridion*, and in his twelve books of *Homilies*, the *Deipnosophistæ* of Athenæus, the Biographies of Plutarch and Diogenes Laertius, the *Facetiæ* attributed to Hierocles, the several collections of Stobæus, the *Meditations* of Marcus Antoninus, the books of apophthegms by Cæsar, mentioned in Cicero's *Letters*, the jests and bons mots of Cicero, said to have been collected by his freedman Tyro, the *Natural History* of Pliny, the *Noctes Atticæ* of Aulus Gellius, &c. The catalogue, it must be confessed, is constructed upon sufficiently liberal principles; but a good many of the performances which it comprehends might certainly have been called *Ana* in the modern sense.

A curious approach to an anticipation of the modern use of the word occurs in a letter of Francesco Barbaro to Poggio Bracciolini, in which, alluding to some literary anecdotes which Poggio and his friend Bartolomeo Montepulciano had collected in Germany, and were bringing home with them, he says, that as certain sorts of apples and pears are called *Appiana* and *Malliana* from having been first introduced by persons of the names of Appius and Mallius, so these importations of theirs will be afterwards called *Poggiana* and *Montepolitiana*. The letter is dated in 1417. It is given in Lefant's *Poggiana*, at the end of the second volume, where it was first printed entire. But it does not appear to have been till after the middle of the seventeenth century that the exact modern application of such epithets came into fashion. In 1659 we find Guy Patin, in one of his curious gossiping letters, speaking of having in his possession certain manuscript Borboniana, Grotiana, and Naudæana, meaning collections of anecdotes respecting Nicolas Bourbon (the younger), Grotius, and Gabriel Naudé. Very soon after this appeared the first printed *Ana*.

This was the collection of the colloquial remarks of Joseph Scaliger, now distinguished as the *Scaligerana Secunda*. Two brothers, Jean and Nicholas de Vassan, the sons of a M. Vassan, Sieur de Remi-Mesnil, and whose mother was a sister of the eminent scholars Peter and Francis

Pithou, having gone to study at Leyden, carried with him letters of recommendation from Casaubon to Scaliger, who was then one of the professors in that university. In consequence they were much at his house, and heard a great deal of his conversation, both in company and in private. Such of his observations upon all sorts of subjects as they considered to be most valuable or remarkable they wrote down, till the collection at last formed a thick octavo volume. On their return to France they gave their manuscript to the learned brothers Claude, Pierre, and Jacques Du Puy; and the latter lent it to M. Sarran, who took a copy of it which came into the possession of his son, Isaac Sarran. From him it passed into the hands of Hadrian Daillé, a French protestant clergyman, and a man of letters, who gave the book a new form by arranging the remarks according to the alphabetical order of their subjects. From Daillé Isaac Vossius, in the course of a visit which he made to Paris, procured the manuscript, but, as it appears, without any notion on the part of the lender that he would make any other than a private use of it. Having, however, got it home with him to Holland, he transcribed it, and some time after sent his copy to the press. The book was published in 1666, with the title of *Scaligeriana, sive Excerpta ex ore Josephi Scaligeri*: per FF. PP., (contraction for *Frates Puteanos*.) This impression, however, so abounded in inaccuracies, that Daillé, notwithstanding his regret that the publication had taken place at all, felt himself called upon to give to the world a new and more correct edition, which appeared accordingly the following year, with the title of *Scaligerana; editio altera, ad verum exemplar restituta, et innumeris usque fœdissimis mendis, quibus prior illa passim scatebat, diligentissime purgata*. There is some uncertainty as to where these volumes were published. That of Vossius (which, however, does not bear his name) is a 16mo. volume of 368 pages, in rather a large type, and, in the only copies which we have seen, is stated to have been printed at Geneva, by Peter Cumesius. All the accounts also, as far as we know, state that it bore this impress, though actually printed by Vlacq, at the Hague. But it is certain that Daillé, in the advertisement prefixed to his own edition, speaks of it as actually announcing itself on its title-page to have been published at the Hague; 'Hagæ-comitum (si titulus vera fert)' are his words. Daillé's edition, again, which is a 12mo. of 268 pages, but in so much smaller a type as to contain a good deal more matter than the other, professes to be printed at Cologne, by Gerbrandus Scagen. But it is said to have been really printed at Rouen. It is very incorrectly printed, and has a long list of errata prefixed: but, besides being considerably more full, it is purified from many gross blunders, which make the edition published by Vossius frequently unintelligible. In his preface address (to which however he does not put his name), Daillé complains in indignant terms of the publication at the Hague, which he says had taken place not only without the consent of those to whom the manuscript belonged, but in opposition to their most strenuous remonstrances and menaces. He also corrects the title, which, in the original, he says, is *Scaligerana*, not *Scaligeriana*. The word *excerpta* he thinks must be a printer's blunder for *excepta*. He likewise gives the true history of the manuscript, and refutes the assertion of the Hague edition, that its contents had been taken down from the lips of Scaliger by the Du Puits. It would appear, however, that Vossius, or his publisher, paid no attention to any of these corrections; for a new impression, in all respects the same with the first, was published by Vlacq at the Hague, in 1668. Some of the copies of this edition bear the impress of Leyden; but they are said to differ in nothing else from the others.

It happened, however, that the Vassans were not the only persons by whom Scaliger's conversations had been noted down. Before they knew him, and, indeed, while he lived in Touraine, and before he went to Leyden, a physician of the name of François Vertunien, who attended the family of the MM. Chateigners de la Rochepozai, in whose house Scaliger resided, had been in the habit for seventeen years, namely from 1575 to 1592, of keeping a record of the remarks that dropt from the lips of the great scholar. Vertunien's papers remained for a long time after his death almost unknown, till they were at length purchased from a person into whose hands they had fallen by M. de Sigogne, an advocate of the parliament of Poitiers. By him they were committed for publication to the care of Tanneguy le Fèvre, (better known by his Latinized name of Tanaquillus

Faber;) and they accordingly appeared along with the former in 1669, bearing the following title, *Prima Scaligerana, nusquam antehac edita, cum Prefatione T. Fabri; quibus adjuncta et altera Scaligerana, quam antea emendatiora, cum notis ejusdem V. D. anonymi*. The volume is a 12mo., and the new matter fills 150 pages in a large type; that which had been printed before filling 257 in a much smaller type. Throughout both, the notes are intermixed with the text. It bears to be printed at Groningen by Peter Smithæus; but is understood to have been actually printed at Saumur. In the copy of this edition in the British Museum, which appears to be perfect, there is no preface, although one is announced in the title-page: but in a subsequent edition, bearing to be printed at Utrecht by Peter Elzevir, in 1670, there is a strange address, made up principally of bursts of Greek and Latin verse, entitled, *Ad Aeliam Borellum Prefatio*, and having Le Fèvre's name subscribed, in which the writer says, that he has determined not to publish the promised preface, having, after he had begun to write it, been induced to desist by certain considerations which he does not choose to specify. It would, he intimates, have contained some things not generally known. The *Scaligerana Prima* are all, or nearly all, in Latin; the *Secunda*, partly in Latin and partly in French. They were afterwards mixed together and arranged under one alphabet; being first published in this form, we believe, at Cologne in 1695, in a 12mo. of 418 pages, with the title, *Scaligerana, ou Bons Mots, Rencontres Agréables, et Remarques Judicieuses, de J. Scaliger, avec des Notes de M. le Fèvre et de M. de Colomiers*. Such is an outline of the leading particulars, which have not always been correctly stated, of this curious portion of literary history. A German author, John Theodore Leubsch, published a short dissertation in 4to., at Wittenberg, in 1695, entitled *Historia Scaligeranorum*; and the subject is examined at greater length by Des Maizeaux, in his edition of the *Scaligerana, &c.*, in two vols., Amsterdam, 1740. As in all other collections of this kind, both the *Scaligerana* contain many things which it may be very much doubted if the person to whom they are attributed ever uttered. Any deficiency either of competency, of care, or of fidelity in the reporter, must of course have left its proportionate produce of error or misrepresentation. But even if we could be certain that the report had been given with the most perfect accuracy, it would be unfair to regard statements and opinions, thus delivered in unpremeditated conversation, as affording a true measure either of the judgment, or the information of the speaker. They may convey to us an idea of the general style and spirit of his manner of talking, and in that way give us some insight into his character; but that is almost their only value. As elucidations of the subjects treated of, they are commonly worth very little. The publication of the *Scaligerana*, accordingly, did not add to the reputation of Joseph Scaliger. The multifarious learning for which he had been celebrated was discovered to have been pretty frequently at fault in these extemporaneous displays: and having all the arrogance, with but little of the genius of his father, he was thought in most of his sallies, to have given more evidence of a bad temper than of a brilliant wit. The indecency and licentiousness of some of his jests, also, equalled their dulness.

The next of the *ANA* which appeared was the *Perroniana*, being notes (in French) of the conversations of Cardinal du Perron. It appeared in 1669, in a 16mo. volume of 332 pages, with the following title: *Perroniana, sive Excerpta ex ore Cardinalis Perronii*: Per FF. PP.; and, like the first published *Scaligerana*, which it closely resembled in all respects, bore the impress of P. Cumesius, at Geneva. It is believed, however, to have been printed at the Hague, and there is no doubt that this book also was sent to the press by Isaac Vossius, who had obtained it from Daillé in the same manner as he had the *Scaligerana*. These notes had been taken down by Christophe du Puy, or Puteanus, the elder brother of Claude, Pierre, and Jacques, already mentioned; their manuscript had been copied by Claude Sarran in 1642; and from this copy Daillé had made another transcript in 1663, arranging the remarks in alphabetical order. Menage, we may remark, in his *Anti-Bailet*, Part i. chap. 80, says that the edition given by Vossius was actually published at Rouen. However this may be, in the same year, and with a similar title-page, the same person gave to the world another of these collections, the

Thuana, or remarks of the President de Thou. This he had also obtained from Daillé, to whom, like the others, they had come through Sarrau, the notes having been originally taken by one of the Du Puys, but which of the brothers is uncertain. Daillé was as much dissatisfied with the editions published by Vossius of the *Perroniana* and *Thuana*, as he had been with that of the *Schægerana*; and he caused both to be reprinted the same year at Rouen, as is believed, although the title-page says at Cologne. Both of these *Ana* contain some curious articles, the *Perroniana* particularly; but mixed with what is valuable, are many other things which very little deserved to be recorded; and upon the whole, neither collection can be said to come up to the expectation naturally raised by its title.

As publications, however, these works had extraordinary success; and the avidity with which they were read, produced a long succession of similar productions. It was in France, or at least in the French language, that most of the *Ana* appeared; and their popularity may be said to have lasted for fully half a century. In a history of French literature, therefore, an account of these collections would form an important chapter. In this place we must confine our further notice of them to little more than an enumeration of those that are best known.

One of the most valuable of this class of publications, is the *Menagiana*, a record of the conversations of Menage, who was a man of distinguished wit and talent, as well as a great scholar. He died in 1692, and the following year the *Menagiana* appeared in a 12mo. volume, both at Paris and Amsterdam. The persons by whom the materials were supplied, and the expense of the publication defrayed, were his friends Galland, Boivin, Dubos, Pinson, and De Valois. The same year was published a satire upon the work and the individual whom it commemorated, under the title of *Anti-Menagiana*—the production of a physician of Blois, of the name of Jean Bernier, whose pen, however, was not a very sharp one. A second volume of the *Menagiana* appeared in 1694; the materials of which were principally contributed by the Abbé Faydit; and two years after, a new addition of the whole was published at Amsterdam. The original edition, however, contains several things which were suppressed in those that followed. The book was republished at Paris, in 1715, by Bernard de la Monnoye, accompanied with such copious annotations as increased it to four volumes; and in the following year a new edition of the same size appeared at Amsterdam, in which De la Monnoye's additions were separated from the original, and placed in the two concluding volumes by themselves. This is the form in which the *Menagiana* has since been printed. Bayle passes a high eulogium in his dictionary upon the *Menagiana*, describing it as a nobler monument erected to the glory of Menage, than all the works published by himself, learned and able as they generally were. Upon the whole, indeed, this is perhaps the best of the *Ana*.

Another collection of considerable value is the *Chevræana*, which was published by Urbain Chevreau himself, in two volumes, 12mo., at Paris, in 1697, and again at Amsterdam, in 1700. Along with this may be mentioned the *Purrrhasiana*, or *Remarks and Opinions of Theodore Purrrhase*, under which title the well-known critic, John le Clerc, published, at Amsterdam, in 1699 and 1701, two volumes of his own lucubrations. In keeping with the name he assumed, which was intended to mean the frank speaker, the *Purrrhasiana* contained a formal defence of several of his own works, in which he spoke of them in a manner that would have come with more grace from any other of their admirers than from the author himself. Another of the collections bearing this title, which does not consist of conversations reported by others, but of observations recorded by the individual himself, is the *Huetiana*, or thoughts on different subjects, of the celebrated Bishop of Avranches, which was published from his papers at Paris, in 1722, the year after his death, by the Abbé Joseph Thoulrier d'Olivet: but, although this collection contains several elaborate and instructive articles, still, deliberately prepared as it was, it partakes, in great part, of the frivolity of the class to which it belongs. It would appear that persons writing under this title conceived they had a licence to trifle. The *Casauboniana*, also, which Christopher Wolf published at Hamburg, in 1710, were transcribed by him from Isaac Casaubon's own note-book, or *Ephemerides*, as he had entitled it, which had been bequeathed to the Bodleian library by his

son Meric. This collection, too, has had the common fate, and has been considered to contain little or nothing worthy of the fame of the great scholar.

Some of the *Ana* are understood to be little better than forgeries throughout. Such, for example, is the character of the collection entitled *Naudæana et Patiniana*, or *Remarkable Singularities noted down from the Conversation of Gabriel Naudé and Guy Patin*, which was first published at Paris, in 1701. In so far, at least, as Naudé is concerned, the jests which are recorded in this work are probably about as authentic as those recounted in the hawkers' pamphlet, so popular in Scotland, professing to be a collection of the sayings of George Buchanan, which, had it been compiled in France, indeed, might possibly have received the title of *Buchananiana*, and under that pompous designation have held a very different literary rank from what it can at present lay claim to. The *Sant-Evremoniana*, first published at Amsterdam, in 1702, is believed to be, for the most part, another of these impositions. This collection is singular, as having been published during the life-time of the person from whom it takes its name. St. Evremond lived till the following year, when he died at London, at the age of 92. He denied the authenticity of this work a short time before it made its appearance, by a letter published in the *Ephemerides Parisiennes*. Its author, or compiler, was a person of the name of Charles Cotelendi,—from whom is also believed to have proceeded a burlesque production, of little talent, entitled *Arlequiniana*, first published at Paris, in 1694.

Of the remaining *Ana*, some of the most famous are the *Poggiana*, or the *Life, Character, Sentences, and Bons Mots of Poggio (Bracciolini) the Florentine*, published at Amsterdam, in 1720, in two volumes, 8vo., by James Lenfant, a protestant minister, who (although the work contained little that had not been before in print) was thought to have somewhat disregarded the decencies of his profession, in giving a new impression of so licentious a miscellany: the *Furetieriana*, or *Bons Mots of Antoine Furetière*, (author of the *Dictionnaire Universel de la Langue Française*), published by the Sieur Guy-Maraïs, in 1696; the *Vulesiana*, or *Thoughts of Adrien de Valois*, the Royal Historiographer, published by his son, in 1695; the *Pithæana*, or *Conversations of Francis Pithou*, which had been collected by his nephew, and which M. Teissier printed from a copy made by M. La Croze, in the third volume of his additions to the *Éloges* extracted from the writings of M. de Thou, Berlin, 1704; and the *Segraisiana*, or *Opinions of the poet Jean Renaud de Segrais*, which were taken down by a person placed behind the tapestry in a house which he frequented. This book was published both at Paris and Amsterdam, in 1722, about twenty years after the death of Segrais. So many persons still alive, however, were injuriously mentioned, or alluded to, in the book, that it was suppressed at Paris almost as soon as it appeared. It is extremely questionable for how much of its malice Segrais is really responsible. Voltaire has characterised it as being of all the *Anas* the one that best deserves to be set down in the list of printed lies, and, above all, of lies in which there is no wit. But Segrais was a man of true talent, as Voltaire himself, in his *Age of Louis XIV.*, has testified.

There are also the *Rabutiniana*, the *Santoliana*, the *Conringiana*, the *Launoiana*, the *Varillasiana*, the *Borboniana*, the *Chevaneana*, the *Sorberiana*, the *Sevigniana*, the *Longueruana*, the *Bolæana*, the *Carpentarianiana*, the *Ducatiana*, &c. To these may be added a few German productions, such as the *Taubmanniana*, the *Wigandiana*, the *Schurtzleischiana*, the *Gundlingiana*. Of our English *Ana*, by far the most celebrated is the *Walpoliana*, being a collection of the conversational remarks of Horace Walpole, together with a good many fragments copied from his papers, which was first given soon after his death in portions in the *Monthly Magazine*, and then published, with large additions, in a separate form. Both in curious information and liveliness of manner, the *Walpoliana* may be favorably compared with the best French publications of the same class. Our other English *Anas*, such as the *Addisoniana*, the *Johnsoniana*, the *Swiftiana*, the *Mooriana*, are, most of them, merely collections of anecdotes taken from the common biographies of the persons to whom they refer, or of extracts from their works.

There are various publications, also, both in French and English, which might seem, from their titles, to belong to the class of *Ana*, but which are really of quite a different description. It may be sufficient merely to name a few of

these, such as, the *Caribbeana*, containing *Letters and Dissertations*, chiefly wrote by several hands in the *West Indies*, 2 vols., 4to., London, 1741; the *Joineriana*, or the *Book of Scraps*, (by Samuel Patterson,) 2 vols., 8vo., London, 1772; the *Anonimiana*, or *Miscellanies of Poetry, Eloquence, and Erudition*, 12mo., Paris, 1700; the *Gasconiana*, a collection of bons mots of the Gascons, by M. de Montfort, Amsterdam, 1708; the *Pantalo-Phebeana*, a satire on Fontenelle and others, the production of a M. Bel, a counsellor of the Parliament of Bourdeaux; the *Panagiana Panurgica*, a critique by M. de Premonval, or the book entitled *Les Mœurs*, which was written by François Vincent Toussaint, &c.

On the other hand, there are many works, which, without bearing the characteristic title of such collections, belong in all other respects to the class of the *Ana*. We have already enumerated several productions of the antients, which are of this description. One of the earliest and most celebrated of such works in modern times is the *Colloquia*, or *Table-Talk* of Luther, first published in German at Eisleben, in 1565, and afterwards in Latin at Francfort, in 1571. There is an English translation of this work, by Captain Henry Bell, published in 1652. Another is the *Locorum Communium Collectanea ex Lectionibus D. Philippi Melancthonis*, published in 1562, by John Manlius. There is also a volume, however, published at Altdorf, in 1771, by G. T. Strobel, with the title of *Melancthoniana*. Another very celebrated work of this kind is the *Table-Talk of John Selden*, which is stated to have been collected by Richard Milward, and was first published in 1689. But although this work is commonly reckoned among the *Ana*, it is hardly of the same class with most of those that have been so designated, containing as it does little or nothing that is anecdotal, and consisting almost entirely of maxims which have no special reference to the person by whom they are said to have been uttered. It has been said that there was in existence another *Seldeniana*, or *Collection of the Conversations of Selden*, in French, being a translation from an English original entirely different from the *Table-Talk*. This is mentioned in a curious book entitled *Mélanges d'Histoire et de Littérature, recueillis par De Vigneul-Marville*, first published at Rouen in 1699, which has itself been commonly reckoned among the *Ana*, and is one of the most valuable of that class of publications. It is, indeed, often referred to under the title of the *Marrilliana*. Its author was Noel Bonaventure d'Argonne; but in the latest editions it has been extended to three volumes, the last of which is an addition to the original work, by the Abbé Banier. Under this head we may also mention the *Mélanges Historiques* of Paul Colomiès, first published in 1675, and since repeatedly printed under the title of *Colomesiana*. And we might add to the list, probably, several scores of works in both our own and other languages, which are in like manner *ana* in every thing except in their titles. Boswell's *Life of Johnson*, for instance, is undoubtedly the most remarkable work of this description in existence.

Mr. Southey has published a little work in two volumes with the title of *Omniana*, being a collection of detached remarks on a variety of subjects; but the same title had been previously adopted in a French publication, of which, however, we know nothing more than that it is called *Omniana, ou Extrait des Archives de la Société Universelle des Gobe-mouches*, par C. A. Moucheron, son premier aide-de-camp, 12mo., Paris, 1808. It would appear to be a burlesque production.

One of the volumes of the great French work, the *Encyclopédie Méthodique*, bears the title of *Encyclopediana*, and professes to be a collection of every thing that is most curious and valuable in the different publications of this class. The remarks and anecdotes are arranged in alphabetical order; but there is no reference in general to the sources from which they have been obtained. The following works, apparently of a similar description, had also appeared before this; *Elite des Bons Mots, &c., principalement des Livres en Ana*, 2 vols., 12mo., Amst., 1707; and *Nouvelle Bibliothèque de Littérature, d'Histoire, &c., ou Choix des meilleurs Morceaux tirés des Ana*, (par Guillaume Grivel,) 2 vols., 12mo., Lille et Paris, 1765. We have in English, *Selections from the French Anas*, translated, 2 vols., 12mo., Oxford, 1797. No complete collection of the *Anas* has ever been printed; but there are several partial collections. One of the best of these is the *Scaligerana, Thuana, Perromiana, Pithæana, et Colomesiana, avec Notes par Pierre Des Mai-*

zeaux, 2 vols., 12mo., Amst., 1740. Another larger collection, but without notes, was printed in 10 vols., 8vo., at Amsterdam in 1799, with the title of *Ana; ou Collection de Bons Mots, Contes, Pensées détachées, &c., des Hommes célèbres, tirées de différens Recueils*. This is a complete reprint, with short prefaces attached to each work, of the *Furetieriana*, the *Poggiana*, the *Menagiana*, the *Marrilliana*, the *Carpentarianiana*, the *Valensiana*, the *Huetiana*, (to which is added the *Lettre par Huet sur l'Origine des Romains*), the *Chevræana*, the *Sevigniana*, and the *Bolæana*.

The most complete list of these publications which has appeared, is that given by Peignot in his *Repertoire des Bibliographies Speciales, Curieuses, et Instructives*, 8vo., Paris, 1810, in which 109 titles ending in *ana* are enumerated. This writer absurdly conceives the termination in question to be a corruption or contraction of the word *anecdota*, the title *Menagiana*, for instance, being, he says, when written properly and at full length, *Menagianecdota*. For further information on the subject of the *Ana*, the reader may consult the preface, by Wolf, to the *Casauboniana*, 12mo., Hamburg, 1710; the *Nouveaux Mémoires d'Histoire, de Critique, et de Littérature*, par M. l'Abbé d'Argigny, 8vo., Paris, 1749, tom. i. pp. 287, &c., and tom. vii. pp. 1, &c.; B. G. Struvii *Introductio in Notitiam Rei Literariæ*, cura Jo. Ch. Fischeri, 8vo., Franc., 1754, pp. 752-763; *Morhofii Polyhistor*, lib. i. cap. xvi.; *Gott. Stollii Introductio in Historiam Litterariam*, per C. H. Langium, 4to., Jenæ, 1728, pp. 54, &c.; and various other authorities referred to by Peignot. There is a well known little poem by La Monnoye, in which he enumerates the names of the most celebrated *Ana*, published and unpublished, concluding with the couplet,

Messieurs, nul de tous ces ana
Ne vaut l'Ypécacuanha.

The verses may be found in his collected poems, and also in his edition of the *Menagiana*. In something of the same spirit, Voltaire has said of these collections, that we are indebted for them for the most part to those bookmakers who live on the follies of the dead.

ANABAPTISTS, a religious sect. The word, composed of two Greek terms, properly signifies those who baptize a second time, or insist upon the necessity of a second baptism in persons whom they admit to their communion. It is sometimes applied to designate that large body of Christians in our own and other Protestant countries, one of whose articles of belief is, that baptism ought only to be administered to adults, and who, accordingly, rebaptize those who seek to join them. But this application of the name is quite unwarranted, and one against which the community in question have always protested. They do not maintain the necessity of a new or second baptism, nor are those who have been born and brought up in their persuasion ever baptized twice. Others, who may have been previously baptized in infancy, are, indeed, baptized once again when they have grown up; but this is done on the principle that the former ceremony was no baptism at all. *Baptists* is the designation assumed by those who thus hold the doctrines of the non-validity of infant, and the necessity of adult baptism; and they will accordingly be properly noticed under that head.

We are not aware, indeed, that there has ever been a sect which maintained the necessity of two successive baptisms. On the other hand it is certain, that there were various sects in the earlier ages of the church which agreed with the modern Baptists in allowing no validity except to adult baptism. But the epithet Anabaptists appears to have been first employed to describe a body of fanatics who made their appearance in Germany soon after the commencement of the Reformation; and although it has been since frequently applied to other religious bodies as being alleged to have sprung from these, such a use of it can only be considered as one of those imputations with which different sects have been in the habit of assailing each other.

The Anabaptists were, no doubt, the growth of the Reformation—though Protestant writers have laboured hard to make it appear that such was not the case. They were the ultra-radicals of the Reformation. Munzer, Stubner, and Storck, who were the first heads and apostles of the sect, had all been disciples of Luther; although no person could have more earnestly condemned their proceedings, than did that great reformer. They first began to preach their peculiar doctrines in the town of Wittenberg, in Saxony, in the year 1521. In 1526, their followers, composed almost

exclusively of the lowest rabble, rose in a general rebellion against the established authorities throughout that province, Suabia, Thuringia, and Franconia. But this insurrection, which it is but fair to remark was partly of a political character, and occasioned by the oppression to which the peasantry were subjected, was soon defeated; and Munzer himself, being taken, was put to death. The novel notions, however, which he had preached, spread as usual under persecution; and, some years afterwards, the mischief broke out again with new fury. In 1532, a numerous mob of these fanatics, conducted by John Matthias, a baker, of Haerlem, and John Boccoldt, a tailor, of Leyden, suddenly attacked the city of Münster during the night, and made themselves masters of the place. Their adherents immediately flocked thither from all quarters; and elated by their success, the congregated enthusiasts are stated to have given themselves up to extravagances far exceeding anything they had before practised. Matthias named Münster Mount Zion, and proclaimed himself its king. Having madly undertaken, however, attended with only thirty followers, to attack and disperse the forces which came to recover the town, he perished, with all who accompanied him. John of Leyden now assumed the royal dignity, and under his conduct the multitude is said to have proceeded to wilder excesses than ever. The city, however, was at length recaptured by the army which the Bishop had brought up against it, on the 24th of June, 1535; and Boccoldt, having fallen into the hands of the victors, was soon after executed with the most terrific cruelties that hatred and revenge could dictate.

The most extravagant tenets, as well as conduct, have been commonly ascribed to the Anabaptists of Münster; but the accounts of a proscribed sect by their enemies, it is to be remembered, are scarcely to be received with implicit credit. The doctrine which gave occasion to their distinctive appellation was one of the least remarkable of all their peculiar articles of belief, although they are said to have inculcated it with singular emphasis and vehemence, being in the habit of declaring that infant baptism was an invention of the devil. A much more pernicious principle which they are accused of having held, at least in so far as the peace of society was concerned, was that of the unwarrantableness of all civil government, and the emancipation of the faithful from subjection to either laws or taxes. They are also said to have maintained that, among the saints, all things ought to be in common. Their speculative theology is described as having been much the same with that which has been, and still is, patronised by various other denominations of enthusiasts. It rested principally on the notion that God made his will known to them individually by special inspirations, by way of enhancing the importance of which they are said to have expressed themselves with some degree almost of contempt or disparagement of the written word. Besides the internal impressions which they called inspirations, they had dreams and visions in which they put much confidence; and some of them conceived themselves to have the gift of prophecy, which they were especially accustomed to exercise in predicting the speedy approach of the end of the world. Akin to these delusions was another favourite and fundamental dogma, that every true believer attained even in this life perfect freedom from sin. This position soon led them a great way. Finding that what had commonly been called sin could not be altogether extirpated from the bosoms even of the stoutest believers, they found it necessary, in order to save the doctrine, to declare that certain things which had hitherto been deemed contrary to the divine law, were not so at all, but in reality either indifferent or meritorious. It does not appear that they are accused of having gone quite to the extreme to which the principle in question has sometimes led, of maintaining generally that the belief of the sinner sanctified or neutralized his sin, or, in other words, that an act which would have been sinful in another became divested of its sinful character when committed by a believer. If all that is stated of them be true, indeed, they were under no necessity to resort to this device in order to give a loose to their inclinations, having put down in their list of universally permissible indulgences most of those things to which there is any violent disposition in the multitude of mankind. They condemned, for instance, with great severity, all ornamental attire, and some even went the length of objecting to clothing altogether. Boccoldt himself, in one of his fits of exaltation, solemnly promenaded the streets of Münster, stark naked. The love of dress, they said, was an

artificial vanity, and as such hateful to God. But whatever, on the other hand, they held to be natural, they looked upon as harmless or commendable. Boccoldt is stated to have urged upon his followers, as in the highest degree conducive to their spiritual welfare, the practice of a liberal polygamy, and to have illustrated and enforced his doctrine by taking to himself no fewer than fourteen wives.

For a long time after the events which have been related, it was dangerous in Germany and other parts of the continent to profess an adherence to the doctrine of adult baptism, those who held that tenet being all most absurdly classed as belonging to the sect of the Anabaptists of Münster. It has been commonly said that to avoid the persecution to which they were subjected, the remains of these fanatics in course of time adopted various new denominations, some congregations calling themselves Mennonites, after an eminent leader of the sect, others Waterlandians, from the place of their principal church, others Baptists, &c. But there is really no proof that any of the communities bearing these names had, in their origin, any connexion whatever with the Münster insurgents. They were merely confounded with these madmen in consequence of holding the doctrine of the invalidity of infant baptism, which the Münster Anabaptists were also said to have preached. This accidental coincidence, indeed, was ground of identification enough for the genius of persecution in a former age, as it continues to be for that of intolerance and calumny in the present. But such misrepresentation is really not more reasonable than it would be for Roman Catholic writers, as some of them have done, to describe the Protestants generally as followers of the principles of John of Leyden, because they all, in common with him, reject the authority of the Pope; or for the Jews to bring a similar charge against the whole body of believers in Christianity. For further information on the subject of the Münster Anabaptists, the reader may be directed to Mosheim's *Ecclesiastical History*, section iii., part ii., chapter iii., where he will find the subject treated with great learning, though not in a spirit of much liberality or candour. The principal works relating to the Anabaptists are all referred to in that dissertation.

ANABASIS, the title of a Greek work, in seven books, by Xenophon of Athens, which describes the circumstances of an expedition undertaken by the younger Cyrus, B.C. 401, against his brother Artaxerxes, King of Persia. The expedition is remarkable as being the first long march of which we possess a detailed account, and also the oldest extant document which gave to Europeans any tolerably precise notion of the countries watered by the Upper Tigris and Euphrates.

The army of Cyrus contained a large body of Greek mercenaries, among whom Xenophon, at first, held no military rank: he went apparently as a mere spectator, and only took command after the death of most of the generals. Cyrus set out from Sardes (now Sart) 38° 34' N. lat. 28° E. long., and marched through Asia Minor to the passes in Mount Taurus that lead into Cilicia. He next passed through Tarsus, along the Gulf of Scanderoon, and through the north part of Syria to the Euphrates, which he crossed at Thapsacus, about 35° 14' N. lat. He then marched S.E. through Mesopotamia, crossing the Araxes (the Khabour); and finally lost his life in an engagement with his brother on the plains of Cunaxa, (the site of which is unknown,) about forty miles from Babylon, (now Hillah,) 32° 28' N. lat. 44° 14' E. long.

From this point commenced the retreat, commonly known as the Retreat of the Ten Thousand. Instead of returning by the way which they came, it was determined to reach some of the Greek colonies on the Black Sea. Accordingly they crossed the Tigris; and advancing along the east bank of this river up the stream, they crossed in succession the Diala, and other tributaries of the Tigris. They followed the course of this river, till they were stopped about 37° 20' N. lat., by the mountains pressing close on the river, and allowing no passage along its banks. They then crossed the mountains, and advanced probably nearly due north, but their course from this point is very uncertain. It is probable that the army passed to the west of Lake Van, and in its progress it must have crossed the Morad or Eastern Euphrates, and that branch of the Araxes which is now the Faz, and is called by Xenophon the Phasis. After enduring much hardship from snow, want of food and clothing, and the opposition of the native tribes, the army at last reached Trapezus, now Trebisond, on the Black Sea, in 41° 2' N. lat. 39° 28' E. long. From Tra-

pezus the army marched along the coast westwards for about 100 miles (direct distance) to Cotyora.

The narrative of Xenophon contains a statement of the army's marches, with some few omissions, expressed in Persian parasangs, at the rate of thirty stadia to a parasang. The following are the distances given by him in round numbers:—

From Ephesus to Cunaxa	Stadia. 16,050
From Cunaxa to Cotyora (eight months)	18,600
	34,650

Xenophon adds the march of the Greek auxiliaries from Ephesus to Sardes (about 50 miles) to the distance from Sardes to Cunaxa.

The march may be considered as having terminated at Cotyora, as the army sailed from this place to Sinope, now Sinub: their troubles, however, continued till they reached Byzantium, now Constantinople, and even beyond that point.

If we take the stadia of Xenophon at the rate of ten to a mile, an estimate which is above the truth, we find the whole distance marched to be 3465 English miles, which was accomplished in fifteen months, and a large part of it through an unknown mountainous and hostile country and in an inclement season. The reader will find the expedition of the younger Cyrus discussed in the work of Major Rennel, and the various difficulties that occur in the narrative of Xenophon explained, as far as means of information will allow, with the Major's usual good sense and sagacity. [See XENOPHON.]

Anabasis is also the name given by Arrian, who was in all things an imitator of Xenophon, to his work in seven books, in which he describes the campaigns of Alexander the Great. [See ARRIAN.]

ANACARDIA'CEÆ, or the CASHEW tribe, is a natural order of plants, consisting exclusively of woody plants, abounding in an acrid resin, which is easily discovered by bruising the leaves, but which is not indicated by its being collected in transparent receptacles in the leaves, as is most commonly the case. They are polypetalous dicotyledons, with perigynous stamens, a simple, one-seeded, superior fruit, and alternate leaves without stipulæ.

(*Anacardium occidentale*.)
1. Male flower. 2. Hermaphrodite do.
3. Back of do. 4. Fruit.
5. Section of do. All slightly magnified.

Their juice is often used as a kind of varnish, for which it is well adapted in consequence of its turning hard and black when dry. It is, however, often dangerous to use, because of the extreme acridity of the fumes, which are apt to produce severe inflammation in many constitutions.

The best-known genera of the order are, in the first place, *rhus*, or the sumach, so many species of which are cultivated in our gardens; and the *pistacias*, the nuts of which are served at desserts, and their juice is commonly sold in the shops under the name of mastich and Scio turpentine. Besides these, there are the Chilian *duvaues*, which resemble myrtles, the *mango*, the fruit of which is so delicious in tropical countries, and the *Cashew*, or *Acajou nut*. *anacardium*, from which the order takes its name.

The last, *Anacardium occidentale*, is a small tree found

[*Anacardium occidentale*.]

all over the West Indies, where it is much cultivated for the sake of its bunches of fragrant rosy flowers, as well as of its fruit. Its stem, if wounded, yields abundantly a milk, which, when inspissated, becomes intensely black and hard: besides which, it secretes a gum not inferior to gum arabic. The nut is a kidney-shaped body, seated on a large fleshy protuberance resembling a peach, or an apple, and being in fact, the extremely dilated disk or receptacle; the latter is sometimes red, sometimes white, and is employed by the West Indians in various ways. The nuts contain, in abundance, beneath the outer shell, the black caustic oil of the order, which, when volatilized by heat, as happens in the process of roasting, is apt to produce erysipelas and other disagreeable affections in the face of persons standing over the fumes; the kernel is a well-known wholesome article of food. In the West Indies it is used as an ingredient in puddings, is eaten raw, and is roasted for the purpose of mixing with Madeira wine, to which it is thought to communicate a peculiar agreeable flavour. In this country, the Cashew nut never flowers, and can only be cultivated as a tender stove plant.

ANACHARSIS THE YOUNGER. [See BARTHELEMY.]

AN'ACREON, one of the most famous lyric poets of Greece. Little is known of his personal history. He was born at Teos, a city of Ionia, in Asia Minor, and was probably of obscure birth, since the name of his father has not been ascertained, and four persons are mentioned by Suidas, to whom that honour has been ascribed. Madame Dacier, on the other hand, has endeavoured to prove that he was a relation of Solon and Pisistratus, and a descendant of Codrus, and thus connected with the noblest blood of Athens; but it has been shown by Bayle, that the passage of Plato, on which she founds this assertion (Charmides. 157, ed. Steph.; p. 54. Priestley), cannot be made to bear such a meaning. The exact periods of his birth and death are unknown; but he began to be distinguished in the 35th Olymp. B.C. 559, about the beginning of the reign of Cyrus, and he came to Athens in the reign of Hipparchus, B.C. 525, according to Clinton. There is nothing irreconcilable in these dates, though rather distant; since he

lived to the age of 85. It is said that he was unable to take any food except raisins, from extreme old age, and that he was at last choked by a grape-stone, but this anecdote bears too much the appearance of a poetical fiction, founded on the uniform tenor of his writings. He was held in high esteem by Polycrates, tyrant of Samos, and Hipparchus, son of Pisistratus, tyrant of Athens, two of the most eminent men of their age. The latter, we are told by Plato, (Hipparchus, 228 Steph.) sent a fifty-oared ship to bring the Teian poet to Athens. His old age seems to have been spent at Abdera in Thrace, whither the Teians emigrated, and founded a new city, when Teos was attacked by the Persian troops of Cyrus, commanded by Harpagus (B.C. 538). Some persons have pretended that an amorous connexion existed between Anacreon and Sappho; and there are verses extant, said to have been addressed by Anacreon to Sappho, and by Sappho to Anacreon; (Athenæus, xiii. 598-9, ed. Casaub.) but this involves a manifest anachronism. Of his personal character we know little; but if his own testimony of himself is to be believed, his life was spent in a course of debauchery and drunkenness; love and wine being the only things which he professes to think worth a wise man's attention. Athenæus, however, (x. p. 429, ed. Casaub.) and Madame Dacier, consider him to have been a man of temperate habits, and regard this garb of immorality merely as a poetic assumption. A statue was erected at Athens, representing him as a drunken man in the act of singing.

Some of the odes of Anacreon are written in the Ionic dialect, and generally in the iambic measure. Suidas says that he also wrote Elegiacs; but none of these remain. His extant poems are entirely amatory and convivial, and are generally admitted to afford the best specimens extant of this kind of composition. As such they have been much admired, and very frequently imitated and translated. Few, however, have succeeded in preserving the elegant simplicity of Anacreon, who seldom indulges in the forced conceits and extravagant prettinesses which so often disfigure the poems of his imitators. Some of the odes attributed to him are very deficient in real poetic feeling, and savour very little of the character of that remote age in which the writer lived. Some also, if we may judge from the language, are undoubtedly the productions of an age long after that of the poet. Of those who have attempted to present him in an English dress, the most celebrated, and the most successful, are Cowley, who translated twelve odes, and Moore. But the translations of the former should rather be called paraphrases; and the version of the latter is too much loaded with ornament, too studiously brilliant, to convey an exact idea of the style of his original. Some pretty specimens of the poet (including one or two of Cowley's translations) will be found in Merivale's *Anthology*.

Anacreon was first edited by H. Stephens, who got possession of two manuscripts, and published them, after careful collation, in 4to., in 1554. Many learned men at the time believed this to be a literary forgery, a supposition highly honourable to Stephens' powers of Greek composition; but this notion was dispelled by the discovery of the Vatican manuscript. It has been doubted, however, whether all the odes bearing the name of Anacreon, though ancient, belong to that poet. Pauw and Fischer believe the greater part of them to belong to authors of much later date. Tanaquil Faber stigmatised the 6th, 18th, 23rd, 24th, 25th, 26th, 27th, 32nd, 39th, 41st, 50th, 51st, 53rd, and 55th as spurious, chiefly on the ground of metrical inaccuracy, and of their being written in the Dorian, instead of the Ionian dialect. His daughter, however, the celebrated Madame Dacier, who translated Anacreon into French, does not always think him justified in rejecting them. A doubt has recently been suggested (Merivale's *Anthology*), whether the poems now passing under the name of Anacreon are those which were extant in the time of Horace, on the ground that there is only one passage in Horace which appears to have been taken from the Grecian lyricist; that beginning 'Vitas hinnuleo me similis, Chloe.' (Od. i. 23. l.) This argument, however, does not appear conclusive.

The best edition of Anacreon, we believe, is by Mehlhorn, Glogau, 1825; the third of Fischer, Lipsa, 1793; and Brunck's second edition, Strassburg, 1786, are also highly spoken of. There are many pocket editions of this author, and many remarkable only for typographical luxury, which we need not here particularise.

ANADYR is a river in Siberia, little known, and prin-

cipally remarkable for being the only considerable river of the globe, whose sources lie within the Polar circle, between the 68° and 69° N. lat. It rises in a lake in that range of the *Aldan* mountains, which traverses the north-eastern extremity of Asia, and terminates in Cape *Tshukotshkoi-Noss*, at Behring's Strait. The first third part of its course is directed to the south-west through nearly 3° of lat. till it passes to the south of the Polar circle. It then turns suddenly to the east, and continues in this direction, though declining insensibly to the south; but the lower part of its course lies nearly parallel to the Polar circle, at the distance of about 2½° of lat. In its eastern course it passes through 13° of long. It falls into the Bay of Anadyr, a large gulph of the Sea of Kamtschatka, forming an estuary at its mouth. The whole course of this river is upwards of 500 miles.

The country which is traversed by this river is almost entirely covered with rocky, naked, and barren hills, which sometimes rise to the height of mountains, though, as it seems, they do not attain the line of eternal snow. As the winter lasts about nine months, and all this time the ground is frozen and covered with snow, even the patches of low ground along the river are not available to the rearing of cattle; and the rein-deer and the dog are the only domestic animals of the nations which inhabit this corner of the world. The rein-deer in a wild state is very numerous, distinguished by its spotted skin, and forms the most important object of chase with the inhabitants. The greatest part of the population inhabit the country about the mouth of the river, and the small bays in its neighbourhood, where the great number of fish and marine animals, especially of morses (*Trichechus Rosmarus*, L.), affords them abundant food. These people have fixed habitations, but those who live on the produce of their herds of rein-deer, and of the chase, wander about like the Laplanders.

The country on the north of the river is inhabited by the *Tshukshes*, who, according to Captain Cook, are not of a diminutive size, as was formerly believed, but rather tall, well made, and strong. They have defended themselves with valour and success against the Russians, and are not obliged to pay a tribute like the other nations of Siberia. To the south of the Anadyr, there is another nation, the *Korakes*, who are neither so tall, nor so well made as the *Tshukshes*, nor so brave. They are subject to the Russians, and obliged to pay an annual tribute. (Captain Cook's *Third Voyage*, Georgi's *Travels*, and the *Map* in Pallas' *Travels*.)

ANAGA'LLIS, a genus of the natural order *primulaceæ*, among which it is known by its flat, or wheel-shaped corollas, and by its capsule opening into two halves, of which the upper fits the under like the lid of a box. A very common species is the *pimpernel*, or *poor man's weather-glass*, so called because its flowers generally open at eight in the morning and close in the afternoon, and also refuse to expand in rainy weather. It is a little trailing plant with brick-red flowers, very abundant in corn fields; it was once thought useful in cases of madness, especially such as arose from the bite of rabid animals, but it is in no esteem at the present day. A far more beautiful species is the *anagallis tenella*, which grows in the drier parts of marshes, along with *pinquicula* and *drosera*; it has delicate flesh-coloured flowers, in the centre of which grows a cone of stamens covered all over with glittering transparent hairs; and these and its peculiarly neat appearance, entitle it to be called the queen of British wild flowers. One or two foreign species, with large blossoms, are cultivated in greenhouses.

ANAGNI, the ancient Anagnina, once the capital of the Hernici, is now a town of between 5000 and 6000 inhabitants, in the Campagna of Rome, with a bishop's see. It stands on a hill above the valley of the Sacco, near the Via Latina, or road leading into the kingdom of Naples by San Germano, in the middle of a fertile, agricultural district. It is the residence of many noble families, twelve of the oldest of which are called the *twelve stars of Anagni*, having at their head the family of Caetani, from which sprung Pope Boniface VIII., and that of Conti, which has given the Church of Rome four pontiffs, among whom is Innocent III. Anagni often afforded a refuge to the popes during the troubles of the middle ages. Here Alexander III. excommunicated Frederic Barbarossa, and here the turbulent and irascible Boniface VIII. was surprised and made prisoner in 1303, by the Colonna faction, stimulated by his enemy Philip le Bel of France; owing to this affront, the

old man soon after died of grief. It lies 35 miles east by south of Rome.

ANAGRAM signifies a new word formed out of the letters of any given word by the process of writing them over again, as the term literally signifies, or placing them in a new order. Sometimes the anagram is formed out of two or more words, and it may be itself always either one word or several. Some traces of this species of trifling have been detected in the writings of the ancients; but the taste for it does not seem to have spread much among the Greeks or Romans. Although instances of the use of the anagram for various purposes may have been discovered of an earlier date, the artifice appears to have first become fashionable in modern literature in the early part, or towards the middle, of the sixteenth century. Many authors, instead of putting their names on the title-pages of their works, have, with an affectation of modesty, used the anagrams of their names. At one time also the anagram was much made use of by mathematicians in announcing discoveries, the credit or property of which they wished to secure to themselves without revealing the secret in which they consisted. Huyghens, Galileo, and Newton, intimated several of their discoveries in this way. (See the *Life of Galileo* in the *Library of Useful Knowledge*, chap. viii.)

ANALEPTICS, from a Greek verb which signifies to restore, comprise all the means, whether medicines, diet, or regimen, which are generally employed to restore the vigour of the system when it has fallen below the healthy standard, either from previous disease or any other cause. The term analeptic was formerly applied indiscriminately to any medicine which increased the powers of the system, whether it belonged to the class of stimulants or to the class of tonics; but as the progress of chemistry, anatomy, and physiology has enabled us to recognize a difference in the chemical composition of members of these two classes of medicinal agents, as well as in their manner of acting upon the human frame, we propose to limit the application of the word to the latter of them, or to tonics, reserving the consideration of the other till we come to the word stimulant. The following brief explanation of their effects will suffice to justify this proceeding. Stimulants act primarily on the nervous system, while tonics act primarily on the muscles and blood-vessels. Stimulants render the movements more frequent; tonics render them stronger. Stimulants, as we see with wine, exhaust the excitability; tonics, within a certain limit, maintain it. The action of the one is immediate and transitory, that of the other is slow and progressive, but more permanent, as is the case from Cinchona bark, or food. To take an example from their effects on the stomach, excitants quicken the digestion, as we see with capsicum or cayenne pepper, which we take with articles difficult to digest, as salmon; while tonics render the digestion more perfect, as occurs when we use cinchona in convalescence from disease. Though the most perceptible effect of tonics be upon the muscular system, as it is by a display of its powers that we judge of strength, yet the whole system feels the benefit of them when appropriately administered. Every person knows that he can, at one time, lift a weight with ease which, at another time, he cannot move but with difficulty and exertion. In the former case, he is pronounced *strong*; in the latter, *weak*.

The nature of the muscular fibre need not be discussed here; it is enough for us to remark, that to execute its functions properly, it must be in a certain state of tension, that it may be possessed of sufficient elasticity. A cord proceeding from a fixed point cannot influence a moveable body till it be drawn tight; so a muscle cannot raise a limb unless it possess a certain degree of tightness. The difference of the power of muscles varies greatly, according to the state of health or disease of the individual. If a muscle be taken from an animal in good health, it will not only bear a greater weight than the same muscle taken from an animal which has long been sick, but the former will be many days before it goes to decay and allows the weight to drop, while the latter will decay very speedily.

To maintain the muscular fibres in this condition, a due supply of blood and of nervous energy is requisite. The sources of these are in a healthful and vigorous digestion, and as this rarely goes on when the system is much disordered, or suffering under general or considerable local disease, scarcely any morbid action, or even the natural exercise of mind or body, if pushed to an extreme, can continue without producing debility. Tonics are, sooner or later,

required, seldom, indeed, to remove disease, but to obviate its effects, or that of the treatment it has been necessary to employ. The use of these requires the greatest circumspection, for, till we have removed the cause of the disease, they can rarely be of service; on the contrary, they often do harm.

We have above pointed out the connexion between the state of the digestive functions and the energy of the other functions, and it is important to bear in mind that anything loading and oppressing the stomach and bowels will lessen the tone of the system, diminish the disposition for exertion, and clog alike the action of mind and body. A judicious practitioner will here give, according to circumstances, an emetic or a purgative, and repeat this last for three or four days successively: in proportion as these act well, the languor and listlessness disappear, the mind resumes its wonted activity, for the cloud which had obscured the mental faculties is dissipated, and all again is energy, elasticity, and strength. An unskilful practitioner, and still more frequently the patient or his friends, would recommend some stimulant, a little brandy, or some bitters, under the influence of which all the symptoms become aggravated. It is a still worse case when the debility which occurs at the commencement of fevers, particularly ague and typhus, is so treated, though this is not so common an occurrence. A state of great irritation (morbid sensibility), or subacute inflammation of the mucous or inner membrane of the stomach, is a frequent condition of that organ with the inhabitants of towns, particularly among merchants and others engaged in extensive business which engrosses their whole attention, giving rise to much anxiety and leaving little time for exercise or food at proper times. The employment here of tonics, in the first instance, will only convert a manageable case into a difficult and serious one. It is, therefore, rather in the stage of convalescence from acute disease that tonics are required, and as a sequence to other medicines, than articles to be employed in the commencement, if we except some affections of the nervous system.

We need not enter into details respecting the particular action of tonics upon each set of organs of the body, as it may be stated generally that they all, sooner or later, begin to execute their functions more vigorously, the stomach first feeling the beneficial effects. But this state of improved action follows their use (i.e., when they are medicinal or material tonics) only for a time; for their continued employment leaves the stomach in a state of debility, perhaps greater than at first—a fact of which we should never lose sight. These remarks will, we trust, induce all to observe caution both in taking upon themselves to use the articles termed analeptics merely because they feel weak, without knowing what is the cause of the weakness, or in urging their friends to have recourse to them at the commencement of disease, or even when it is subsiding, as more relapses are occasioned by a premature employment of tonics, whether medicinal or dietetic, than by all other causes combined.

It is impossible to enumerate here, and give directions for the use of, all the analeptics, comprising, as they do, medicines, food, and regimen. The medicines are either from the mineral or vegetable kingdoms: when the former, they are chiefly preparations of the metals, as the salts of iron and flowers of zinc (oxide of zinc); from the latter they are invariably bitter substances, as Cinchona bark, Calumba, quassia, chamomile, &c. The analeptic means which fall under the head of regimen are, bathing, exercise, and the diversion of the mind.

The employment of the medicines will be stated under the diseases to which they are suited; bathing will be treated of under that head: it is, therefore, only upon the last two means that we will make any remarks here.

An examination of the human frame demonstrates that it was intended for motion, alternately with repose, and not for a state of absolute quiescence. Nor is the mind, which is furnished with so many faculties and provided with so many organs of sense, which serve to connect it with the external world, less calculated for active exertion. Any attempt to contravene the law of nature which enjoins a reasonable exercise of mind and body, brings a punishment upon the individual; the mind which he allows to be inactive loses the capacity for exertion, when required, and the body becomes a prey to disease in some shape or form. The action of the muscles is necessary to aid in circulating the blood and in completing the process of digestion, as well as

to ensure a regular motion of the bowels. Where the muscles are not exercised, the blood, instead of reaching the surface and the extremities, accumulates in the large internal trunks, leaving the skin dry and bloodless, as seen in young chlorotic females, who, instead of appearing buoyant with life in every limb, are as pale, and almost as inanimate, as a statue. Disorders of the nervous system, as hysteria, likewise show themselves. These states can only be warded off by regular exercise. The rising generation would be much benefited, if instruction in any branch of natural history formed a part of their education; young persons would then be furnished with motives for taking exercise out of doors—to the manifest advantage of the figure of the body and the tendencies of the mind. This is well explained and enforced in a note (p. 101) to a small work called *Botanical Geography*, published by Relfe, Cornhill.

Where older people have neglected exercise, it is more difficult to find means to induce them to resume its use; but some such device as the following may be tried: 'Ogul, a voluptuary, who could be managed but with difficulty by his physician, on finding himself extremely ill from indolence and intemperance, requested advice:—"Eat a basilisk stewed in rose-water," replied the physician. In vain did the slaves search for a *basilisk*, until they met with Zadig, who, approaching Ogul, exclaimed, "Behold that which thou desirest! But, my lord," continued he, "it is not to be eaten; all its virtues must enter through thy pores; I have, therefore, inclosed it in a little ball, blown up, and covered with a fine skin; thou must strike this ball with all thy might, and I must strike it back again, for a considerable time, and by observing this regimen and taking no other drink than rose-water for a few days, thou wilt see and acknowledge the effect of my art." The first day Ogul was out of breath, and thought he should have died of fatigue; the second he was less fatigued, and slept better. In eight days he recovered all his strength; Zadig then said to him, "There is no such thing in nature as a basilisk! but *thou hast taken exercise and been temperate, and hast, therefore, recovered thy health!*"

The Indian rubber, or caoutchouc balls will be found as useful for those confined by the weather within doors during the winter months, as the ball of Zadig.

It is possible to fatigue the body beyond a proper point, in which case repose becomes necessary; but this is a rare occurrence compared with the instances where the mind is stretched beyond its natural power to bear by the ambitious student, the covetous and care-worn merchant, or the adventurer in political life. If, in consequence of long-continued exertion, the balance of the mind be not already lost, abstraction from his books for the one, and a withdrawing from their pursuits for the others, with change of scene and occupation, must be enjoined: by doing this before it is too late, each may, in time, return to his usual station, to be useful in his sphere to himself and others, and may still be permitted to enjoy the greatest of earthly blessings,—a sound mind in a healthy body.

ANALOGY is the similarity of ratios or relations. A *ratio*, or *relation*, means that two objects (which are called the *terms of the ratio*) are considered together in reference either to some quality which they have in common, or to some manner in which one has affected the other. Thus, two things may stand in a certain relation to each other in respect of their quantity, magnitude, shape, colour, strength, height, &c.; in which cases the subject of comparison is common to both, and belongs to them to a greater or less amount. Thus, when we say that one thing is larger, taller, thicker, smaller, darker, more beautiful, more lasting, more desirable, more formidable, more probable, &c. than another, we mean that each of the pairs in question having in common the quality referred to, the former has it in a greater degree than the latter. These, which might be called *ratios of degree*, differ altogether from the other class, which includes all those relations arising from the manner in which one term of the ratio has affected the other, or is necessarily connected with it, and not from any attribute which they possess in common. Thus, we may speak of the relation of God and man, of the relations of men as members of the same political society or of different political societies, of the relation of a bird to its egg, of a tree to its fruit, &c.; in which instances some act done by one to the other party, or by both reciprocally, or some influence which one term has exercised over the other, is signified, and not

any quality or attribute common to both. In some cases of the latter kind there are words which express each term of the ratio *in respect of the relation*; and, therefore, they mutually imply each other. Such are, for example, parent and child, debtor and creditor, agent and principal, lessor and lessee, &c. As in these cases it is impossible to conceive the one without conceiving the other term, the latter might be called *ratios of implication**, as distinguished from those ratios in which a comparison is made of qualities existing independently in the things compared. For example, there cannot be a husband without a wife, or subjects without a sovereign, nor is there any quality which a husband has, as husband, independent of the wife, or the sovereign as sovereign independent of the subject; but although there cannot be a short man or a tall man without a man of middle size, yet the height of the short or tall man is an absolute quantity, and independent of the comparison. In the cases of a common property, or ratios of *degree*, there are words which denote the *relation* of one term to the other, as lowness, height, depth, and consequently imply both terms of the ratio; but there is no word which expresses the *term* of the ratio itself, as in the case of ratios of *implication*. (See Locke, *On the Understanding*, b. ii. c. 25.)

When two ratios are compared, that is, when it is affirmed that the relation of two things is like the relation of two other things, the two ratios together form an *analogy*, and each pair of the corresponding terms of the two ratios is *analogous*. Thus, the bark stands in a similar relation to a tree as the skin to an animal; and consequently the one bears an analogy to the other: so the feathers of a bird are analogous to the hair of a quadruped, the admiral of a fleet is analogous to the general of an army. Of this nature are all fables and parables, in which the circumstances of the person to whom the lesson is addressed are illustrated by a parallel case, that is, by supposing a relation similar to that in which he is placed. Thus the case of a man who affects to despise what is out of his reach, is vividly portrayed by the fable of the Fox and the Grapes; and so in other cases: the parables of Holy Writ are instances of a similar mode of instruction, only the examples are not, as in fables, chosen among irrational animals. [See *FABLES*.] The same is the principle of grammatical and etymological analogy: thus, if *to give* is conjugated *I give, thou givest, he gives, to live* would be conjugated *I live, thou livest, he lives*; the inflexions of the verbs standing in a like relation to each. So the verb *rattle* is derived from *to rate*, as *prattle* from *to prate*, and *hobble* from *to hop*: *little* is derived from the old word *lite*, as *mychel* or *myckle* from *much*, &c. Thus, *kingly* is to *king*, as *royal* to the French *roy*, and *regal* to the Latin *rex*, or rather to the root *reg*, which two latter substantives have not been naturalized in English. The formation and development of language proceed almost exclusively on this principle.

From what has been said it is evident, 1. That in an analogy there must be two ratios, and consequently four terms or objects of comparison; and 2. That there is no connexion between resemblance and analogy, and that things may be analogous without being similar, and similar without being analogous. 1. With regard to the first of these propositions, it should, however, be observed that, although there must be four terms, it is not necessary that all the four terms should be different. If there was such a necessity, one of the chief uses of analogy, as an engine of argument and discovery of truth, would be destroyed. All that is required is, that there should be two distinct ratios: of what terms those ratios may consist is indifferent. Thus, in the case of brethren, the parents are in an analogous situation in respect of each brother: so the grandfather is to the son as the son is to the grandson. In such cases as these, both the relations are known: frequently, however, the relation in which one thing stands to another being known enables us to discover, with greater or less certainty, the relation which the same thing bears to something else, which is unknown. Thus the moral government of mankind by the Deity, in this world, furnishes a means of conjecturing his religious government, both in this world and the next, independently of a Divine Revelation. So the past conduct or performances of a nation, a government, a minister, a

* There are some words used to denote the state of one of the terms of a ratio of implication when the relation has been destroyed: thus, *widow*, means an unmarried woman who was once a wife, *orphan*, a child whose father is dead, &c. Sometimes the terms denoting a relation are applied by anticipation before the ratio begins to exist: thus a person is popularly called an *heir* in the ancestor's lifetime, although *nemo est heres viventis*.

general, a lawyer, an architect, a painter, a poet, a racehorse, &c., afford materials for judging what will be their future conduct or performances under similar circumstances. It is to this most important use of analogy that Quintilian refers, when he says that its purpose is to discover what is unknown by what is known, to prove what is uncertain by what is certain.

2. Resemblance being the similarity of some sensible quality, as form, colour, taste, smell, or sound, it has evidently no connexion with analogy; and if things analogous happen to resemble one another, their resemblance is a mere accident, independent of their analogy. Thus, two brothers may resemble each other; but they might equally resemble each other without being brothers, and would be equally brothers if they did not resemble each other. The confusion of analogy and resemblance is, however, of very frequent occurrence, and numerous examples of it might be cited. It is, we believe, the opinion of several commentators on the New Testament, that, in the passage of St. Matthew where the Holy Ghost is stated to have descended 'as a dove,' it is meant, not that the Holy Ghost descended in the form of a dove, but that the Holy Ghost descended as a dove descends. In a similar manner, Homer says that Apollo and Minerva sat, like birds, on the branches of a tree near the Scæan gate of Troy; by which he meant, as birds sit on the branches, so did the god and goddess: but Pope, in his translation, represents them as undergoing a change of form, and assuming the appearance of birds.

The above examples may serve to illustrate an error of frequent occurrence in the use of the argument from analogy. As, in the instances just cited, the similitude is extended beyond its proper limits, and it is supposed that because the two objects are like each other in *one* respect, they are like in *all*; so the analogy between two things is sometimes pressed beyond its just application, and is carried out of the bounds of the relation in virtue of which the comparison was made. Thus the injunction to be 'as wise as serpents and harmless as doves,' does not recommend to our imitation either the venomous ferocity of the one, or the helpless timidity of the other animal. Two false analogies may be mentioned which at one time had a powerful influence on political discussions, nor are even now quite exploded, viz., that the existence of the human race, and the existence of nations, are analogous to the life of a single man. For some purposes these two relations might doubtless be compared; but when it is argued that a nation will pass through a series of changes corresponding to the childhood, manhood, and old age of a single human being, or that the early state of mankind was like the innocence and simplicity of an infant, the comparison is unwarrantably wrested out of the range of its proper application. The notion of the corruption of a nation by luxury appears to have had a like origin; for *single individuals* may be, and often are, depraved by a sudden change from poverty to riches; but the process by which a *nation* enriches itself, is a mark of habits very different from vicious indulgence and effeminate indolence.

All analogical comparisons are made by means of abstraction; a certain attribute belonging to each of two objects is considered separately from all the other attributes which those objects may possess, and a comparison is instituted between them in respect of that common attribute. Thus, the analogy between the skin of an animal and the bark of a tree arises from our leaving out of our consideration all those circumstances in which they differ, such as their colour, consistency, animation, sensibility, &c., and paying attention only to the use of each, as the outward covering, in one case, of the body and limbs of the organized being, and in the other, as the outward covering of the woody matter of the tree. [See ABSTRACTION.] It is by a like process of abstraction, that an extended and vague meaning is given to many general terms, particularly those belonging to the moral sciences; and in this manner they are applied to objects to which they are only *analogous*, and which they do not properly designate. Thus a *law*, in its original and strict sense, is a general command of one rational being to another: but as one of the effects of such a command is to produce a uniformity of conduct in the person or persons to whom the command is addressed, the word has been transferred to inanimate objects in which there is a uniformity of phenomena; and although there is no command received, no command given, and no intelligence to work upon, we yet speak of the laws which regulate the motion of matter, the

succession of the seasons, the diffusion of heat and light, and other physical appearances which follow in a constant relation of cause to effect. In this case the proper characteristics of a law being neglected, one of its relations is alone considered; and hence the analogical application just mentioned. When such an application is made, not from a vague or inaccurate use of language, but from a desire to add beauty or energy to the expression by the transfer of words, this transfer, and sometimes the transferred word itself, is called a *metaphor*. Thus when Shakspeare represents Macbeth as saying of Duncan that

His virtues
Will plead like angels, trumpet-tongued, against
The deep damnation of his taking-off,

he means that Duncan's virtues will arrest the public attention as forcibly as the sound of trumpets. The analogy is obtained by referring the two objects compared to the general class of things which instantly attract universal notice. [See METAPHOR.]

The word *proportion* properly signifies an analogy of quantities or magnitudes, as a proportion of numbers, lines, surfaces, &c. In popular usage, however, *proportion* is commonly made synonymous with *ratio*, as when we speak of the proportion of deaths to births, the proportion of wages to profits, the proportion of convictions to commitments, &c. Sometimes also it is used for *portion*, as when we speak of a large proportion, a small proportion, a fair proportion; in this case, however, a ratio is meant, as the *part* is considered as bearing a certain relation to the *whole*. On the subject of Analogy, see Aristotle's *Poetic*, c. 21; *Rhetoric*, b. ii. c. 2; *Hist. An.* l. c. 1; Coplestone in the Appendix to *Whately's Rhetoric*; Whately's *Rhet.* part i. c. 2. s. 6.

ANALYSIS, a Greek word, signifying literally *the art of unloosing or untying*; its opposite is *synthesis*, which is the act of putting together. The modern meaning of the term analysis, is the process by which facts, results, or reasonings are separated into their simple and component parts, or by means of which a simple truth is obtained, when given in a more complicated form; so that, in its most general sense, the greatest part of human knowledge consists in the results of analysis. It is, however, for the most part applied in a more particular manner to the methods employed in those branches of inquiry, which most strikingly exhibit direct analysis; viz., mathematics and natural philosophy, particularly chemistry. By a very incorrect misnomer, algebra, the differential calculus, &c., have been called by the general name of *analysis*, in opposition, not to *synthesis*, but to *geometry*, in which latter science synthetical methods are most usually applied. This perversion of the term prevails on the Continent to such an extent, that it must always be taken for granted, that '*analyse*' stands for the algebraical branches of pure mathematics. In this sense it is again subdivided into 'algebraical analysis' and 'infinitesimal analysis,' the latter including the fluxional or differential calculus. And by 'geometrical analysis' is frequently understood the application of algebra to geometry. It must, however, be remarked, that the exact sciences have appropriated this word, simply because in these branches of knowledge the use of analysis has been made most conspicuous.

Confining ourselves to the primitive meaning of the term, it is obvious that all discovery must be entirely either the work of analysis or of accident; and that, therefore, geometrical analysis must be as old as geometry. Nevertheless this does not appear from the earliest treatises. The work of Euclid is strictly synthetical. Instead of taking the proposition asserted, and examining it by means of preceding propositions, and in the mean time assuming it to be true, in order to ascertain whether the results deduced from it agree or disagree with what has been already proved,—Euclid first enunciates the point which he means to establish, and then proceeds to put together the considerations by which it is demonstrated, leaving the learner nothing to do but to judge of the truth or falsehood of each argument as it arises, without taking into consideration the methods by which the arguments themselves were first obtained. This is the natural and proper method of teaching what has already been discovered, for its own sake; not only because it neglects to introduce difficult and embarrassing considerations, and allows of the subject being broken up into portions which are easily learnt at one time, but because there is, in reality, no perfectly general and certain method of analysis which can be made obvious to the beginner. In attempting the analysis of a new problem,

though the discoverer will naturally first try those methods which have been successful in preceding cases, he has no means of assuring himself beforehand which will be successful. The chemist is similarly circumstanced. Let a new substance, or one supposed to be such, be presented to him, from which he is required to find out whether it is already known, or if not, of what it is composed. No effective analysis can commence without requiring the results of all his previous knowledge, for he must have some method of recognising each and every substance with which he is acquainted, previously to pronouncing whether or not that under consideration is one of them. He must then proceed to trials of that substance with various others, and nothing but the sagacity which arises from previous experience can direct him in his choice of the methods to be employed. No general rules of analysis can be laid down, that is, no processes which must end in the discovery of the component parts required. The same observations may be made on mathematical analysis. We give a geometrical instance, with its result, and the synthetical form of the proposition arising out of it.

The sides of a triangle ABC are cut in D, E, and F, by a straight line. Six segments are thus formed, AD and DB, whose sum is the side AB; AE and EC, whose sum is the side AC; and BF and FC, whose difference is the side BC. It is required to investigate the relation which exists between these six segments, if there be any relation.

Some relations will be thrown out of the question upon the slightest consideration: the sum of the six lines is not the same in every triangle, neither is their product. Leaving this unorganized method of examination, we recollect, that if CB were parallel to DE, the then similar triangles ADE, ABC, would give a well-known relation between AD, DB, AE, and EC. To try whether this may help us, draw CG parallel to DE, which gives the proportion

$$AD : DG :: AE : EC,$$

or if we represent the lines by the number of units which they contain,

$$AD \times EC = AE \times DG \quad (1.)$$

Because GC is parallel to DF, we have

$$GD : BD :: CF : BF,$$

$$\text{or } GD \times BF = BD \times CF \quad (2.)$$

and the equations (1) and (2) multiplied together, and the result divided by the common factor GD, gives

$$AD \times EC \times BF = AE \times BD \times CF \quad (3.)$$

whence the relation required between the six lines is as follows:—Let them be separated into two lots of three lines each, in such a way that no two lines which have a common extremity are both in the same lot; then the product of the first three will be equal to the product of the second three.

If instead of asking for the relation, if any exist, between the six lines, the equation (3) had been given, and it had been required to detect whether it were true or false, the process would have been similar; and we should have found that the equation (3) is true, and a necessary consequence of the proposition, that a line drawn parallel to one side of a triangle divides the other sides into proportional segments.

The synthetical form of the preceding process differs from it much less on the paper than would be the case in the mind of a student, who had actually hit upon the solution in the progress of investigation. For, not being able to tell the various steps by which one of our readers would endeavour to arrive at the same conclusion, we are obliged to prompt him with a right guess, and thereby give him only a synthetical description of that which was in our minds an analytical process. It only remains, therefore, to make the demonstration synthetical in form, which, as will now be readily seen, will consist in stating the proposition to be proved, directing to draw CG parallel to DF, without giving any reason, and combining the steps of the preceding demonstration.

The geometrical analysis is generally ascribed to the

school of Plato; but, in reality, as we have already observed, must be of a date as early as geometrical reasoning itself. The use of PORISMS, or problems, [see also LOCUS] admitting an indefinite number of solutions, the establishment of the properties of the CONIC SECTIONS, and the various efforts made for the DUPLICATION of the cube and the TRISECTION of the angle, all of which were the work of the school already mentioned, most certainly increased the power of the analyst, that is, made the means of discovery more obvious and more successful: but there is nothing in the methods which entitles them to the exclusive appellation of geometrical analysis.

The peculiar distinction between algebra and geometry is, that the analytical method is pursued in the former from the commencement. The solution of a problem consists in inquiring into the consequences of the solution *supposed to be found*, by introducing at every step some known truth, such as will produce a more simple consequence, and thus reasoning backwards, so to speak, until at last the answer itself is directly produced in numbers, which was before implicitly involved in the conditions of the problem. The methods are more general than in geometry, that is, a larger number of problems may be solved by each process. The same observations apply still more strongly to the higher parts of algebra, and the differential calculus.

The solution of equations of the first four degrees, and the approximation to that of all higher degrees, render the analytical solution of a vast number of common problems a matter of certainty. The solution of differential equations, where that can be done, is an additional step of even a more important character. Within the last half century, mathematical analysis has made considerable approaches to a state which enables us to determine, almost immediately, whether a problem can be solved by such means as we possess, or not; no small advantage, when it is considered how much time was previously wasted in the attempt to attain results which have since been shown to be impossible.

ANALYSIS. Chemical analysis is the separation of compound bodies, either into their simpler or their elementary constituents. When merely the number and nature of these are ascertained, it is termed *qualitative* analysis; but when their proportions also are determined, the analysis is *quantitative*. If the analysis consist only in determining the quantities of the *simpler* constituents of a compound, it is *proximate*, as when carbonate of potash is separated into carbonic acid and potash: but when the operation is extended, and the carbonic acid is resolved into carbon and oxygen, and the potash into potassium and oxygen, the analysis is *ultimate*; for neither carbon, oxygen, nor potassium is divisible into two or more kinds of matter.

ANAMOUR, the antient Anemurium, is the most southern part of Asia Minor, and described by Strabo (p. 669) as the nearest point of the mainland to Cyprus. It is in 36° 2' N. lat., 32° 50' E. long. 'Cape Anamour terminates on a high, bluff knob, one side of which is inaccessible; the other has been well fortified by a castle and outworks, placed on the summit, from whence a flanked wall with towers descends to the shore, and separates it from the rest of the promontory.' There are two channels cut in the rock, several miles in length, and on different levels, which supply the castle with water; where they are carried across the ravines, they rest on arches. Here are the remains of two theatres; and beyond the walls a great number of detached tombs, each constructed of two chambers, with arched roofs. No inscriptions were found. The place is now altogether deserted; and the present castle of Anamour is about six miles east of the cape, on the edge of the sea. (Beaufort's *Karamania*.)

ANANASSA, or the **PINE APPLE**, is a genus of the natural order *Bromeliaceae*, found wild in the woods of South America, and now commonly cultivated in the gardens of rich Europeans. It is distinguished from the bromelia, to which it was once referred, by its succulent fruit collected in a compact head.

Of *Ananassa sativa*, the common pine-apple, a great number of varieties are known, of which the Moscow and common queen, the black Jamaica, and the Antigua queen are the best for summer use, the Enville and the Trinidad the largest, the black Jamaica the best for winter use, and the blood-red the worst for any purpose or season.

The fruit is a mass of flowers, the calyxes and bractes of which are fleshy and grow firmly together into a single

head; it is the points of these parts that together form what gardeners call the pips, that is to say, the rhomboidal spaces into which the surface is divided. When wild, pine-apples bear seeds like other plants; but in a state of cultivation, generally owing to the succulence of all the parts, no seeds are produced, and consequently the plants can only be multiplied by suckers, or by their branches, which gardeners call the gills and crown. The latter, which surmounts the fruit, is in reality the end of the branch round which the flowers are arranged, and if it has any tendency to ramification, as sometimes happens, it becomes what is called double. In the island of Penang in the Indian archipelago, there is a sort, all the flowers of which always change into branches, each of which bears a pine, terminated by a crown, so that a great cluster of pine-apples is produced by a single stem; specimens of this sort are called double pines. They have never been produced in England.

The pine-apple was undoubtedly unknown before the discovery of America; its incomparable flavour soon, however, caused it to be introduced into Africa and Asia, where, in a suitable climate, it multiplied so rapidly as to acquire as firm a footing in those countries as their aboriginal plants. In Asia it has even improved so much in quality, that the Burmese pines, which have never yet reached England, are said to be the finest in the world. With this exception it is believed that we already possess the best varieties that exist; and it is undoubted that, except in the kingdom of Burma, the most delicious specimens of the fruit are produced in England. For the probable reasons of this, and the method pursued in the cultivation of the pine-apple in this country, see *PINE-APPLE*.

ANANIAS was a son of that Onias, the high priest, who, being exiled from Jerusalem, built a Jewish temple near Heliopolis, in Lower Egypt, and founded the town of Onion on the eastern frontier of the Delta. Ananias and his brother Helcias, or Chelcias, were appointed the commanders of the Egyptian army by Cleopatra, when she warred against her son Lathurus, in the year 102 B.C. Ananias remonstrated against the intention of Cleopatra to seize the dominions of her confederate Alexander Jannæus, and assured her that the Jews would take revenge if she succeeded in killing Jannæus. Cleopatra, considering that Ananias and Jannæus were related to each other, and that many Jews served in her own army, gave up her treacherous plan. (Jost's *Geschichte der Juden*, vol. ii. p. 309—311.)

ANANIAS (אנניאס) grace of Jehovah) is the name of several Jews. Ananias, the son of Nebedæus, was high-priest from the year 50-66 after Christ. He was sent to Rome by Quadratus, the governor of Syria, in order to exculpate himself concerning the quarrels of the Jews with the Samaritans; Agrippina interceded for Ananias, and he was set at liberty. He condemned the apostle St. Paul. (See Acts xxii. 23, 24; and xxv. 1.) At the commencement of the Jewish war, Ananias and his brother concealed themselves in an aqueduct, but were discovered and killed.

ANAPÆST, a foot in Greek and Latin metre, consisting of two short syllables followed by a long. It was sometimes called Antidactylus, as being the opposite of the dactyle, which consists of a long syllable followed by two short. Assuming accent in English to be the same thing with quantity in Greek and Latin, the word *temporal* would be an example of a dactyle, and the word *superioid* of an anapæst. From the tendency of English enunciation to carry back the accent towards the beginning of polysyllables, there are not many single words which make anapæsts in our language. But the foot frequently results from the union of two or more words; as in *Dō you hēir*, *Lēt ilōne*; and sometimes it is found in part of a single word; as, for instance, in the three middle syllables of the word *anticipation*. The predominance of dactyles in English, and of anapæsts in French, forms one of the most marked distinctions between the musical character of the one language, and that of the other.

ANAPÆSTIC VERSE, a species of verse composed of a succession of anapæsts. Among the Greeks, the anapæstic verse was freely used both in tragedy and comedy; some forms of it occur very often in Aristophanes. Both in tragedy and comedy, the anapæstic verse admits also dactyles and spondees. In English, only poems of the lighter sort have been usually written in anapæstic verse.

Anstey's *New Bath Guide* may be quoted as a well-known example. The line is often reduced to eleven syllables, by the retrenchment of the first, or the substitution at the beginning of an iambus instead of the anapæst. Thus, in the following lines from the work just mentioned,

For I'm told the discourses of persons refined
Are better than books for improving the mind,
But a great deal of judgment's required in the skimming
The polite conversation of sensible women,

it will be observed, that the first foot of the second line consists only of one short or unaccented syllable followed by a long; and a similar retrenchment might be made of the commencing syllable of any of the others, without spoiling its prosody.

ANAPLI. [See NAUPLIA.]

ANARCHY properly means the entire absence of political government; the condition of a society or collection of human beings inhabiting the same country, who are not subject to a common sovereign. Every society of persons living in a *state of nature* (as it is termed) is in a state of anarchy; whether that state of nature should exist in a society which has never known political rule, as a horde of savages, or should arise in a political society in consequence of resistance on the part of the subjects to the sovereign, by which the person or persons in whom the sovereignty is lodged are forcibly deprived of that power. Such intervals are commonly of short duration; but after most revolutions, by which a violent change of government has been effected, there has been a short period during which there was no person or body of persons who exercised the executive or legislative sovereignty,—that is to say, a period of anarchy.

Anarchy is sometimes used in a transferred or improper sense to signify the condition of a political society, in which, according to the writer or speaker, there has been an undue remissness or supineness of the sovereign, and especially of those who wield the executive sovereignty. In the former sense, anarchy means the state of a society in which there is no political government; in its second sense, it means the state of a political society in which there has been a *deficient* exercise of the sovereign power. As an insufficiency of government is likely to lead to no government at all, the term *anarchy* has, by a common exaggeration, been used to signify the small degree, where it properly means the entire absence. [See SOVEREIGNTY.]

ANAS, the duck, a genus of birds under which Linnæus included a great number of species now separated into several genera by recent naturalists; and even Temminck, Drapiez, and others, who adhere to the original Linnæan genus, find it convenient to separate the goose and the swan, and to distinguish the others according as they possess or want a loose membrane covering the hind claw. Illiger ranks the swan with the ducks, from which he separates the goose. Baron Cuvier and Lesson have proposed a great number of subdivisions, and Leach and Fleming have established several new genera. The following are Temminck's characteristics, with some slight modifications:—

The bill of middle size, strong, straight, covered with a thin membrane, and always depressed towards the point, which is rounded, blunt, clawed; margins of the two mandibles toothed with laminae. Nostrils almost at the surface of the bill, at some distance from the base, somewhat oval, half closed by the flat membrane that lines the nostrils. Legs short, feathered to the knees, drawn back towards the belly; three toes placed before, wholly webbed; hind toe free, and jointed high upon the shank (*tarsus*). Wings of middle size, the first quill either as long as the second, or rather shorter.

ANASTASIUS I., Emperor of Constantinople, succeeded Zeno, A.D. 492, through the interest of Ariadne, Zeno's widow, who afterwards married him. Anastasius was then sixty years of age. He was called *Silentarius* because he had been one of the officers whose duty it was to maintain peace and silence within the precincts of the imperial palace. Longinus, Zeno's brother, who aspired to the throne, was sent to Alexandria, where he took priest's orders. The beginning of Anastasius' reign was favourable; he abolished several obnoxious taxes, and checked the abuse introduced by Zeno, of selling the public offices to the highest bidder. He also encouraged men of letters, and was himself a man of some learning. Theodoricus, king of the Goths, who, after defeating Odoacer, had made himself master of all Italy, sent an embassy to Anastasius, who recognised his title to the kingdom of Italy, and sent

him the purple in token of it. But their good understanding did not last long. Theodoricus invaded part of Illyria and Mœsia, and defeated the Greek troops near the river Margus, now the Morava in Servia. Anastasius, on his side, sent a fleet and army which ravaged the coast of Italy as far as Tarentum, in 508.

Anastasius became obnoxious, on account of his aversion, to the people of Constantinople, who pulled down his statues and dragged them through the streets; and he was himself assailed with a shower of stones while in the Circus, and with some difficulty saved his life. To add to his misfortunes, the empire was attacked by the Bulgarians, the Arabs, and the Persians. The Persians invaded Armenia, and took the town of Amida or Diarbekr on the Tigris, but were defeated by Justinus, who afterwards became emperor. A truce was concluded between Anastasius and Cabades, king of Persia, which lasted twenty years. Anastasius, like many other Byzantine emperors, had the vanity of appearing as a theologian, and of meddling in religious controversies. This nearly cost him his crown; his attempt to introduce some changes in the liturgy occasioned tumults at Constantinople, attended by fires and bloodshed. Several provinces also revolted, and raised to the command one Vitalianus, a Scythian, who advanced to the gates of Constantinople, and Anastasius only obtained peace on condition of becoming reconciled to the church. He had involved himself in disputes with Pope Symmachus, for defending the memory of Acacius, the late Patriarch of Constantinople, who had been excommunicated by Pope Felix II., under the reign of the Emperor Zeno. The Council of Chalcedon having declared the Bishop of Constantinople to be next in place to him of Rome, Acacius had contested this decree, and had endeavoured to assert his own precedence, which became a source of schism between the two sees. Anastasius' religious principles, however, seem to have been very unsteady, and he was even accused of favouring Manichæism. Anastasius died suddenly, in 518, at a very advanced age, and was succeeded by Justinus I.

ANASTASIUS II. Emperor of Constantinople. His original name was Artemius, while he was secretary to the Emperor Philipppicus Bardanes. After the deposition of Philipppicus in 713, he was proclaimed emperor, and sent a new exarch to Italy, and declared himself a follower of the Western church. Constantinople being threatened by the Saracens, Anastasius, to effect a diversion, sent a large fleet with an army to Alexandria, but the troops revolted on arriving at Rhodes, and returned to Constantinople, where they proclaimed emperor one Theodosius, a receiver of the taxes, who, however, alarmed at his dangerous promotion, ran away from them. The insurgents plundered and burnt part of the city, and Anastasius having retired to Nicæa, in Bithynia, was defeated and obliged to surrender, with permission to retire to a convent, and to become a monk. Theodosius III. was then proclaimed emperor in 716, but being unequal to the task, he resigned the crown the following year to Leo, called the Isaurian. Anastasius, from his convent at Thessalonica, made an attempt to recover the throne, and having obtained assistance from the Bulgarians, appeared before Constantinople. Leo, however, bribed the chiefs of the Bulgarians, who delivered Anastasius into his hands. Anastasius was beheaded with several of his followers, and their property confiscated by Leo, in 719.

ANASTASIUS I. Pope, a native of Rome, succeeded Siricus about the year 398. He was a contemporary of St. Jerome, who speaks highly of his probity and apostolic zeal. He condemned the doctrine of Origen, and he also expelled Rufinus from the communion of the church. The latter wrote an Apology which is found in Constant's collection of the *Epistles of the Popes*. Anastasius died in 402, and was succeeded by Innocent I.

ANASTASIUS II., a native of Rome, succeeded Gelasius I. in 496. He endeavoured to put an end to the schism then existing between the see of Constantinople and that of Rome about the question of precedence. He also wrote a congratulatory letter to Clovis, king of the Franks, on his conversion to Christianity. He died, after a short pontificate, in 498.

ANASTASIUS III., likewise a Roman, succeeded Sergius III. in 911, and died the following year.

ANASTASIUS IV., Cardinal Conrad, Bishop of Sabina, was elected Pope in 1153, after the death of Eugenius III. Rome was then in a very disturbed state, owing

to the schism of Arnaldo of Brescia and his followers. Anastasius died in 1154, and was succeeded by Adrian IV.

ANASTOMOSIS, from *ἀνά*, *through*, and *στόμα*, *a mouth*, signifies the communication of blood-vessels with each other by the opening of the one into the other. The blood-vessels are the tubes by which the different parts of the body are supplied with nourishment. If the blood-vessels destined to nourish a part be obstructed so that it cannot receive a due supply of blood, that part must necessarily die, or, as it is technically termed, mortify. But the blood-vessels are soft compressible tubes, liable, by innumerable circumstances, to have their sides brought so closely into contact as to prevent the flow of a single particle of blood through them. In order to prevent the consequences that would result to the system from the operation of causes thus tending to impede the circulation, provision is made for the freest possible communication between the main trunks of the blood-vessels and their branches, and between one branch and another. It will be shown hereafter [see **AORTA**] that all the arteries of the body spring from one great trunk which issues from the heart, and which passes from the heart through the chest, into the abdomen, where it divides into large branches which supply the lower extremities. In this course this vessel gives off innumerable branches, which supply different parts of the body, and these branches form innumerable unions with other branches which proceed from the main trunk of the artery. All the branches which form such communications are called *anastomosing* branches, and this union of branch with branch is termed *anastomosis*. Now so numerous are these anastomosing branches, and so competent are they to carry on the circulation, that if the main trunk of the aorta be tied in the abdomen, or even in the chest, the lower extremities will receive a sufficient supply of blood to maintain their vitality through these collateral or anastomosing branches. The knowledge of this fact enables the modern surgeon to perform with ease and safety operations which the surgeon of former times would have pronounced impossible. Anastomosis is of two kinds, that between large trunks, and that between small branches. When the communication is direct between two large trunks, there is no difficulty in conceiving that the circulation may readily go on though one of the trunks be obstructed, because the trunk which remains open may transmit a sufficient quantity of blood to nourish the part to which it is destined. But when a limb is supplied by one large artery only, and when that is obstructed, how does the limb receive a sufficient quantity of blood to support it? Suppose there is an obstacle to the free passage of the blood through its usual channel, namely, the main artery of the limb. What is the consequence?—the blood is driven in greater quantity, and with greater force into those branches which spring from the main artery above the seat of the obstruction. These branches, in consequence of receiving a greater influx of blood than usual, gradually enlarge in diameter, and transmit through them a proportionally larger quantity of blood. At the same time, the more minute branches, which anastomose with the branches given off below the obstruction, are in like manner dilated and admit a correspondingly free passage of blood to the inferior part of the limb. At first the circulation is in this manner carried on through a congeries of minute anastomosing arteries, but in a short time a few of these channels become more enlarged than the rest: as these increase in size, the smaller vessels gradually collapse, and thus ultimately a few large communications constitute permanent channels through which the blood is transmitted to the parts which it is destined to supply. Such is the beautiful provision established in every part of the body to secure to it a due supply of blood, if any obstacle should obstruct the course of this vital fluid through its accustomed channel.

ANATHEMA, a Greek word, properly signifying, a thing set apart and devoted. Among the Greeks a piece of armour or anything else which was offered to the gods, and placed in a temple, was called an *ἀνάθημα*, (*anathéma*), or offering. Tripods, votive tablets with inscriptions, such as may be seen in the Elgin collection of the British Museum, numbered 209 to 218, belong to the class of *anathémata*. But the dedication or setting apart might be to the powers of evil as well as to those of good, or, according to Pagan notions, to the infernal as well as to the celestial gods. Hence the word came, in one of its applications, to signify much the same thing with the word accursed. It is thus that it is principally used in the New Testament. In this

sense the form *anathema* (ἀνάθεμα) was employed, and not *anathéma*, though both are really the same word. In the decrees of popes and councils, also, a common form of expression is, whosoever shall do, or not do, or believe, or not believe, a particular act or dogma, 'let him be anathema,' that is, let him be held excommunicated, separated from the society of the faithful, and branded with the curse of the church. On the other hand, a heretic, when he renounced his errors and was received into the bosom of the church, was accustomed to declare his heresy 'anathema,' or a thing accursed. In English we more frequently use the term *anathema* in the sense of the curse or severe denunciation itself than for the object of the curse; as when we speak of the church directing its anathema against any particular opinion.

ANATIDÆ (*Leach*), the duck-kind, a group formed by Dr. Leach to include his genera formed from the great genus *Anas* of Linnæus, and comprehending *Oidemia*, *Somateria*, *Clangula*, *Nyroca*, *Tadorna*, *Spathulea*, *Querquedula*, *Anas*, *Cygnus*, and *Anser*. Lesson professes himself to be at a loss to apply properly these British generic names. He himself gives, as what he terms subgenera, *Maceranas*, *Macroramphus*, *Hydrobates*, *Histrionicus*, *Platypus*, *Fuligula*, *Micropterus*, *Clypeata*, *Tadorna*, *Moschatus*, *Anas*, *Anseranas*, and *Querquedula*.

ANATOLIA, or **NATOLIA**, is a geographical term now generally considered as synonymous in extent with Asia Minor. It is derived from the Greek ἀνατολή, (*anátolē*), the 'east,' or the 'part where the sun rises,' and, in this respect, may be compared with the French term 'Levant,' which is used to express generally the countries bordering on the eastern shores of the Mediterranean. The word *Anatolia*, as a geographical term, originated under the Greek empire, and referred to the country which lay east of the seat of government. *Anatolia* or *Anadoli*, in a more restricted sense, is used to indicate that tract of country which stretches along the western and a large portion of the northern shores of Asia Minor. Adopting such a restriction, geographers divide Asia Minor into three unequal parts, *Anadoli* already mentioned, *Karamania* on the south-east, and *Roum* to the north-east. But Captain Beaufort, who surveyed the southern coast of Asia Minor, remarks, that however convenient as a geographical distinction, the term 'Karamania is neither used by the present inhabitants, nor is it recognised by the government.' The Pasha of *Anadoli* (*Anatolia*) has military jurisdiction over all authorities within the barrier of the Euphrates. *Anatolia*, taken, then, in its extended sense, represents the whole territory contained within 36° and 42° N. lat., and 26° and 40° E. long. It is bounded on the north by the Black Sea, on the west by the Ægean, or Archipelago, and on the south by the Mediterranean; its eastern frontier extends to the Euphrates and Armenia.

If we were to attempt to name a natural boundary on the east for this portion of the earth's surface, which should be somewhat in accordance with the received notions as to its political limits, we might consider it as commencing at Cape Hynzyr on the Gulf of Scanderoon, and running between N.E. and N.N.E. along the mountain range of Amanus to the neighbourhood of Malatiah near the Euphrates, and up that river to the point (about 40° N lat.) where the Euphrates, from a course due east and west, takes a course to the S.W. From this point a line drawn along the meridian of 40°, and striking the Black Sea about twenty-five miles east of Trebizond, might be considered as completing the eastern boundary. But no *real* physical boundary exists in the northern part of the peninsula of Asia Minor, for the high plateaus and mountains which belong to the peninsula stretch eastward into Armenia.

The term *Asia Minor* is one of comparatively recent date: it was unknown to Greek, and, we believe, Roman geographers, at least under the early emperors; nor do we know when the term first came into use. It is, however, now pretty well established, and is the most commonly received term for denoting that extensive country of a peninsular form, the limits of which we have just attempted to define. From a notion early prevalent and long-continued, that the distance from the Gulf of Scanderoon on the south coast to the neighbourhood of Amisus (Samsun) on the north was much less than it really is,—arose a vague idea of *Asia Minor* (as we understand the term) being a kind of insulated mass from the rest of the continent. The Euphrates running along its eastern frontier for so consi-

derable a distance from north to south, favoured this notion. Herodotus reckons *Asia Minor* among one of his *Actæ*. [See *ACTIUM* and *ASIA*.] From the coast of mountainous Cilicia to Sinope on the Euxine, he assigned a breadth of only five days' journey for a stout pedestrian. The real breadth of the narrowest part, which is considerably less than the true breadth of the line described by Herodotus, is somewhat more than 300 English miles, reckoning from the gulf of Issus to Fatsah, west of Cerasus, on the Black Sea. The width assigned by Eratosthenes, 3000 stadia, is very near the truth: Pliny, with his usual inaccuracy, gives it 200 Roman miles, about 100 short of the mark. D'Anville, in his *Map of Asia Minor*, made the Isthmus too narrow by a whole degree, or about seventy miles, which consequently led to error in his positions all through the interior of the country, and compelled him to make amends for this loss of space by pushing the limits of the peninsula too far to the east. (See Major Rennell's *Treatise on the Comparative Geography of Western Asia*, vol. i.) Major Rennell says that the peninsula of *Asia Minor* is about one-sixteenth less than the peninsula including Spain and Portugal: the eastern limit of *Asia Minor*, adopted by Major Rennell, is the line of 300 miles between the Gulf of Issus and the Black Sea.

Asia Minor was known to the later Greeks under the divisions of *Mysia*, *Lydia*, and *Caria*, occupying the western shores. Those of *Lycia*, *Pamphylia* with *Pisidia*, and *Cilicia*, to which *Lycaonia* was sometimes added, bounded it to the south; and on the north coast were *Bithynia*, *Paphlagonia*, and *Pontus*. The elevated plains of the interior presented to the east *Cappadocia*, extending over the mountains to the borders of the Euphrates; and *Phrygia* on the west, bounded towards the sea by *Mysia*, *Lydia*, and *Caria*. Adjoining these two great internal divisions to the north was *Galatia*, a division of later date than the rest, having originated in the Gallic invasion, B.C. 278. Its chief town was *Ancyra*. This province in fact arose from the dismemberment of parts of *Phrygia* and *Cappadocia*. The Greeks established colonies and built towns on all the three coasts of the Peninsula, but their occupation was most complete and continuous on the west side. Here we find, lying from north to south, the districts of *Æolis*, *Ionian*, and the little *Dorian* confederation in the S.W. angle of *Caria*. The several ancient political divisions are briefly noticed under the separate heads.

By the Romans this country was sometimes divided into *Asia within* and *Asia beyond Taurus*. Our imperfect knowledge of the country prevents us from placing any reliance upon statements of the divisions in existence under the present government. The Turks are represented to have parcelled out this territory into pashalics under seven general heads, confounding all the ancient distinctions. This account is taken from Malte Brun, who makes the statement on the authority of a Turkish geographer, a MS. translation of whose work, without date, is preserved in the Royal Library at Paris. The following are his divisions:—1. the Pashalic of *Anadoubly*, (*Anatolia*), extending over *Mysia*, *Lydia*, *Phrygia* Proper, *Lycia*, *Caria*, *Pamphylia*, *Pisidia*, the larger part of *Galatia*, and *Paphlagonia*; 2. the Pashalic of *Siwas*, (*Sebaste*), containing Eastern *Galatia*, and the upper part of *Pontus*; 3. the Pashalic of *Tarabozan*, (*Trebisond*), being *Cappadocian Pontus* and southern *Colchis*. Hadgi-Khalfah, the geographer, mentioned above, considers this pashalic as a dependence on *Armenia*. 4. The Pashalic of *Konieh*, (*Iconium*), containing Central and Western *Cappadocia*, *Lycaonia*, and *Isauria*; 5. the Pashalic of *Merasche*, (*Merash*), bordering on *Syria*, and containing *Commagene*, *Cataonia*, and part of *Cilicia*; 6. the Pashalic of *Adana*, being *Cilicia* Proper; 7. the *Mousselimlik* of *Cyprus*, held of the Grand Vizier, being an appanage of his office. The work in question is of ancient date, and no mention is made in it of the feudatory possessions of *Chapwan Oglu* and *Kara Osman Oglu*, so long the delight of their people, and the protectors of European travellers. Before the Greek revolution, important changes had occurred in the general administration of *Anatolia*. These great feudatories had been swept from their possessions by the Sultan, jealous at the success and vigour of their sway; and since that event, *Smyrna* and *Ionian* have been elevated into a pashalic. The following divisions are given by Balbi as those now constituting the divisions or eyalets of *Asia Minor*: *Anadoli*, *Adana*, *Karamania*, *Marach*, *Sivas*, and *Trebizond*.

Asia Minor, though the seat of early civilization, and still containing numerous traces of former prosperity, is a country very little known. The southern coast was surveyed by Captain Beaufort, who commenced at Yedy Booroon or the Seven Capes, just to the west of the river Xanthus in Lycia, in July 1811. The survey was continued along the coast to Ayas, (*Ægæ*) in the gulf of Scanderoon, and was unfortunately interrupted before that interesting bay could be examined, owing to the commanding officer being disabled by a treacherous assault of some vagabonds from the mountains. The west coast from the entrance of the Dardanelles to the point where Captain Beaufort's operations commenced is not yet so accurately laid down; but Captain Copeland, who has finished his survey of the coast of Macedonia, is now engaged on the west coast of Asia Minor, and, perhaps, may have an opportunity of peeping into the Dardanelles. There is a Spanish survey of the Dardanelles, of the sea of Marmara, and the channel of Constantinople, with some additions made by the Hydrographical Office of the British Admiralty; and the north coast of Asia Minor is laid down from French and Russian surveys, (the French survey by Captain Gauttier,) but not with that minuteness that is still desirable.

The southern coast, as far as it was surveyed by Captain Beaufort, presents an irregular outline, formed by two huge semicircular sweeps presenting their convex side to the sea, and by two other bold sweeps with their convex side running into the land. There is, however, no deep gulf or bay with the exception of that of Issus or Scanderoon, which runs up between Asia Minor and Syria. Few coasts present so bold a front to the sea. From the gulf of Glaucus to the extensive plain which opens behind Adalia, an almost uninterrupted mass of lofty mountains presses near the shore, and sometimes, as at the Climax, forms the immediate boundary of the waves. From the mouth of the Eurymedon to the peninsula of Cape Cavaliere there is a series of bold promontories; and in some parts bare rocky hills form the coast, as between Selinty and Anamour, backed by lofty mountains. Near the eastern extremity of the coast surveyed, the wide plains of the level Cilicia open on the sea, commencing near the city of Soli, and extending some distance along the N.W. coast of the Gulf of Issus. There are very few and inconsiderable islands on this coast, and the same is true of the northern coast: the reason will be apparent when we come to consider the direction of the principal mountain-ranges of the peninsula.

The western coast of the peninsula presents as jagged and irregular an outline as almost any coast in the world, and in many respects very much resembles the opposite shore of Greece. Deep bays with bold projecting peninsulas, and islands which are continuations of the adjacent promontories of the main-land, characterize this coast. Though it has few rivers with a large volume of water, the courses of the Mæander, the Caystrus, the Hermus, and the Caicus, which exceed those of the southern slope, (with the exception, perhaps, of the rivers which water the eastern Cilician plain,) and their general direction from west to east, show that they lie in the longitudinal valleys, whose mountain barriers extend to the coast of the Archipelago. The channel of the Dardanelles, the ancient Hellespontus, separates Europe from Asia by a strait about forty miles long, and at its narrowest part not more than one mile broad. The wider opening of the Propontis or Sea of Marmara, about 140 miles long, (taking the longest line,) and 45 broad in the widest part, is succeeded by the narrow channel of Constantinople, (14 miles long,) which unites the Sea of Marmara and the Black Sea. The coast of the Black Sea presents no very deep indentations or bays; and though the mountains are never very far removed from the shore, a considerable extent of coast from the entrance of the Black Sea along the shore of Bithynia is comparatively low; but as we advance eastward, we find the high lands near the shore, and the depth of water as marked on the charts very great. From Cape Karempi (Carambis) for some distance eastward, the coast is marked as high; and from the neighbourhood of Sinub (Sinope) as far as the town of Samsun (Amisus) it has the same general character. From the mouth of the Yeshil Ernak to Cape Yasoun, a distance of 70 miles, the coast is low; the remainder, as far as Trebizond, is more elevated, though as far as we know, not lined with such high cliffs and rocks as characterize some other parts of the coast.

As the great mountain ranges on the north and south

sides of the peninsula have a general direction corresponding to that of the coasts, and as the rivers on all the three sides of the peninsula enter the sea at right angles to the general coast line, it follows that the valleys of the streams that enter the sea on the north and south must be of a very different character from those of the Mæander and the Hermus, which enter the sea on the west. But few streams on the southern coast traverse any considerable ranges of hills, and, perhaps, none penetrate from the north side of the great barrier of Taurus to the Mediterranean. The Pyramus (Jihoon) passes by a deep cleft through the mountain barrier (Strabo calls it Taurus: *Casaub.* p. 536) which unites the range of Amanus with the range of Taurus, after it has taken its great turn to the north. According to the description of Strabo, an eye-witness, this must be one of the most magnificent mountain-passes in the world. On the north side some considerable rivers intersect the mountain-chains, forming deep gorges and narrow transverse valleys that give this country quite a different appearance from that of the western side of the peninsula. Such is the gorge in which Amasia, the birth-place of Strabo, stands, on the Iris (Yeshil Ernak).

The grand characteristic features of the geography of Asia Minor are the vast ranges of mountains which traverse it; two chains detached from the plateau of Armenia, one, the more southern, the Anti-Taurus of the ancients, the other, the Paryadres, known by the modern name of Tcheldir, or Keldir, unite probably near Kesariah, in the knot of Mount Argæus, now called Argis-Dagh. Covered on its summit by perpetual snows, this circumstance must determine in so low a latitude the elevation of this mountain to be from 9,000 to 10,000 feet. The southern chain, which is, in fact, the Taurus, in its most definite sense, detaching itself from Mount Argæus and the Anti-Taurus, first takes a southerly direction to the neighbourhood where the Pylæ Ciliciæ (the mountain pass of Cilicia) are situated. It then runs in a general westerly direction, but in an irregular line like the coast; and, as far as we can form a conjecture, terminates in the peninsulas of Cnidus and Halicarnassus, forming the southern boundary of the valley of the Mæander. The highest part of the Taurus seems, however, to take a southern course along the west side of the valley of Adalia; and its bold summits press close on the whole coast of the ancient Lycia, and perhaps nearly fill the interior. Strabo traces the range of Taurus as far as the coast of the mainland opposite to Rhodes. The mountain above Phaselis, called Takhtalu, the ancient Solyma, is 7800 feet high; but some summits in the interior must be still higher, for while Takhtalu, in August, had but a few streaks of snow on its peak, 'many of the distant mountains in the interior were completely white for a fourth part of the way down their sides.' (Beaufort's *Karamania.*)

This range of Taurus is the great southern wall which is the boundary of the high lands in the interior: its steep side is on the south. A branch, the Sultan-Dagh, detaches itself from the main mass in about 37° 40' N. lat., and near the lake of Egerder: it turns to the N. and N.W., where it is the Paroreius of Strabo, and continuing a westerly course, forms by one branch the northern boundary of the Mæander valley, under the ancient name of Messogis. The range of Tmolus, which lies between the Hermus and Caystrus, appears to detach itself from the Messogis at the head of the valley of the Caystrus. Along the northern part of the peninsula we find mountain ranges, of considerable elevation, extending eastward from the Hellespont into Armenia. Though there is doubtless more than one range, or, at least, smaller ranges bordering on the chief one, and running in this direction, still we trace the great mountain line from west to east under the ancient names of Ida and Temnon in Mysia, Olympus in the neighbourhood of Brusa, and eastwards, where the Sangarius makes its way through it. As the range approaches the Halys it had the name of Olgassys, now Ulguz-Dagh. Strabo appears to give the name of Olgassys to a parallel range farther north than the continuous chain of the Olympus, which is the Olgassys of Ptolemy, and runs in the direction from Osmanjik to Amasia. From Amasia the range is continued to Trebizond, and is consequently, during the greater part of its course, at some distance from the sea, between which and the main range there are plains and hills, but no high mountains. This range east of Amasia is entirely omitted in some maps.

Major Rennell considers that the northern and southern

ranges are connected by a western range, 'the ridge named in modern geography Morad, which connects by an oblique course from N.W. to S.E. Mount Olympus with Taurus, and at the same time separates the waters of the Sangarius from those of the Mæander and Hermus.' But this western range, if we are to understand by it a continuous chain, appears not to exist. The interior of Asia Minor between the great southern wall and the northern barrier which we have described, is, no doubt, intersected by numerous chains, which, however, have in general a westerly direction, though they are no doubt often connected by offsets in a transverse direction. The Morad of Major Rennell can be considered as nothing more than the general line, along which we may trace the decline of the central plateaus towards the west; and the high points in it would appear to belong to the central mountains which prolong their course on a base of less elevation to terminate in the promontories and headlands of the western shore. The mountain *Tamoudj*, seen by various travellers from Olympus in a southerly direction, is apparently a knot formed by the angular junction of the western mass of Temnon with the more eastern system of Olympus.

The centre of Asia Minor is an immense plateau supported by the ranges of mountains which we have described. Part of it is drained by the rivers that flow into the Black Sea; but an extensive tract, bounded by the great barrier of Taurus to the south, is covered with salt marshes, lakes, and rivers, possessing no visible outlet. This plateau is about 250 miles long from N. and E. to S. and W., and 150 miles broad. The chain of lakes is described as extending from the neighbourhood of Synnada (38° 50' N. lat., 31° E. long.) to the Tyanitis, which lies at the foot of the Cilician Taurus, at the point where it turns to the north. In rainy seasons these lakes overflow, and, Leake says, would entirely submerge 200 miles of land, were it not for the ridges that traverse the plains and separate them into basins. He further states, 'that these basins form themselves into three principal recipients, having no communication, unless it be in most extraordinary seasons.' These are, 1. Kara-Hissar and Ak-Shehr; 2. that of Ilgún and Ladik; 3. that of Konieh, receiving the overflowing of Sidyshehr and Beyshehr; 4. the basin lying between the Cilician Taurus on the south-east, and the opposite Cappadocian mountains on the north-west now called Hassan-Dagh. To these we may add the basin or basins west of the Sultan-Dagh range, the Paroreius of Strabo, which contain the large lakes of Egerder, and Burdoor (the antient Ascania, which is very salt), and numerous other small lakes. Under any other government these inundations would produce most abundant harvests; but they now run nearly to waste in watering pastures. The salt lake of Tuzla, the Tatta of Strabo, is one of the most curious features of Asia Minor; it is 30 miles in length, and furnishes with that useful article a vast tract of country. Strabo says, that anything immersed was soon covered by the saline incrustations, and birds were unable to fly if they dipped their wings into it. Leake tells us, 'that Sultan Murad IV. made a causeway across the lake, on the occasion of his army marching to take Bagdad from the Persians.' Consequently it must be extremely shallow, and subject to excessive evaporation during the summer and autumn heats. The salt lakes of this high plateau, which borders on the great range of Taurus, are found at intervals from the meridian of 30° to beyond 34°, and on both sides of the parallel of 38° for, perhaps, sixty or seventy miles. They appear to belong to the basins of the high lands, which admit no outlet. The formation of the elevated regions of Asia Minor was known to Strabo, who being a native of the peninsula and personally acquainted with many parts, might have left us a description more complete than any modern has had the opportunity of making, if accuracy of detail and of observation had always characterised his writings. But exactness of geographical description is, from the nature of the subject, not easily attainable, and appears still to wait for improvement from more exact observation and a better nomenclature. 'The mountain plains (*óρονέδια*) of Lycæonia,' says Strabo (p. 568), 'are cold, without trees, and serve as pasture for the wild ass.'

The rivers of Asia Minor have more celebrity than importance. The most considerable flow into the Black Sea. The Halys, now the Kizil-Ermak, is described as taking its rise by two branches in the higher ranges of the Taurus, in Cappadocia. These two main branches, after flowing through more than three degrees of longitude, unite about 39° 10' N. lat. from which point the course of the river

northward is exceedingly irregular. It falls into the Black Sea by one mouth, according to a French authority, at the boundary of Pontus and Paphlagonia. Tournefort describes it to be at its mouth about the width of the Seine at Paris. The whole course is probably not less than 400 miles. The Halys is the most western of the peninsular rivers which flow from the highest level of the interior; and as in the case of the large rivers of this portion of Asia Minor, its numerous branches unite before it descends to the lowest level, through which it appears to flow in a single channel. Its upper streams run in longitudinal valleys, and, we believe, should be represented differently from what they are in our common maps: this will be briefly discussed under the head of HALYS. The Halys is the largest river of Asia Minor; it formed once the boundary between the Lydian and the Median empires, and was considered by the early Greeks as a kind of natural dividing line of the peninsula. It might, perhaps, seem fanciful to derive its name from the Greek word for salt, (*ἅλς*; see Strabo, 546,) but we can hardly help believing that the name is descriptive, and was first given by the Greeks to its upper waters which border on the salt plains. It runs near salt tracts also in the middle part of its course. The modern Turkish name, Kizil-Ermak, means the Red River, but its true name is said to be *Aito-su*.

The Iris, now the Yeshil-Ermak, rises probably on the north side of the Paryadres, but its remotest sources are still doubtful. It runs past Tocat, and thence in a general north direction in a deep valley to Amasiah, the birth-place of Strabo. A few miles below Amasiah it is joined by the river of Kara Hissar, the Lycus of Strabo: the united stream flows through a lower country and enters the Black Sea about 15 miles east of Samsun (Amisus). The plain of Themiscyra, the fabled abode of the Amazons, was also watered by the Thermodon, now the Tarmeh; its origin and its course are not well known, but its length is abridged in some maps most marvellously and incorrectly. West of the Halys, the Parthenius or Barten, once the boundary of Bithynia and Paphlagonia in the lower part of its course, does not appear to traverse the great mountain barrier of the northern side of the peninsula. Its outlet is a little to the west of the antient Amastris.

The Sangarius, now the Sakaria, is a large river. It is said to be formed by two chief branches: the Ailak, or S.E. branch is formed by various streams, one of which is the river of Angora. The Ailak joins the S.W. branch, the antient Thymbrius, about 39° 50' N. lat. 31° E. long., and taking first a N.W. and then a N. course, flows into the Euxine through a part of the great 'Sea of Trees,' which runs east towards Boli. The Sangarius with the Halys and the Iris are probably the only three rivers between Trebizond and the entrance of the Dardanelles whose sources are in the high central plateaus, and whose courses traverse the northern mountain boundary of the high lands. The other streams that flow into the Euxine are almost countless in number, but their sources are in the lower and subordinate parallel ranges that lie to the north of the Olympus and its eastern prolongation, and consequently their courses are short and their volume of water inconsiderable. The streams which enter the sea of Marmara from the range of Olympus and its western prolongation appear to us to be exaggerated in most maps.

The rivers that flow into the Archipelago have been already alluded to as running in valleys of a different character from those of the Euxine. The four chief rivers, going from north to south, are the Calicus, Hermus, Caystrus, and Mæander; they run through valleys almost unrivalled for beauty and fertility. Two of these, the Hermus and the Mæander, probably originate in the western extremity of the central plateaus, but the upper streams of the Mæander are by no means yet satisfactorily described.

The rivers of the southern coast have necessarily short courses, though the volume of water brought down from the mountains is sometimes very considerable, and carries with it such quantities of sand and small stones as to have produced apparently very considerable changes in the embouchures of these rivers. The Eurymedon, which is 420 feet wide at its mouth, has a curved bar across the entrance with only one foot water on it, though inside the bar there are fifteen. The Calycadnus, the modern Ghiuk Sooyoo, brings down a prodigious quantity of matter, which at the outlet of the stream being acted on by the current from the east, has formed a large projecting deposit to the west of the river's mouth. Between the mouth of the Cydnus and the

Sihoon (the ancient Sarus), which are near one another, similar changes have taken place.

The Pyramus rolls down a continued volume of sand and earth, and is described by Captain Beaufort of the width of only 490 feet at its mouth. Almost all the rivers of Asia Minor make these deposits; and bars and external banks being allowed to form, the character of the coast is often affected. In this way alterations occur in the relative positions of places, which puzzle geographers in their attempts to reconcile differences.

In the survey of Captain Beaufort, we have every evidence of the former grandeur of this southern country, of the extent and magnificence of its cities, and of the number and excellence of its bays and harbours. So changed and degraded are its people in these days, that their existence now presents only a scene of listless inactivity. During the winter they reside on the coast; in summer many of them retire to the mountains. They frequently lead a course of lawless violence in open opposition to the Porte, and are described as especially suspicious and inhospitable to Europeans.

A most remarkable feature of Asia Minor is its fresh and salt water lakes. The whole country being formed by parallel ranges between the Mediterranean and the opposite Euxine, and these being often connected by transverse chains, cut up the country into an immense number of longitudinal valleys, deep gorges, high plateaus, and lower basins. The salt lakes, as we have remarked, appear to belong to the higher levels of the south, the centre, and the south-east. Bithynia, the region of the fresh-water lakes, contains five large and beautiful lakes besides smaller pieces of water; of these the Ascanius (to be distinguished from a southern lake of the same name already mentioned) is the most beautiful: at its eastern extremity stands Nicæa, or Isnik, celebrated in ecclesiastical history for its great council.

A few remarks are necessary on the existing roads in the interior of Asia Minor; but no road in the European acceptance of the term has ever existed of their own construction in the empire of the Turks. Asia Minor still presents remains of the Roman lines of communication; and of the Roman bridges many yet are in use. Relays of post-horses are still maintained by the Turks at distant intervals. They are principally stationed at the large towns of the leading routes. The most frequented road is that from Smyrna to Constantinople, and the only one by which there is a regular communication, except by caravans. Important as is the trade between these great cities and the rest of Europe, this correspondence takes place but twice a month, and is managed by the Austrian mission and consulate, which, as well as the Russian, despatch, at stated periods, a post to the European capitals. The Porte keeps in constant employment a corps of Tatar couriers, by means of whom they make all their communications. On a smaller scale every pasha has a similar establishment. The route from Smyrna to Constantinople passes over the rugged tops of the Sipylus to Magnesia at the foot of the mountains. Proceeding across the valley of the Hermus, the Tatars pass within sight of Thyatira to the east. This is a considerable place, and contains a large Greek population. Its size is about that of Magnesia. Much cotton is grown in the neighbourhood. The valley of the Caicus is then crossed; the direction of the course being constantly north with a slight bearing eastward. The country displays a remarkably bold outline and every capability of fertility, though little favoured by the hand of man. The land journey terminates at Moukalith, whence the traveller embarks on the Macestus, or at Moudania, the port of Brusa, according to the circumstances of the weather. This journey is never performed wholly by land, except during the prevalence of the northerly gales in winter, as the distance is increased a third by proceeding round the Gulph of Nicomedia. In Turkey, the traveller is frequently astonished amidst the general desolation at the extreme care manifested in keeping up the tanks and fountains, stationed at convenient distances. The burial places are always planted with cypresses, and frequently exhibit more of care and art than the habitations of the living. Both the khans, where travellers are received, and the mosques, but too frequently betoken the ruined state of the country. No caravans travel from Smyrna to Constantinople, the sea being the cheapest mode of conveying goods.

Of the routes traversing Asia Minor from north to south, that from Constantinople to the southern pashalics proceeds from Moudania to Brusa, already mentioned, and by its beau-

tiful and fertile territory across the range of Olympus, to Kutaya, formerly Kotyæum on the Thymbrius, the residence of the beylerbey of Anatolia, the highest authority of Asia Minor. The city stands at the foot of the Poorsac-dagh, in a cluster of mountains, bounded by a fertile plain to the south. It is a large place, and though not so flourishing as formerly, still contains 50,000 or 60,000 people, of whom 10,000 are Armenians carrying on a profitable trade, and about half that number Greeks. Kinneir, between Kutaya and Konieh, visited AFUM-KARA-HISSAR. Another route, entirely by land, leads from Constantinople to Konieh, through Ismik (Nicæa) and Eski-Shehr, (Dorylæum) a town of little importance, watered by the Thymbrius, and now, as formerly, known for its natural hot baths. The two lines join at Kutaya. Konieh, the ancient Iconium, the seat of government of a pasha of three tails, was the residence of the sultans of the Seljukian dynasty. It contains about 30,000 inhabitants, and has little or no trade, the territory being much neglected. To the east are extensive marshes. The plain of Konieh is considered the largest in Asia Minor, and according to Leake, presents an uninterrupted level of the finest soil, quite uncultivated, except in the immediate neighbourhood of some widely-dispersed villages. 'Another characteristic of these Asiatic plains,' he says, 'is the exactness of the levels, and the peculiarity of their extending without any previous slope to the foot of the mountains, which rise from them like lofty islands out of the surface of the ocean.' Proceeding to the chain of Taurus, Leake passed Karamân, a poor, and greatly reduced town, and ascended the mountains in the direction of Mout (Claudiopolis), a place wretched in itself, with a yet more wretched population, though governed by a pasha of two tails. It appeared to this traveller, that the highest mountain near the pass must have a height of between 6000 and 7000 feet. Thence the route led down to Gulnar, or Celenderis, in Cilicia Tracheia.

Another route, advancing in the same direction from the Bosphorus, at Eski-shehr pursues an exact eastern course, and reaches Angora, through a country everywhere infested with tribes of Turcomans. Angora (Ancyra) is the capital of Galatia. It is situated on an elevated plain, famed for its fruit, and produces goat-hair nearly as fine as silk, which is made into camlet. Angora has fallen from its importance as a place of trade. Pococke, an old traveller, calls its population 100,000. Kinneir states it at 20,000. Both accounts may possibly have been true, for such a change is a probable consequence of the misery of Turkish rule. Kinneir tells us, that the valuable Angora goat is only to be found within the boundary of Wulli-khan, to the west, and the Halys, to the east. It immediately deteriorates on leaving this district. The territory to the S. E. of Angora, is covered with Turcoman encampments. These people pay no tribute to the Porte, which is without power to enforce it, or to rid the country of them. From Angora, Kinneir proceeded to Ooscat, the capital of Chapwan Oglu, then a place of importance, and of considerable population, but now probably, since the destruction of the family, in utter ruin. Hence a route leads past Kesariah to the celebrated pass of the Taurus, known to the ancients as the Pylæ Ciliciæ, where the Romans had a military station, to protect the position. But the regular road to these defiles from the Bosphorus, and the north-west of Asia Minor, is much more direct than by Kesariah. Having reached Angora, it proceeds in a course far to the west of the other line, and passes the great chain of Hassan-Dagh. The Cilician defiles are described as extremely difficult, ranging, according to Kinneir, for some distance at a width only of from 50 to 200 yards. The country, in descending to Tarsus, is cultivated, and produces wheat and barley. Here the Tatar couriers embark for Egypt and the coast of Syria. By the route leading entirely overland from Constantinople to Kesariah, by Iznikmîd, Angora, and Kir-Shehr, the great caravan, which is annually formed at Soutari, proceeds to the east for the purpose of taking the pilgrims of the capital to the birth-place and tomb of their prophet at Mecca and Medina. From Smyrna, two great trading lines proceed. The caravans frequenting the first, march in a direction due east to Allah-Shehr, (Philadelphia,) at the northern base of Tmolus. This town has a population of from 15,000 to 20,000. Hence they proceed by Afum-Kara-Hissar, to Konieh, carrying the manufactures of Europe and colonial produce into the heart of the country. From Philadelphia a route proceeds across the Ak-Dagh, or White Mountains

(the antient Messogis) to Adalia, on the Pamphylian sea. It passes by Hierapolis. The town is a mass of grand ruins; and Arundel tells us 'that the road up to it is at the eastern end a petrification, overlooking many green spots, once vineyards and gardens, separated by partitions of the same material.'

The other line of trade, direct south of Smyrna, crosses the valley of the Caystrus, and proceeds to Guzel-Hissar, the antient Tralles, a large and important place in the rich and fertile valley of the Mæander. Seated in such a district, this town could not fail to have a large population. Though subject to malaria in autumn, it is supposed to contain from 30,000 to 40,000 people. The trade consists chiefly of cotton, corn, and fruit. Thence the route proceeds to Melaso (Mylasa), famous for its produce of tobacco, amongst the best grown in Turkey. Taking a south-eastern direction here, this line ends at Patara in Lycia. Since the commencement of the Greek war, all the trade of the western and southern shores of Asia Minor has, of necessity, been conducted by the internal lines of communication; the sea having been literally swept by the cruisers and pirates of all the small vessels engaged in commerce. Other roads besides those mentioned have at various times been followed by traders and travellers. One route follows the valley of the Mæander, and continues along the north side of Taurus and through the lake countries to Konieh, which is a great central point towards which the routes leading to the Pylæ Cilicia necessarily tend. The route usually followed by travellers in going from Upper Persia or Armenia to Constantinople is, through Kara-Hissar, Tocat, Amasiah, Osmanjik, the forests west of Boli, (see Morier's *Travels*, p. 358,) across the Sangarius to Isnikmid, the antient Nicomedia, and thence to Scutari opposite Constantinople. The miseries of civil war and the dread of piracy being unknown on the shores of the Black Sea, they may be safely navigated by small vessels during more than six months of the year, and this facility of water-carriage bestows comparative prosperity on the north of Asia Minor.

No general description would convey a correct idea of the climate of Asia Minor, which presents probably more varieties than the peninsula of Spain and Portugal, with which we have compared it as to extent of surface. The comparison may be carried farther. In the numerous chains of lofty mountains which traverse them, in their high plateaus, and in the diversity of climate depending on the configuration of surface, there is a considerable resemblance between the two countries. The climate of both is also materially affected by the adjacent seas. The western shores of Asia Minor occupied by the Greek colonies, and known by the antient names of *Æolis* and *Ionia*, have been celebrated in all ages for their genial climate, and for the fertility of their valleys. The summers here, as generally through Asia Minor, are hot, and especially where the local situation does not allow the passage of a free current of air. Smyrna, owing to its situation, is never considered a healthy place. But even on the west coast severe cold is occasionally felt in winter, and neither the southern latitude nor the proximity of the *Ægean* can overcome the effect of the immense masses of high land which lie to the north in Europe, and to the east in Asia. The snowy peaks of Taurus continue even to the valley of the Mæander on the south side. The high plains of the interior are described as excessively cold in the winter season, though of their absolute elevation no certain statements appear to exist. The contrasts sometimes exhibited between the high regions and the adjacent lower valleys are such as characterise all countries which have a similar configuration of surface. 'At Siwas (Sebaste)', says Fontanier, 'the plague made no great progress, owing to the salubrity of the air, the proximity of the high mountains, and the elevation of the plateau on which the town stands. It is not so at Tocat, where the climate is much warmer, and where the cultivation of silk is carried on, but at Siwas they are obliged to import fruits and grapes, which will not grow there. Yet Tocat is only twenty hours' journey N.N.W. of Siwas, and though it lies in a deep valley of the Iris, is still considerably elevated above the shores of the Black Sea.'

The general effect of great elevation upon vegetable productions, even in southern latitudes, and the application of this principle to the physical structure of Asia Minor, were well known to Strabo. 'It is not at all surprising that the elevated and mountainous parts of these countries (he is speaking of Bactriana and Aria) are cold; for even in

southern climates mountains are cold, and in general all elevated surfaces are cold, even if they be plains. Accordingly the parts of Cappadocia on the Euxine are much farther north than those bordering on the Taurus: but Bagadania, a great plain which lies between Mount Argæus and Taurus, has hardly any fruit trees, though it is farther south than the borders of the Euxine by 3000 stadia. The vicinity of Sinope, Amisus, and Phanarœa, on the contrary, for the most part, allow the culture of the olive.' (Casaub. p. 73.) Strabo is mistaken about the 3000 stadia: the distance is not so much.

The northern shore of Asia Minor being exceedingly humid, parts of the mountain slope, from the edge of the high plains, are covered with magnificent forest trees of a great variety. The forests, stretching west from Boli, the great and almost inexhaustible source of supply to the Turkish navy, contain ash, elm, plane, poplar, larch, and beech, and some oaks of large size. (Morier, p. 359.) It is known to the Turks by the significant name of *Agatch Degnîs*, or Sea of Trees. Major Rennell assigns to this forest a length of 120 miles from west to east, and forty in breadth. The Sangarius passes through the western part of it, and the southern extends into the limits of the antient Galatia. Few parts of the world present, within the same limits, more striking contrasts than the 'sea of trees,' and the high levels of Lycæonia, which Strabo characterizes by the expressive terms of 'cold and bare.'

The coast of the Euxine and the valleys of the northern side of the peninsula are probably the finest part of Asia Minor. On the south, the immense mass of Taurus, rising like a wall, and in parts capped with eternal snow, leaves between the Mediterranean and its basis a comparatively narrow slip, and gives to the climate of the southern coast, combined with its geographical position, a character very different from that of the north side of the peninsula. The amount of rain is much less, and the summer heat of the coast is often excessive. Unlike the northern shore, which appears to be well supplied with ever-flowing rivulets, some portions of the Lycian shore, where the mountains press close on the sea, have no water from April to November, but what they can keep in reservoirs. The winter torrents cease with the rains. (Beaufort's *Karamania*.) The mountains of Karamania are in general well wooded, and Alexandria is mainly supplied with fuel from them. The timber of this coast, at least that near the shore, is mainly pine, but not in general of large dimensions. The mountains of Taurus contain a great variety of forest trees and shrubs. (Leake, 107.)

This country has, no doubt, at some period, been the seat of violent volcanic action, though perhaps not within the limits of authentic history. Volcanic products are abundant in the peninsula; and the Greek name *Κατακαυμένη* or burnt, which was applied to the district on the confines of Lydia and Phrygia, preserved, perhaps, the only historical record of those great physical revolutions. The western part of Asia Minor has also often experienced most destructive earthquakes, which have not only shaken the country from Sardes to the valley of the Mæander, but also the neighbouring island of Cos. (See Thucyd. viii. 41.) The country in which the earthquakes were most violent in antient times is the same which Strabo describes (p. 578) as the Burnt Region; of the country near the Mæander, he says in his usual obscure manner—'nearly the whole district of the Mæander is liable to earthquakes, and is burrowed under by channels full of fire and water as far as the interior of the country.' The whole western part of Asia Minor is full of thermal springs; they are found also at Brusa near the range of Olympus.

Of the rocks of this peninsula we possess but little information from travellers, though, perhaps, no country in the world would better repay the labours of a skilful observer. The great interior range of Taurus has never yet been examined, and our knowledge of the mountains generally of this peninsula, so rich in minerals and striking phenomena, is extremely scanty. From Captain Beaufort's survey of the southern coast, we learn that, from Patara to Cape Cavaliere, where the high rocks of the coast nearly terminate, a limestone formation shows itself at almost every point. The rivers also are loaded with calcareous sediment, and, like the streams of other countries where limestone prevails, are found unfit for drinking. The bold limestone cliffs are generally of a white colour; those of Cavaliere, of white marble, rise perpendicularly from the sea to the altitude of six and seven hundred feet, and show most singular contortions of strata, of which Captain

Beaufort has given a sketch. On the low parts of the shore a breccia, compounded of gravel, sand, and fragments of quartz cemented in a calcareous paste, sometimes presents a hard unyielding beach. The singular effects produced by the rapid deposition of calcareous matter are noticed by Captain Beaufort at a place on the coast called Laara, near the outlet of the river Catarrhactes, and he refers for similar instances to Chandler's description of the petrified cascade at Hierapolis in the valley of the Mæander.

The limestone formation seems to prevail in the high ranges on the north side of Asia Minor; and, according to M. Fontanier, the mountains which bound the east side of the valley of Siwas exhibit calcareous rocks at the base, covered on the south slope by enormous masses of gypsum, in which the rain, by infiltration, hollows out numerous caverns; the waters, loaded with sulphate of lime, run off along the calcareous mass beneath, and, forming a lake in the plain of Siwas, discharge the discoloured streams into the hitherto pure waters of the Kizil Ernak. In the mountains on the route from Kara Hissar to Siwas this traveller observed, between Andras and Tchiflik, the limestone of the Pyrenees alternating with serpentine; above the older limestone he remarked a more recent formation containing pectens with radii four inches long (p. 138). Between Siwas and Tocat, we remark the prevalence of limestone, though other rocks appear also; and the same may be remarked of the neighbourhood of Amasia. In going on the west route from Amasia, Fontanier remarks between Marcivan and Haggi-Kevi 'a plain of granite': as the word granite is often rather vaguely used, and as the information does not go beyond what we have stated, it is difficult to know exactly what is meant. Malte-Brun's remark, 'that from the Sangarius to the Halys we meet with nothing but granite rocks,' is absurd, and contrary to well-known facts. In the neighbourhood of Tossia, west of the Halys, and on the route to Constantinople, Fontanier marks his 'secondary limestone and chalk.' The mountains above Boli, the antient Adrianopolis, which lies farther west on the same route, are of 'a white calcareous material, with veins of black, and susceptible of a fine polish.' (Fontanier.) In fact we may trace the limestones of Asia Minor from the neighbourhood of Trebizond to the island of Marmara, in the sea of the same name, which derives its denomination from its quarries of marble. There is no doubt that Asia Minor presents one of the most extensive deposits of calcareous matter in the world. The marble quarries of Synnada, from which the wealthy Romans imported large blocks to their capital, are in the very centre of the peninsula at the north-western extremity of the basins of the interior lakes.

Asia Minor abounds in mineral wealth, as we know both from antient writers and from its commerce at the present day. The Chalybes, in the north-east angle, near the coast, were known in the earliest ages as the workers of metals; and the same region is still the great mining district of the peninsula. But it is only in the mountains of the northern portions of the peninsula that we are acquainted with the working of mines; nor, as far as we know, do any writers speak of them in the great southern range of Taurus, a region that belongs to the terra incognita of the world. Copper is worked near Trebizond, Siwas, Niksar, Amasia, Samsoun on the Black Sea, and numerous other places. Fontanier mentions a mine also at Maden in Karamania. Lead in combination with silver is found at Gurcouth, Husseinabad and other places (Fontanier, p. 254); and lead not worked is said to be found near Kara Hissar, which stands on the great eastern branch of the antient Iris. Unieh on the coast east of Samsoun exports rock alum: in the time of Strabo the cinnabar mines of Olgassys were worked, though we believe they are now no longer known; and the gold sands of Pactolus washed down from the range of Tmolus once helped to fill the treasures of the Lydian kings.

The political history of Asia Minor forms a large chapter in the history of the world. Its position on the western frontier of Asia has rendered it the seat of numerous struggles for sovereignty; its extent of sea-coast at one epoch developed its maritime capabilities, and the diversified nature of its surface has in all ages saved many of its inhabitants from the dominion of the conqueror. Herodotus informs us that in his day (between B.C. 488 and 400) this peninsula contained thirty nations (ἔθνη), which attested the numerous revolutions it had already undergone.

Though there might not be thirty peoples essentially distinct in physical character and language, we can have no doubt that conquest and colonization had in the time of Herodotus given this country as varied a population as it now possesses. The Phrygians claimed the highest pretensions to antiquity of any of the inhabitants of Asia Minor; next to them the Lydians, under Cræsus, became the rulers of the country from the Ægean to the Halys, at that time the western boundary of the empire of the Medes. But before the Lydian kingdom attained any strength, Greek colonies from European Greece had occupied a large part of the western coast of the peninsula, and established themselves firmly along this seaboard. In course of time the colonies of this nation spread northward along the shores of the Euxine as far as Trapezus, and on the southern coast, though apparently at a later period, as far as the Gulf of Issus. Many of the Greek cities of the interior, whose fine remains we still admire, were not built till after the age of Alexander, and some of them received their greatest embellishment under the Roman emperors. But between the empire of the Lydians and Medes, and the establishment of Greek kingdoms by the successors of Alexander, Asia Minor, which had before been ravaged by barbarians from the east, had to endure for two centuries the yoke of the Persians. The dominion of this nation, originally of nomadic habits, in its form of government, and the unfavourable effects of its political system, very much resembled the Turkish sway in the days of its former vigour; and, indeed, in the present decline of the Turkish power, the parallel may still be continued. The Persians never reduced the mountain tribes of Taurus to obedience, as we see in the case of the Pisidians; nor was their government more than nominal over the tribes of the north-east parts, with whom we become acquainted in the *Anabasis* of Xenophon. Under the Roman dominion, the peninsula attained the most uniform and settled state, and no doubt also the most prosperous condition that it has ever yet enjoyed. The decline of that power, and the feeble sway of the eastern empire, laid open the country to new invasion from the east, and the Mussulmans began to establish themselves in some of the eastern parts of the peninsula, about B.C. 700. When the first crusaders, under Peter the Hermit, landed near Nicæa in 1096, they found the Turks in possession of this part of Asia, and separated from the capital of Alexis only by the waters of the Propontis and the Bosphorus. The Turks had then become numerous in Asia Minor, and the population must for some centuries have been gradually undergoing a change. The wild incursions of the crusaders scarcely left a trace behind them in the peninsula; nor could the invasion of the Tatars under Timur, which resulted in the victory of Angora over Bajazet in 1402, and the subsequent capture of Smyrna, produce any permanent effect, though the entrance of so numerous an army must have somewhat modified the population of Asia. The political condition of the country at the present day is as unsettled as ever it was; and within the last year we have seen an army march from the banks of the Nile to the neighbourhood of the Bosphorus, and the sultan of Constantinople, in alarm, call in the aid of Russian troops and French diplomacy to stop the progress of the Egyptian arms. The Porte has yielded the Pashalick of Adana, a large part of which is a fertile country, rich in timber, corresponding apparently to the antient Level Cilicia, and with it the command of the mountain-passes, which will henceforward probably be crossed by an invader whenever a convenient opportunity offers. On the north-eastern frontier, the Russian is become the neighbour of the sultan; and thus, both in the European and Asiatic continent, successful revolution on one side, and invasion on the other, have hemmed the once-dreaded Ottoman within much narrower limits.

The principal component parts of the population of Asia Minor at present are, in the towns and villages, Turks, Greeks, Armenians, and Jews. The population that does not belong to the towns is of a nomadic, and probably of a very mixed character; they are generally classed under the denomination of Turcomans, and are sometimes confounded with the Kurds, who are really a different people. It is not unlikely, however, that the Kurds have spread westward from the mountains of Curdistan proper, and have been mingled with Turks and Turcomans on the west side of the Euphrates as far as Siwas. (For further information on Asia Minor, see Rennel's *Geography of Western Asia, and his Map*; Leake's *Journal of a Tour in Asia Minor*, with

the numerous authorities referred to by both; Fontanier, *Voyages en Orient*.)

ANATO'LICO, a town of western Greece, or antient Ætolia. It is built on a rocky island in the midst of the lagoons, or salt-marshes, which form part of the gulf of Mesolonghi, 38° 40' N. lat. 21° 35' E. long. It surrendered in March, 1826, to the Egyptian troops under Ibrahim Pasha, and its capture, together with that of the islet of Vassiladi, which was the advanced post of Mesolonghi, contributed to the fall of the latter place, which happened in the following April. The inhabitants of Anatolico, about 2000 in number, were sent free to Arta, in Epirus, and were allowed to take with them such personal property as they could carry. Anatolico belongs now to the new kingdom of Greece. The fishermen of the lagoons of Anatolico use canoes, which they call *monoxyla*, (single pieces of wood,) formed of the hollow trunks of trees.

ANATOMY, from a Greek term (*ἀνατομή*), which literally signifies 'the separation of a thing into parts by cutting;' the term anatomy is used to signify, particularly, dissection, or knowledge acquired by dissection. Anatomy is at once an art and a science; an art, inasmuch as the pursuit of it requires skilful manipulation; and a science, inasmuch as certain general principles are deducible from it. The object of anatomy is to ascertain the structure of organized bodies. Of the two great kingdoms of nature, the inorganic and the organic, it comprehends the whole range of the latter. Like the organized kingdom itself, it forms two divisions, the one including the structure of plants—vegetable anatomy; the other the structure of animals—animal anatomy. Animal anatomy is divided into comparative and human; comparative anatomy includes an account of the structure of all classes of animals, excepting that of man; human anatomy is restricted to an account of the structure of man only. Human anatomy is subdivided into descriptive, general, and pathological. **DESCRIPTIVE** anatomy comprehends a description of all the various parts or organs of the human body, together with an account of their situation, connexions, and relations, as these circumstances exist in the natural and sound, or, as it is technically termed, the normal condition of the body. The human stomach, for example, is composed of a number of membranes, which are united in a particular manner; a number of blood-vessels which are derived from particular arterial trunks; a number of nerves which proceed from a particular portion of the brain and spinal cord; a number of absorbent vessels and so on: moreover, this organ is always placed in a particular cavity of the body, and is always found to have certain specific connexions or relations with other organs. The anatomy of the human stomach comprehends an account of all the particulars of this kind, which are uniformly found to concur in all human bodies in which the conformation is regular or natural; and so of every other organ of the body: and because such an exposition of the structure of the various organs includes a description of all the circumstances that relate to their organization, it is called *descriptive* anatomy.

After the study of the human body in this mode has been carried to a certain extent, with a certain degree of success, it necessarily gives origin to a second division of the science, that termed **GENERAL** anatomy. It is found, that many of the circumstances which belong to any one organ, belong at the same time to several organs; and that thus several individual circumstances are common to many organs. Of the membranes, for example, of which it has been stated that the stomach is composed, some are common to it and to the intestines, to the bladder, to the uterus, to the air-passages, and so on. In like manner with respect to any one of these membranes, when its structure is carefully examined, it is found that in many points its organization is exactly similar to that of all other membranes. This view extended leads to further important and interesting results. All the arteries of the body, whatever their situation, size, or office, are found to be composed essentially of the same substances, disposed in nearly the same order and form. All the veins have, in like manner, a structure essentially the same. All the absorbent vessels, all vessels of every kind, all the bones, muscles, and nerves, the whole external covering of the body or the skin, widely as these various structures differ from each other, present no material difference as far as regards the organization of each particular class. Hence various organs of the body are disposed into what are called common systems, and these com-

mon systems are said to consist of common substances or tissues. All the vessels, for example, are collected and arranged under one common class, called the vascular system: in like manner, all the bones are collected and arranged under another class, called the osseous system; all the muscles under another, called the muscular system; all the nerves under another, called the nervous system, and so on. The material that enters into the composition of each of these systems consists of a substance of a peculiar nature; but as this substance is more or less generally diffused over the whole body, entering as a constituent element into the various organs, it is termed a common substance, or tissue. What is termed the common cellular tissue, for example, is the substance of which all the membranes and vessels of the body are composed; the muscular tissue is the substance of which all the muscles are composed; the nervous tissue is the substance of which all the nerves are composed: and thus, the structure of the body, analysed in this mode, innumerable and complex as the substances appear to be of which it consists, is ultimately reduced to a very few simple materials, by the combination and modification of which all the different animal substances are produced. That part of anatomy which displays those common substances, and which describes all that relates to these differences, analogies, combinations, and so on, is termed **GENERAL** Anatomy. Descriptive and general anatomy, then, include an account of the structure of the body as it exists in the state of health. But there is no organ of the body, and no tissue which enters into its composition, which is not subject to disease; in consequence of disease, the regular or natural structure of the component substances of the body becomes changed in a great variety of modes. That part of anatomy which displays these diseased or morbid changes, and which describes all the circumstances relating to them, is called **PATHOLOGICAL** or **MORBID** Anatomy. We may say then, that descriptive anatomy comprehends an account of all the parts or organs of the body as they exist in the state of health; general anatomy comprehends an account of all the separate substances of which those organs are composed, not as these substances exist combined in organs, but as they form distinct and peculiar substances; pathological anatomy comprehends an account of all the changes of structure produced by disease, whether in individual organs, or in the primitive or common substances of which these organs are composed.

It is obviously impossible to include in a single article a subject so wide as this. However concise the descriptions under each head might be, it would necessarily swell the account to such a length, as to be incompatible with the plan of the present work. We must, therefore, satisfy ourselves with referring to the separate heads under which the topics comprehended in this subject will be treated. In the mean time, we offer a few observations illustrative of the nature and value of the science of anatomy.

1. In the first place, anatomy is the basis of physiology. It is the object of anatomy to ascertain structure; it is the object of physiology to ascertain function. An organ is constructed in such a manner as to fit it to perform a certain action; the action cannot be understood unless the structure be known; and, often, the structure cannot be known without directly leading to a knowledge of the action. Until the art of anatomy began to be cultivated, the science of physiology was without existence. In proportion as anatomy has been practised, physiology has advanced.

2. In the second place, anatomy and physiology are the basis of the science of medicine. Disease, which it is the object of the physician to detect and to cure, is denoted by disordered function; disordered function cannot be understood without a knowledge of healthy function; healthy function cannot be understood without a knowledge of structure; and structure cannot be understood unless it be examined. The organs in which the most important functions have their seat are placed in the interior of the body, and are completely concealed from the view. There are no means of ascertaining their situation and connexion, much less their nature and operation, excepting that of inspecting the interior of the body. As the most important functions have their seat in organs which are placed in the interior of the body, so those internal organs are also the seats of the most frequent and fatal diseases. Consequently, an accurate acquaintance with the situation of these organs is indispensable in order to ascertain the seats of disease;

but as these organs are completely concealed from the view, it follows that their situation cannot be learnt without the study of anatomy. In several regions of the body, organs the most different in structure and function are placed close to each other. Diseases the most diversified, requiring not only not the same, but opposite treatment, may consequently exist in the same region of the body. Without the accurate discrimination of these diseases, it is often impossible to save life; but the discrimination of these diseases is absolutely impossible without that knowledge which the study of anatomy only can impart.

It has been justly observed, that one consideration, which shows in a striking light the importance of anatomical knowledge in leading to the detection of disease, is, that the seat of pain is often at a distance from the affected organ. In disease of the liver, pain is generally felt at the top of the right shoulder, because a nerve which goes to the liver is united with a nerve which supplies the shoulder. In disease of the lung, there is often no pain in the lung; but much uneasiness at the top of the windpipe. In disease of the hip-joint, there is often no pain in the hip, but severe pain at the knee. In all these cases, the attention is apt to be carried away from the real seat of the malady. Even at the present day, abundance of practitioners apply their remedies to the seat of the pain, wholly ignorant of the true seat of the disease: mistakes of this kind, often fatal, are inevitable without a knowledge of anatomy, while with that knowledge they are scarcely possible.

3. If the knowledge of anatomy be thus obviously important to the physician, it is still more manifest that it must be indispensable to the surgeon. Without a minute and exact knowledge of the structure, situation, and relation of organs, the surgeon cannot proceed a single step in the practice of his art without the most imminent peril. Many opportunities will occur in the course of this work of illustrating this truth; but perhaps the most striking proofs of it are afforded under the heads AMPUTATION, ANEURISM, HÆMORRHAGE, HERNIA, and LITHOTOMY. It has been justly stated, that no one can form an adequate conception but those who have witnessed it, of the confusion and terror occasioned by the sight of a human being from whose body the blood is gushing in torrents, and which none of the spectators are able to relieve. In all such cases, there is one thing proper to be done, the prompt performance of which is generally as certainly successful, as the neglect of it is inevitably fatal. It is impossible to conceive a more terrible situation than that of a medical man who knows not what to do on such an emergency. But the ancient surgeons were constantly placed in this situation; and the dread inspired by it retarded the progress of surgery more than all other causes put together. Not only were they prevented through terror from interfering with the most painful and destructive diseases which experience has proved to be capable of safe and easy removal, but in general they were afraid to cut even the most trivial tumour. They never thought of amputating until the limb had mortified, and the dead had separated from the living parts; and being ignorant of the means of stopping hæmorrhage, they were afraid to cut into the living flesh. But surgeons now know that there is one simple and effectual means of stopping hæmorrhage, namely, compression of the bleeding vessel. If pressure be made on the trunk of an artery, though blood be flowing from a thousand branches given off from it, the bleeding will immediately cease. Should the situation of the artery be such as to allow of effectual external pressure, nothing further is requisite; the pressure being applied, the bleeding is stanchied at once: should the situation of the vessel place it beyond the reach of external pressure, it is necessary to cut down upon it, and to secure it by the application of a ligature. Paré may be pardoned for supposing that he was led to the discovery of this invaluable remedy by the inspiration of the Deity. By means of it the most formidable operations may be undertaken with the utmost confidence, because the wounded vessels can be secured the moment they are cut: by the same means, the most frightful hæmorrhages may be effectually stopped; and even when the bleeding is so violent as to threaten immediate death, it may often be averted by the simple expedient of placing the finger upon the wounded vessel until there is time to tie it. But it is obvious that none of these expedients can be employed, and that these bleedings can neither be checked at the moment, nor permanently stopped, without such a knowledge of the course of the trunks and

branches of vessels, as can be acquired only by the study of anatomy.

The importance of pathological or morbid anatomy will be readily understood. What are called symptoms are signs of disordered functions; disordered functions are the consequences of irregular or diseased actions; irregular or diseased actions, after they have continued for a certain time, produce a change in the structure of the organs in which they have their seat. Certain disordered actions produce certain specific changes, modified indeed by a great variety of circumstances, which to a considerable extent are ascertainable and ascertained. The medical practitioner, who has an opportunity of comparing the symptom or the external sign, which he observed during life, with the morbid change of structure visible on inspection of the diseased organ after death, learns with exactness what the external sign denotes, that is, what state of the internal organ it expresses. Moreover, the external sign may not have been obtrusive, and yet it may have been present. It is to this comparison of the symptoms of disease during life, with the diseased changes of structure visible in the organs after death, constituting morbid anatomy, that we owe all the exact knowledge of disease which is at present possessed. There is not a single internal malady, the precise nature of which is now known, which has not been brought to light by morbid anatomy. The diseases, the precise nature of which still remains undiscovered, are those, the seats of which there have been few opportunities of inspecting after death, or in which the morbid changes produced in the organs are so slight or transient as hitherto to have eluded detection. Nor is there any probable means by which the true nature of such diseases can ever become better known than that of increasing the facilities of examining the condition of the organs immediately after death. An effectual remedy for a disease may not indeed be discovered when the exact nature of it is ascertained; but the discovery of the exact nature of a disease puts the physician in the right path in searching after the cure, and at all events teaches him what will be useless, and what mischievous. Hence a clearer apprehension of the nature of a disease has always preceded an improved treatment of it. If the plan of the present work admitted of the requisite details, it would be instructive to show how uniformly every exact and certain method of cure has followed and been founded upon that knowledge of disease which has been brought to light by the inspection of the organs after death. Compare, for example, the knowledge which enlightened physicians now have of fever, and the success which attends their treatment of it, with the darkness which rested on this malady, and the inertness or mischievousness of the remedies employed in it only a few years ago. A physician who understands fever, as far as the nature of this malady has been actually elucidated, can tell at the bedside of the sick with astonishing accuracy what internal organs are in a state of diseased action; what the kind of diseased action is in each; what the probable progress of it will be, that is, what morbid change of structure or organic disease it is its natural tendency to produce, and must inevitably produce, if it be allowed to hold on its course without being checked. To this extent his knowledge places the physician in the position in which he would be if the body of his patient were transparent, and he could actually see the processes that are going on in the internal organs. Having this knowledge, he knows with exactness what to attempt by the remedies which he employs: among numberless remedies he knows which to choose as being the best fitted to accomplish the end in view; his remedy being chosen, he knows the proper strength, the proper time, the proper frequency, in a word, the proper mode in which to exhibit it—that is, he knows how to exhibit it in the dose and form the best adapted to the actual condition of the organ which it is his object to relieve. He does not work in the dark. He has a definite purpose to accomplish, and an instrument of known power with which to compass his purpose. He even anticipates events; stops diseased processes at the very commencement; prevents morbid changes of structure, which, if once produced, too often prove incurable. The consequence is, that in a disease which above all others attacks the greatest number of the most important organs, his interference, as far as it has any influence, is conservative; he sees the impending danger and averts it; he protects the vital organs from a shock, which, but for him, would be fatal to them, while the very remedies employed by the ignorant practitioner increase that shock, and concur

with the disease in producing death. The great distinction between the enlightened and the ignorant physician is, that the former knows the state of the internal organs, and adapts his remedies to that state; while the latter knows nothing of the morbid processes that are going on, and prescribes for a fancy or a name. Compare, in like manner, the knowledge which enlightened physicians now have of the diseases of childhood, with the obscurity in which the diseases of this period of life were formerly involved. Take, as an example, the knowledge now possessed of the true nature of a malady which used to be exceedingly frequent and almost uniformly fatal among children, namely, water in the brain. A child screamed out suddenly whilst at play. A change was observed in the child's countenance. A physician was sent for in alarm. He found the child restless, irritable, flushed, constantly moving its head on the pillow, the skin hot, and the pulse quick. In a few days the pulse became slow and intermittent; the child from being in a state of constant restlessness, attended with an occasional sudden shriek, fell into stupor; vomiting was often superadded; and in a day or two more, the pulse having become again extremely rapid, the child expired in convulsions. Such is the brief history of the attack, progress, and termination of a malady which used to destroy hundreds of children, and often individual after individual of the same family. But was the history of the disease really thus brief, and its progress really thus rapid? On the contrary, the concurrence of symptoms was in fact exceedingly numerous, and their progress remarkably slow. The disease, at the point of time at which the history of it is here taken up, appeared to be seated solely in the head. The head, however, is the last part affected; the brain suffered entirely in consequence of its sympathy with other and distant organs. The disease commences in the abdomen. The child, long before it gave that ominous scream, had been fretful, hot, feverish, either without appetite or with voracious appetite, and those states of the appetite alternating with each other; either with a constipated or a relaxed state of the bowels, and those states also alternating with each other, the stools meantime being always unnatural, and the belly always tumid, hard, and oftentimes tender. These symptoms, because they did not lay the child prostrate upon its bed, were overlooked, or deemed of no consequence. But at last, from the total failure of all the means employed to save the child when the symptoms of brain disease came on, physicians began to take another view of the matter. They availed themselves of every opportunity they could obtain of inspecting the bodies of the children who died of this terrible malady. In the brain they found water indeed, but often only in very small quantity, and sometimes scarcely any; while there were always signs of inflammation, and, in general, signs of recent and active inflammation, in contradistinction to the signs which denote inflammation of a slow or chronic character. On looking farther, they found still more striking appearances of disease in the abdomen; appearances which denoted a disease of a slowly but constantly progressive character—the source of irritation to the whole system—an irritation not perceptibly yet uniformly increasing day by day. The real nature of the malady was now disclosed. The first appearances of disease were observed; the disease was attacked before it had time to be developed; the remedy was applied to the true seat of the malady, the abdomen, and not to the head, which as yet remained unaffected. Under early and judicious treatment, the head thus almost always remained unaffected; and now water of the brain in children is an exceedingly rare disease, hardly ever coming on but in neglected cases of disordered bowels—cases neglected on account of a more than ordinary degree of ignorance or inattention on the part of the mother or the nurse. This is an example of the manner in which an examination of the body, after death, has led to the detection of the true seat and nature of diseases; and it is but one example. A similar account might be given of almost every disease, the seat and nature of which are clearly and certainly understood.

It cannot be necessary to say more in illustration of the necessity of inspecting the body after death. The aversion to the dissection of the human body, which has hitherto prevailed in all ages and nations, is one among the many and grievous evils inflicted on man by superstition. It is the progress of civilization to change this aversion into respect and gratitude. A remarkable proof of this has been recently given

by the legislature of our own country. The British legislature had already acquired a bad notoriety among the civilized nations of Europe, for allowing the continuance of a barbarous practice of a barbarous age—for permitting the schools of anatomy to be supplied with subjects for dissection by the odious means of exhumation. At length Scotland first, and afterwards England, gave an appalling lesson to the government of the consequences that sometimes follow its own criminal indifference to the public good. When roused from this lethargy by the appearance of a new species of crime, the possibility of which had been foreseen, and even the probability of the perpetration of which had been predicted, the legislature began to make a provision for the cultivation of anatomy. A part of the public press, conducted by minds base and vulgar, and, therefore, ready to seize occasions for exciting kindred passions, endeavoured to raise a clamour among the people against the purpose of the government. The attempt was a signal failure. Few had been previously aware of the extension of just views on this subject among the mass of the people. There was a profound and universal impression of the usefulness, nay, the indispensable necessity, of anatomy. The destination of his own body to the purpose of public dissection by the philosopher,* was scarcely regarded with wonder by the mechanic or even the labourer, though it excited a feeling of deep respect in both. At this moment there is scarcely a woman in the lowest rank who would not be ashamed to refuse permission to her medical attendant to examine the dead body of her husband or child. We trust enough has been said to show to every woman, of whatever rank, that the institution of such an examination is the paramount duty of the medical man; and to teach her that the practitioner, who is not anxious to avail himself of this means of extending his information and correcting his errors, is either too ignorant to appreciate the value of his best guide in the doubtful and difficult path he has to tread, or too much absorbed in a money-getting art to practise his profession as a science. (See *Use of the Dead to the Living*, by Dr. Southwood Smith; *Lecture delivered over the Remains of Jeremy Bentham, Esq., in the Webb Street School of Anatomy and Medicine*, by the same Author; *Cooper's Dictionary of Practical Surgery*, Art. *Hæmorrhage*, &c.)

ANA'TOMY, COMPARATIVE. The term 'anatomy,' as we have seen in the preceding article, is chiefly applied to the science which determines the nature and relations of the various organs of the human body. A general term is here used in a restricted sense. On the other hand, when we would express the extension of the science of anatomy to the whole animal creation, we employ the general term with the addition of the word 'comparative.' This anomaly has doubtless proceeded from the circumstance that, till within a very recent period, the study of animal structure was almost exclusively confined to the human subject; and that even zoologists were contented with inquiring into the functions of animals, instead of determining the character of the organs which were connected with those functions. By the term comparative anatomy, then, we understand the science which conveys to us a knowledge of the differences in the structure and organization of the whole animal kingdom in all its classes, orders, and species.

It is evident that a science possessing such an extensive range must be exceedingly imperfect; especially when it is borne in mind that scarcely half a century has elapsed since the first attempts were made to simplify, by systematizing, its almost infinite details. It has, however, made sufficient progress, not only to have furnished the most important aids to the study of human anatomy and physiology, but to have supplied a secure and broad foundation for all zoological knowledge, both as regards existing and extinct races. As the basis of modern zoology, comparative anatomy presents a subject of the highest interest.

* By a will, dated as far back as the year 1769, Mr. Bentham, then a young man, left his body for public dissection. The reason at that time assigned for this is expressed in the following remarkable words:—'This my will and special request I make, not out of affectation of singularity, but to the intent and with the desire, that mankind may reap some small benefit in and by my decease, having hitherto had small opportunities to contribute thereto while living.' By a memorandum affixed to this document, it is clear that he had undergone his revision only two months before his death. (June 1822.) and that this part of it was again deliberately and solemnly confirmed. His body he devised to his physician, who was also his disciple and friend, who delivered a public lecture over it; the body was then used in the anatomical school in illustration of a course of lectures to students in anatomy; the skeleton and head, together with several of the organs, are preserved, the two former constituting one of the most beautiful preparations ever made.

Confining ourselves to this point of view, we shall endeavour to exhibit a few very general, and consequently imperfect, notions, of the principles of the science, as they are applied to a systematic arrangement of the animal kingdom.

In its connexion with zoology the universal knowledge of animal structure is properly called comparative; for it is the object of the science to establish those analogies in organization, which are to determine the separation of the vast number of beings that compose the animal kingdom, into classes, orders, and species. Without a knowledge of anatomical structure, at once the most minute and the most extensive, arbitrary distinctions would almost entirely prevail in the classification of species; and if we follow the history of systematic arrangement, we shall find that it began with the rudest and most empirical divisions, and did not assume the precision of a science until a knowledge of the organs, producing certain actions, took the place of the mere observation of the functions of animals without reference to their organs. The most ordinary observation of mankind would enable them to arrange animals into three great classes, according to their faculties of locomotion, and the general character of the place of their movements; and thus all beings would naturally be divided into those which swim in the water, those which fly in the air, and those which only walk on the earth. A more precise investigation would, however, show extreme differences between animals possessing the same sphere of locomotion. For instance, the great external differences of structure and habit would point out, amongst the inhabitants of the air, the necessity of forming two distinct groups, birds and insects; and the same degrees of difference, in terrestrial animals, would divide those which walk from those which creep. This observation of actions became connected with the observation of external organs: it was found that a large group of terrestrial beings might be separated from the rest of the animal world according to the number of their feet—from the birds who possess two feet, the insects who possess six, and the serpents who move without feet—by the name of quadruped, or four-footed. It was thus that the five great classes were established, of quadrupeds, birds, serpents, fishes, and insects.

When zoology assumed the character of a science, and ceased to be only a crude collection of isolated facts, (and this was not attempted before the labours of our own illustrious Ray,) it was gradually perceived that the most important class, that of quadrupeds, was a very unsatisfactory division. A cow was a quadruped, and so was a tortoise; but the one was covered with hair, the other with scales; the one produced its young fully formed and nourished them, the other laid eggs. For some time these contradictions were not reconciled, till science stepped in with the distinction of *viviparous* quadrupeds, and *oviparous* quadrupeds. In the first editions of the *Systema Naturæ*, Linnæus thus divided the animal kingdom: *viviparous* quadrupeds, birds, amphibia, (since changed for reptiles, and including serpents and oviparous quadrupeds,) fishes, insects, and worms. Nearly twenty years after the system of Linnæus had been given to the world, Brisson, a distinguished French naturalist, separated the cetaceous animals, or whales, from the fishes, and placed them next to the *viviparous* quadrupeds. He saw the anomaly of classing them with fishes, knowing that they suckled their young, and were in many other important characteristics of organization similar to the highest class in the animal kingdom. Linnæus acknowledged the importance of the distinction, and he even carried the principle farther than Brisson. He rejected the old division of quadruped, which excluded man at one extremity of the scale and the cetacea at the other;—and he adopted the name *mammalia*, which, expressing the mode in which the young of *viviparous* animals are nourished, makes this great distinction determine the first class of the animal creation.

Up to a certain point, and that reaching to the most important classes of animals, the system of Linnæus, thus amended, was strictly formed upon a view of the great characteristics of anatomical structure. The birds were separated from the *mammalia* by the evident distinction in their mode of producing and nourishing their young; although the two classes were similar in possessing the heart with two ventricles and two auricles, and having each warm and red blood: the amphibia (or reptiles), respiring by lungs, were separated from the fishes, breathing by gills; although the two classes had each a heart with one ventricle and one auricle, and the blood of each was cold and red. So far the

arrangement of Linnæus, with regard to the four highest classes of animals, has been preserved by Cuvier especially, and other naturalists, who have endeavoured strictly to arrange the animal kingdom with reference to the organization of every species. These four classes have been subsequently formed into one great family of *vertebrated* animals; and all the lower classes have been comprised in a second family of *invertebrated*.

When we come to the invertebrated division, we find that the two classes of Linnæus, the insects and the worms, very imperfectly expressed the great differences in the various groups into which so many hundreds and thousands of species might be resolved, when they were viewed with reference to their structure. Cuvier, the most distinguished comparative anatomist that has ever appeared, applied himself to the removal of these omissions and contradictions. He commenced his great task of classifying the invertebrated animals in 1795, and completed his system in 1812. The principle upon which he proceeded was that of seeking some larger and more comprehensive arrangement than that of classes; and he accordingly laid down the following general table of the animal kingdom:—

Four divisions. (<i>Embranchemens.</i>)	{	Vertebrated animals. (<i>Vertebres.</i>)
		Molluscous animals. (<i>Mollusques.</i>)
		Articulated animals. (<i>Articulés.</i>)
		Radiated animals. (<i>Rayonnés.</i>)

The first division, as we have before mentioned, comprehends the *mammalia*, birds, reptiles, and fishes of Linnæus. The second comprises those animals with shells that formed a portion of the worms of the old classification. The third includes all the insects of the same classification, and others that were formerly treated as worms; and the fourth, all the animals descending in the scale of being, including the remainder of the chaotic class of worms.

As the classification of Cuvier essentially depends upon organization, it may be desirable, in this place, to present a further Table of the System, in its extension to classes:—

Divisions.	Classes.	Number of Orders.	Examples.
First division.	1. MAMMALIA.	8	Man, Whale.
VERTEBRATA.	2. AVES.	6	Eagle, Duck.
Four classes.	3. REPTILIA.	4	Tortoise, Frog.
Twenty-seven orders.	4. PISCES.	9	Whiting, Lamprey
Second division.	1. CEPHALOPODA	1	Nautilus.
MOLLUSCA.	2. PTEROPODA.	1	Clio.
Six classes.	3. GASTROPODA.	9	Snail, Limpet.
Fifteen orders.	4. ACERBALA.	2	Oyster.
	5. BRACHIOPODA.	1	Lingula.
	6. CIRRHOPODA.	1	Barnacle.
Third division.	1. ANNELIDA.	3	Leech.
ARTICULATA.	2. CRUSTACEA.	7	Crab.
Four classes.	3. ARACHNIDA.	2	Spider.
Twenty-four orders.	4. INSECTA.	19	Beetle, Butterfly.
Fourth division.	1. ECHINODERMA.	2	Starfish.
RADIATA.	2. INTSTINA.	2	Tape-worm.
Five classes.	3. ACALEPHA.	2	Actinia.
Eleven orders.	4. POLYPI.	3	Spongo.
	5. INFUSORIA.	2	Monas.

In attempting to estimate the importance, and to point out the peculiar character, of a system of classification of the animal kingdom founded upon comparative anatomy, it will be impossible for us to enter into any minute details, interesting and instructive as they might be, which have reference to the distinctions of species; but it may be desirable to take a rapid view of the leading principles of the larger zoological arrangements.

The division of *vertebrated* animals is one which very happily marks a chain of affinities, connected with the gradual development of the highest organs and functions. The vertebral column is the necessary foundation of a skeleton: it supports the head; and the canal, which passes from one end of it to the other, incloses the common fasciculus of the nerves, which communicates with the nerves of the cranium. When we descend to the *invertebrated* animals, the skeleton no longer exists; the bony substance is altogether wanting, or is external, instead of internal; and the nervous system assumes an entirely different character, till it is gradually lost in the mere irritability of the lowest classes in the scale of animal life.

The organization of the first class of vertebrated animals,

ANIMALS,
arranged in Four Divisions, Nineteen Classes, and Seventy-seven Orders.

Digitized by Google

the mammifères, (*mammalia*), presents an articulated skeleton, generally much more perfect than that of the three other classes of the same division. The greater number have four articulated limbs, parts of the skeleton; and all have a diaphragm between the chest and the abdomen; a heart with two ventricles and two auricles; the blood red and warm; lungs filling the cavity of the chest, through which the blood passes in the course of its circulation. These are the only viviparous animals, properly speaking. The distinctions of *orders* amongst the class of mammalia is principally derived from the differences in the character of the limbs and the teeth. The first five orders possess the common character of having nails at the extremities (*Unguiculata*). These animals are therefore possessed, more or less, of the power of seizing upon objects. The first three orders have also the common character of possessing the three sorts of teeth; the canine, the incisive, and the molar. But the first order (*Bimana*, Man) is distinguished by having hands (that is, four fingers and an opposable thumb) upon the anterior extremities only; while the second (*Quadrumana*) have hands at the four extremities; and the third (*Carnivora*) have no opposable thumb upon either extremity. The fourth order (*Rodentia*) have no canine teeth; and the fifth (*Edentata*) no incisive. The hoofed mammalia (*Ungulata*) form two orders, the *Pachyderma*, and the *Ruminantia*. These are unfitted, from the character of their extremities, for seizing upon objects; they employ them only for locomotion. The eighth order (*Cetacea*) have no hind-limbs developed; and their fore-limbs are very short, and flattened into the form of fins, by which they are fitted for an existence in the water, although it is necessary for them to breathe above the surface.

The second class of vertebrated animals (*Birds*) have many parts of their organization similar to the mammalia. They have a heart with two ventricles and two auricles; warm blood; the cavity of the cranium wholly filled with the brain; and the trunk completely formed by ribs. But, on the other hand, they are oviparous; they have no diaphragm; and only the vertebræ of the neck and tail are moveable. The blood of this class passes through the lungs before its distribution to the other parts of the body; but the lungs are not free; they are attached to the ribs; and the external air passes through them in its way to cavities which are dispersed through the body. It is this circumstance which gives them the power of flying, that is, of using their anterior extremities, or wings, which stand in the place of the fore-arms and fore-legs of the mammalia.

The third class of vertebrated animals (*Reptiles*) offer, in their several orders, very considerable differences in their external characters, and their general habits—much more so than either of the preceding classes. Some have the fore-limbs which distinguish the mammalia and birds; others have very imperfect rudiments of them; and in others they are wholly wanting. But they all agree in having but one ventricle to the heart; in the coldness of their blood; and in their imperfect respiration, consequent upon a portion of the blood passing through the lungs.

The fourth class of vertebrated animals (*Fishes*) differ essentially from the preceding classes. The limbs have disappeared, and fins supply their place; the skeleton is, in many species, very incomplete. They breathe by gills, or branchial openings, instead of lungs, and they have consequently neither trachea, larynx, nor voice. The two great divisions of fishes are the bony and the cartilaginous. In some of the latter, the peculiar character derived from the skeleton of the vertebrated animals has almost disappeared.

When we arrive at the second great family of the animal kingdom, the Invertebrated—when we endeavour to classify that vast series of beings, which, possessing no vertebral column, or skeleton, gradually depart more and more from what we consider the type of the highest organization—we are astonished as much by the extreme differences of the organs, faculties, and habits, of particular classes, as by the unbounded variety of the species which those classes contain. It is in this department of the creation that zoologists have encountered the greatest difficulties, especially since they have founded their science upon the distinctions of anatomical structure. At every step of their knowledge they have felt how much they have yet to know. They have, however, established many of the most important principles and facts.

In all this great family of the invertebrated animals, the

supports of muscular action are not furnished by the internal parts of the body;—none of the classes or species respire by cellular lungs; none have a voice; and the nervous system, where any exists, has not its middle part inclosed in a cavity of bone. These are the great general distinctions between the vertebrated and invertebrated families. But the distinctions between the three divisions of the invertebrated animals, and the classes even of the same divisions, are so manifold and important, that we cannot attempt to furnish any adequate notion even of the general structure prevailing in each division, and must content ourselves with the most general outline.

The *Molluscos* division (*Mollusques*)—the fleshy bodies clothed with a shell—have a true circulation of the blood through arterial and venous vessels; they respire by branchiæ (gills); they have a brain, and possess a nervous system. Some have the organs of sight and hearing, while others appear to be limited to those of touch and taste. Some masticate their food, others can only swallow.

The *Articulated* division (*Articulés*), although possessing the common character which is indicated by their name, are so different in other important particulars of their organization, that we must briefly point out the leading peculiarities of each class. The *Annelida* have a long body, composed of rings; they are unprovided with articulated feet; they respire by branchiæ; have a system of circulation; and a long, knotted cord connected with the nervous system. The *Crustacea* have the body and the limbs articulated; the outer covering is bony, as their name implies; they have a system of circulation; and they respire by branchiæ. The *Arachnida* (often confounded with insects) respire by narrow tracheæ, and, not undergoing any transformations, have always articulated feet, and eyes in their head. The *Insects* undergo transformations; and have, in their perfect state, two eyes and two antennæ in the head, six articulated feet, and two tracheæ, which extend through all the body.

When we descend to the last division, the *Radiated*, (*Rayonnés*), we find that some of the organs which appear to be essential to life, as we see them developed in the preceding divisions, do not exist. The nervous system, whether consisting of a spinal cord, or a system of ganglions, totally disappears; the sexual system does not appear to exist; the head, properly so called, is no longer found; and the organ of sight is extinguished. It is unnecessary for us to trace the last degree in the scale of animal life, to that point when the animal kingdom appears to lose itself in the vegetable; and when the investigations of man, however skilfully conducted, are baffled by the minuteness, as well as the number, of the objects which he desires to examine and to register.

As it may be desirable to refer to the general arrangement by Cuvier of the Animal Kingdom, in Divisions, Classes, and Orders, we have given, in the opposite page, a Synoptical View, translated, with some additions, from the table drawn up by M. Achille Comte.

(See Cuvier, *Leçons d'Anatomie Comparée*; Cuvier, *Ossements Fossiles*; Blumenbach's *Manual*, by Lawrence and Coulson; Lamarck, *Philosophie Zoologique*; Geoffroy St. Hilaire, *Cours de l'Histoire Naturelle des Mammifères*; Home's *Lectures on Comparative Anatomy*.)

ANAXAGORAS, a philosopher of the Ionic school, born at Clazomenæ, one of the Greek towns of Ionia, in the first year of the seventieth Olympiad, or in B.C. 500, three years before the death of Pythagoras, and ten before the battle of Marathon. Born both to rank and wealth, he had leisure to apply himself to philosophy and astronomy, under the instructions of Anaximenes. In the twentieth year of his age (that of the battle of Salamis) he went to Athens, where he continued thirty years, engaged in the propagation of his philosophical opinions. He numbered among his hearers Pericles, Euripides, Socrates, Archelaus, who succeeded him as head of the school known by the name of Ionic, and some say, Democritus. He obtained the surname of *νοῦς* (the mind). It is said that he was the first who taught the distinction between mind and matter: but this is improbable, unless we understand, the first who taught that doctrine at Athens. Of the persecution which drove him from that city, there are different accounts. One is, that he was accused of being in communication with the Persian king, and condemned to death in his absence; another, that he was banished for his opinions, and starved himself to death at Lampsacus; a third, that he was found

guilty of impiety for his opinions respecting the Sun, and condemned to death, but saved by the intercession of Pericles; while Plutarch affirms that Pericles was his only accuser. Montucla, without citing his authority, says it was for an essay on the cause of eclipses that he was condemned. However this may be, he departed from Athens, and lived at Lampsacus on the Hellespont till his death, a period of twenty-two years. He died B.C. 428, aged seventy-two.

No works of Anaxagoras have come down to us, nor any astronomical observations from which we might form an opinion of his knowledge. He regarded the heavens as his country, and expressed himself to that effect when reproached for his indifference to his terrestrial birth-place. He is said even to have abandoned his wealth and honours from his zeal for study. When in prison he wrote a treatise on the Quadrature of the Circle; and he also wrote, according to Vitruvius, on Perspective. He is said to have written a treatise entitled *Actinographia*, which Montucla conjectures to be the last-mentioned work.

Among the various opinions attributed to Anaxagoras are the following:—that all substances are composed each of their proper parts, which are small and capable of infinite divisibility (see Lucretius, i. 830, &c.)—that the stars are stones torn from the earth, and set on fire by the æther which pervades the whole upper part of the universe—that the sun is a burning plate or globe, bigger than the Peloponnesus—that the moon receives light from the sun, (Plato says this opinion is anterior to him,) and has seas, hills, and valleys of her own—that the milky way is the shadow of the earth thrown upon the heavens: others say, he thought it consisted of stars of too feeble light to be seen by day—that the rainbow is caused by the clouds being held before the sun as a mirror—that winds are caused by the sun's heat rarefying the air—that earthquakes are caused by the effort of confined air to ascend—that snow is not white, but black (this opinion of his is reported by Cicero)—that the earth is flat, and that its inclination is the cause of the seasons—that the soul has an aerial body—and that sound and echo are conveyed to us by the air. Montucla protests against many of these opinions being supposed to be those of Anaxagoras, but we cannot see with what reason. That they are given by very various and doubtful authorities is true; but there is nothing so absurd in the opinions themselves, compared with others which we know to have existed at the same time, to warrant us in rejecting any one of them on that ground.

He is said, in the seventy-eighth Olympiad, to have foretold the falling of a large stone at Ægos Potami. [See *ÆROLITES*, p. 151.] Sixty-two years afterwards, the prediction was said to have been fulfilled before the defeat of the Athenians on that spot by Lysander.

ANAXIMANDER, the kinsman, pupil, and successor in the Ionic school, of Thales, was born at Miletus in the third year of the forty-second Olympiad, B.C. 610, and died there (as is supposed) about B.C. 547, aged 63. Little is reported of him, except that he was the first who constructed maps (see Agathemerus, lib. I. cap. i.) and gnomons, one of the latter of which he erected at Sparta; and that he first discovered the obliquity of the ecliptic. The latter is improbable; though, if he were the first who constructed a gnomon, it is probable that he would also be the first who gave anything like a measure of the obliquity. He is said, on the authority of a passage in an ancient history of astronomy cited by Fabricius, to have maintained the motion of the earth; but as most others assert that he placed the earth in the centre of the universe, Montucla plausibly conjectures that the passage *κινεῖται γὰρ τὸ πᾶν κατὰ μέτρον*, moves round the centre of the earth, should be read *κινεῖται γὰρ, &c.*, is placed at, &c. Some say he thought the earth spherical; others that it had the figure of a drum. At Sparta he is said to have predicted an earthquake which threw down the greater part of the city.

The similarity of the names of Anaximander, Anaximenes, and Anaxagoras, who succeeded each other in the Ionic school, has caused many opinions to be attributed to one which are by others given to another. It is, however, we believe, said of Anaximander alone, that he believed the sun, moon, and stars to be enormous wheels, encompassing and revolving round the earth, each having a round orifice in its circumference out of which fire issued; and that the stoppage of this orifice is the cause of eclipses. The latter part of this opinion is also attributed to Anaximenes.

ANAXIMENES, the pupil and successor of Anaximan-

der. He was born at Miletus. The years of his birth and death are not known, but he is said to have been alive at the overthrow of Cræsus by Cyrus, B.C. 546. Two epistles of his to Pythagoras are preserved by Diogenes Laertius, the genuineness of which may be questioned, since one of them gives an account of the death of Thales (his countryman and predecessor) very different from that given by Diogenes himself.

The opinions attributed to him are very much like those quoted in ANAXIMANDER and ANAXAGORAS. He held, in addition, that air was the first principle of all things—that the contraction of bodies is what is called cold, and their rarefaction heat. This he illustrated by observing that when we blow forcibly, condensing the air with the lips, it is cold; when with the mouth wide open, so as to allow the air to pass freely, it is warm. This is almost the only thing like an appeal to experiment (except the very doubtful measurement of the obliquity—see ANAXIMANDER) which we can find attributed to any of the successors of Thales; and even in this the philosopher is wholly mistaken. The contraction of bodies, generally speaking, produces heat; and their rarefaction, cold. The case cited is not at all in point.

There is another equally inconclusive illustration of the causes of thunder and lightning. Anaximander concluded that thunder is the noise made by the striking of one cloud by another, and lightning the glare arising from the friction. Anaximenes reinforces this conclusion by the observation, that the sea shines when struck by an oar.

ANBURY and CLUB-ROOT, a sort of galls produced by insects on the roots of cabbages, turnips, hollyhocks, and other species of cultivated plants, and popularly, but incorrectly, supposed to arise from peculiarities of soil, or from growing the same crop successively on the same field, or to be owing to variations of seasons. Nothing can be more simple than the disproof of all these theoretical notions. If we take some of the cabbages or turnips, whose roots are infected with anbury, and keep them in garden pots covered over with close gauze, in a short time, if the plants be kept growing, the little weevils, evolved from the grubs in the interior of the roots, will make their appearance, ready to multiply their species, by depositing their eggs, as their parents had done, on the first turnip or cabbage they can find; then is the critical time to destroy them, and prevent their increase. The weevil thus arising continues to be no less, but often more, destructive than the grub had proved to be in feeding on the roots; for it thrusts its beak (*rostrum*) into the seed-leaf of the turnip, and greatly injures the crop. Neither of these insects would ever breed in dung. When the turnip is advanced to the rough leaf, these insects either die, as most insects do, when they have laid their eggs, or betake themselves to some other plant, such as clover, which is suited to their taste.

It will be therefore evident, that no peculiar rotation of crops, nor peculiar manure for dressing the soil, can be of any avail in preventing anbury, or in stopping its progress when the insects have obtained a lodgement within the roots. The destruction of the adult insects before they have laid their eggs, is the only remedy, though in the case of so small a species, it is peculiarly difficult to put in practice.

ANCENIS, a town in France in the department of Loire Inférieure (the Lower Loire). It is a neat, pleasant town, situated on the north bank of the Loire, nearly twenty-two miles N.E. from Nantes, the capital of the department. It trades in corn, wood, fruit, wine, brandy, and vinegar. There is an ancient castle commanding the town, long inhabited by the dukes of Bethune. Ancenis has also a 'college' (high school), hospital, and barracks for cavalry. Population, 3145 (Malte-Brun); or 4000 (Balbi). The arrondissement of Ancenis contains about 41,000 inhabitants.

ANCHOR (from *ἄγκυρα*), a heavy iron instrument for fixing a vessel in a harbour or road, thence called an *anchorage*. It consists of a strong bar called the shank, having, at one end, a beam called the stock, which lies flat when at the bottom, with a ring beyond it, to which the cable is attached; it terminates at the other end in two opposite arms at right angles to the stock, to which are attached strong triangular plates, called flukes.

The anchor, which, under some form or other, must have been as ancient as vessels of any magnitude, is accordingly mentioned by many Greek and Latin authors, by whom also the invention, like many others, which, from clumsy beginnings, have passed through many stages of improvement, is

ascribed to various persons. The first anchors were, most probably, what they are now among uncivilized nations, namely, large stones, or crooked pieces of wood loaded with heavy weights. The Chinese, who may be supposed to adhere to ancient forms, are said to use chiefly crooked pieces of heavy wood.

Among the Greeks, the anchor was made latterly of iron. The first anchors had but one fluke; afterwards the other was added: but the anchor was yet without a stock, as appears from ancient monuments, and must have been very incomplete till the stock was added, which may, therefore, be considered as the last step towards the present form. Each ship then had several anchors; the chief one was called *iepa*, or sacred, and reserved for the last extremity. The custom and its proverbial application have come down to us in the expression 'sheet anchor'; but the veneration paid to its name has much declined since the custom of paying *5l.* to the master on letting it go was discontinued in the navy.

The number of anchors carried at both the bows and stern of a ship have been finally reduced to four principal, and these all at the bows. The anchors supplied to men-of-war are the best and small bowers*, the sheet, and the spare: these are of the largest size; to which are added, the stream and the kedg, which are used for particular or for temporary purposes, and are usually carried 'in board.' Since there is but small difference in the form of anchors of different weights, the stream of a large vessel serves for the bower of a smaller. The several parts of an anchor are shown in *fig. 1.*

The principles of the construction may be considered under two heads,—the purposes the machine is to fulfil, and the nature of the strains to which it is exposed. We will take at once the modern form to exemplify these considerations.

When the anchor is let go from the vessel's side, whether from a horizontal position of the shank (when it is held by the stoppers) or from a vertical position (when held entirely by the cat-stopper), as in *fig. 1*, the heaviest end, or crown, will tend to descend fastest, and the anchor, on having reached the bottom, will, most commonly, fall,—not in the position for holding, but upon the crown and on the end of the stock, because the stock moves with less resistance through the water in the direction of its length than of its breadth. From this position, therefore, the anchor is to be turned over or canted before it can hold. Now, it is evident that, if the stock were very short, the pull of the cable would tend rather to drag the end of the stock along the bottom

Fig. 1.

than to lift up one of the flukes, as must be done in canting the anchor; whereas, if the stock were longer, the cable would act with increased leverage, whatever might be the length of the shank in either case; hence the longer the stock, within the practical limits of stowage, the more cer-

* Called formerly bowyers, from being carried at the bows. (Harris's *Lexicon Technicum*.)

† Seamen by custom drop the *k* in 'peak and fluke, which they pronounce *vea* and *flua*.

tainly will the anchor turn properly, and, when hooked in the ground, the more powerfully will it resist any effort to overset it. Also, it is evident that the anchor will turn the more easily as the arm is shorter. In repairing old anchors, it is common to shorten the shank; in doing this, it is the custom also to shorten the stock in the same proportion. This, which is equivalent, in fact, to lengthening the arms, might, if carried to any extent, prevent the possibility of the anchor turning over, and therefore it appears that when the shank is shortened, the stock should remain unaltered. The amount of force required thus to overturn any given anchor might be found by calculation, or by actual trial; and it is remarked that the result of the former may be diminished by one-seventh when the anchor is under water.

The anchor being in the position of *fig. 2*, its weight, supposed to be collected at the centre of gravity, *G*, (not including the stock,) tends to force the fluke *F* into the ground; and this pressure on *F* will evidently be greater, as the vertical line *Gg* passes nearer to *F*; this pressure is $W \cdot \frac{Ag}{AF}$, (W = the weight, exclusive of the stock).

Fig. 2.

As soon as the cable pulls from *A*, it causes the fluke to catch or hook deeper, that is, it forces the fluke down; and the position of the fluke should be such as to form the angle most favourable for this purpose.

Suppose the arm *CF* imbedded, or the shank lying along the bottom, and the cable acting in the line *CA* with a tension *t*; then the pressure on the fluke taking place perpendicular to its surface, draw *FI* perpendicular to the fluke, and draw *FP*, tangent to the fluke, meeting *AC* produced in *P*; then if *PI* represent the tension *t* of the cable, *IF* will be the perpendicular reaction of the fluke, and *PF* the force which tends to drive it into the ground: draw *FH* perpendicular to *CA*, then *HF* is that part of *PF* which is perpendicular to the horizon, or is the effort of *t* to sink the fluke: let $\angle IPF = a$, then $FP = t \cos a$, and $FH = FP \sin a = t \cos a \sin a$, which is a maximum when $a = 45^\circ$; or the fluke should be placed at 45° to the shank. Now, it is remarked by seamen, that when an anchor is once started, it is difficult and often impossible to get it to hold again, and as this case is the most urgent of all, it is apparently the one to which the position of the fluke should be calculated.

Fig. 3.

It would appear, since the weight of a large anchor bears a much higher ratio to any given tension of cable than the weight of a smaller one, that the solution of the problem ought to involve the weight of the anchor, which would give a different angle for anchors of different weights; but it appears from numerous experiments which Lieut. Rodger has made on the qualities, as well as on the strength, of anchors, and which it is to be hoped will be made public, that an anchor, when dragged, always tends to rise out of the ground, thus following the direction in which the loosened soil affords a free passage;—since, therefore, it will not sink till it rests, and since its weight becomes less effective in pressing it farther the deeper it sinks, while the tension of the cable remains the same, it is thus constantly tending to the most favourable angle (when $= 45^\circ$) till the arm is entirely buried.

It appears from *fig. 2*, that in shortening the shank, the fluke, making already in most anchors the angle with the shank, or *FPI* in *fig. 3*, too great, will become still more nearly perpendicular to the horizon. In many such cases the pull of the cable will produce scarcely any tendency whatever to sink the fluke; besides which it is to be observed that by lessening the horizontal distance *AF*, while *Fg* remains the same, the pressure on the fluke is diminished, and thus on both accounts the qualities of the anchor impaired.

We now come to considerations relative to the strength of the anchor. It is obvious we have not the means of determining the amount of any of the forces concerned, but long experience has marked pretty nearly the limits beyond

which the dimensions of anchors need not be carried. With these we can determine satisfactorily the preference which should be given to one form over another.

The first strain that comes on the anchor when the cable is strained falls on the ring, which had been often broken or straitened, till its dimensions were of late years increased. This pull is conveyed along the shank to the lower arm, which it tends to break off at the greatest distance from the fluke, and therefore the thickness of the arm should increase towards the throat.

The crown, which formerly was a circular arc, of late years formed an angle, till changed by Mr. Pering.

The force to break the arm C F, *Fig. 3*, is the reaction perpendicular to the fluke, or F I, against the tension of the cable. And the moment of this force to break the arm C F at C, is as the perpendicular from C on F I. If the arm F C be straightened into F P meeting A C in P, then the moment of the same force is as P F, which is considerably greater than before. It would be curious, therefore, to know what reason led to change from the curved to the angular form.

In lifting or weighing the anchor, the cable acting perpendicularly to the end of the shank tends to break it, and hence the thickness of the shank should increase with its distance from the ring; also the breadth of the shank should be downwards, and the like holds good of the arms, the chief dimension of which should be in the plane of the cable and shank, thus opposing the greatest strength to the greatest strain. Some foreign anchors reverse this. The cable being thus 'up and down,' the smallest motion of the sea is carried to the anchor, and it is supposed that the chain-cable has thus, from its want of elasticity, frequently broken the anchor. An increased length of shank obviously renders this jerk less sudden and less severe; but increasing the length would require an increase of size or strength of the shank, whose length had already been found too great for the strength necessary in the employment of chain-cables; in order, therefore, to obtain this increase of length without either increase of weight or loss of strength, Lieutenant Rodger constructed his patent hollow-shanked anchor. The principle on which a hollow rod or bar is stronger than a solid one of equal sectional area is well known, but we cannot, within our limits, convey any precise notion of the manner in which the difficulties which attended the application of this principle to the shank of the anchor, were surmounted. An account, with drawings, is given in the *Repertory of Patent Inventions of July, 1830*, in which are given also the results of experiments tried at Hawks and Co.'s manufactory, Newcastle; from these it appears that his anchor broke short-shanked anchors of much greater weight without indicating any distress; and similar superiority has been exhibited on some other occasions.

Since the fluke from its breadth opposes greater resistance to being disturbed in weighing than the arm does, the axis of rotation will be towards the fluke, and accordingly the ground displaced by the angular motion of weighing being less than that displaced by fair pull,—and moreover the fulcrum or axis being near the throat in direct pull,—it seems that the force to lift an anchor out of the ground will be considerably less than the force sufficient by fair pull to bring the anchor home. Besides these strains to which the anchor is exposed by its office, it is liable to accidents; for instance, an anchor let go on a rocky bottom has been found, on heaving it up, to have lost an arm, which was, probably, caused by its striking against a rock obliquely in its descent; and this opinion is corroborated by the case recorded by Mr. Pering, of an anchor broken by swinging from the wharf against the side of the lighter brought to receive it. Again, the shank has been found broken in the middle, though this does not seem to have been accounted for satisfactorily, whether attributed to the chain-cable or to a sudden jerk; and it may here be observed generally, that the anchor descends much more swiftly with a chain-cable than a hemp one, for the stiffness of the hemp opposes a retarding force, while the greater density of the chain adds a continually accelerating force.

The shank and arms were formerly made of iron bars, welded together;—that this was done very imperfectly appears from the fractures in the old anchors. The arms and shank being made separately, were then joined together. A great improvement was made by Mr. Pering, who formed the shank of flat bars, of breadth equal to the depth of the shank, which could be perfectly united. But the greatest

of his improvements is considered to be the formation of the arms and part of the shank together, which is done by splitting, or dividing in two, these bars, and throwing the ends back opposite ways for the arms. Over the opening, or angle thus formed, is fixed a truss, and then to this are joined the flukes, and at the other end the remaining part of the shank. The bars are placed with their breadths downwards, thus receiving the strength of the cable in weighing, edgewise; Mr. Rodger places the breadths horizontally, forming the upper and lower halves of the (solid) shank separately, to be united afterwards, in order that the iron may bend rather than break, and with this object the iron is likewise drawn out to make it fibrous.

Various rules have been given for the dimensions of anchors, as, for instance, that the shank should be four-tenths of the main beam (*Aubin's Mar. Dict.*); but it is evident that neither beam nor tonnage relate directly to the magnitude of the anchor, because two similar ships may ride very differently at their anchors. The rough rule in the navy is 1 cwt. to a gun, thus an 80 gun-ship will have an anchor of 80 cwt.; and a merchantman of 200 tons having an anchor 10 cwt., 5 cwt. is added afterwards for every 100 tons; thus 300 tons would give 15 cwt., and so on.

The principal dimensions of the anchors in the navy may be stated shortly thus:—calling the shank 10, the arm is about 3, the breadth and depth of the palm about half this, the thickness or depth at *b*, or the small, .42, at the throat .6, which are nearly the dimensions of the arms also, and the breadths about $\frac{1}{2}$ of these, the edges being rounded. These general dimensions are taken from Pering's *Treatise*, 1819, since which other alterations have been made, principally in giving the section a diamond or lozenge form.

The weight of an anchor of 10 feet in length is, according to the same authority, about 11.4 cwt., and since, if the forms of all anchors were alike, the weights would be as the cubes of the lengths, the weight of any anchor might be found by multiplying the cube of its length by .0114. Thus the weight of an anchor of 14 feet in length would be $14 \times .0114 = 31.3$ cwt.; the weight of this anchor is, by the table, 30 cwt., hence as far as 30 or 35 cwt., the rule is near enough, but for larger anchors it gives the result too small, because their thickness is made greater in proportion. The weight of the anchor includes that of the ring.

As to the cost of an anchor, the labour per cwt. is about 24s. for an anchor of 10 cwt. and under, and for the largest anchors about 3l.; the value of an anchor of 95 cwt., including the iron at about 9s. 9d. per cwt., is about 300l.

The stock consists of two beams of oak, bolted and hooped together; the length is that of the shank and half the diameter of the ring; it is square; the side at the middle is an inch to a foot of the shank, and tapers to half of this at the end. Such a stock is nearly one-fourth of the weight of the anchor. Lieutenant Rodger has proposed a solid stock of African oak, for the greater convenience of stocking or unstocking.

Of late years iron stocks, whose weight is from one-fourth to one-fifth of the anchor, have been much used. Whatever convenience may attend them in small vessels, it seems very clear that their smaller diameter and greater weight under water will cause them to sink deeper in a soft bottom in the event of the anchor not turning over at once, and thus render this more difficult to do, especially as their length is limited to that of the shank. Small vessels require heavier anchors in proportion than larger vessels; the sea, sudden gusts of wind, and the pull of the cable affect the larger vessels less, and they thus preserve a steadier strain.

In forging an anchor, care is taken not to render the iron brittle. The effect of the hammer is to harden the surface by contracting it more than the interior. This is remedied by heating the whole to a dark red-heat, which, by expansion, restores the iron to a uniform state, and it is then suffered to cool gradually. This process is called annealing. A large mass of iron requires a very heavy blow to work it equally, or the outside only will be affected by the hammer; the steam-engine is applied for this purpose in Woolwich dock-yard.

Various forms of anchors have been proposed to answer particular ends; these our limits prevent us from entering upon. We have confined ourselves rather to the principles of the machine, which seem to have been very little considered, and have omitted several points. (See the *Encyc. Metrop.*, Pering's *Treatise on the Anchor*, &c.)

An anchor is said to be 'foul' when the cable is any way

entangled with it; to 'come home,' when the ship drags it; to be 'a-wash,' when the stock is hove up to the surface of the water; to be 'a-cock-bill,' when hanging vertically, as in fig. 1.

ANCHORET, sometimes written, and more correctly, *Anachoret*, a Greek word, signifying a person who has retired from the world. Under Christianity they sprung up about the middle of the third century in Egypt and Syria, where many believers came to hide themselves in caves and solitary wilds, from the fury of the persecution which arose under the Emperor Decius. Paul, commonly called the hermit, has the credit of having been the first regular anchorer. A distinction, however, came afterwards to be drawn between anchorers and hermits; the former name being given only to those who rigidly confined themselves to their caves or cells, and the latter to those who, although they had broken off all commerce with the world, still wandered about at large in the wilds to which they had retired. Both descriptions of recluse were entirely distinguished from the *Cenobites*, or those living in communities. Many of the anchorers were laymen; and there were also female as well as male anchorers. From nearly the commencement of the seventh century, the church assumed a jurisdiction over anchorers; and persons were not allowed to enter upon the mode of life in question except by permission of their ecclesiastical superiors, and after an appointed ceremony had been performed, at which the bishop presided. Churches and religious houses in the middle ages would sometimes keep an anchorer shut up in a cell, which was usually attached to the choir of the church. Such an attraction brought great crowds of the devout and the curious to the holy place, which benefited much by their offerings. It was eventually found necessary, in our own as well as in other countries, to lay down certain regulations with a view of discouraging the adoption of this solitary life. The most singular species of anchorers recorded in the history of the church, is that which arose in Syria in the fifth century, and of which Simeon Stylites was the founder. This zealot and his followers, instead of resorting, according to the customary fashion, to caves, elevated themselves into the air, on lofty pillars of stone, on the tops of which they passed their lives. They have hence received the names of pillar saints, holy birds, and aerial martyrs.

ANCHOVY (*Engraulis*, Cuvier), a genus of abdominal malacopterygious fishes, separated by Baron Cuvier from the *clupeæ* or herrings of Linnæus, from which they are distinguished by the superior number of their branchiostegous rays, amounting to twelve or upwards, by the gape of the mouth extending behind the eyes, and by the straight and prolonged form of the superior maxillary bones, which form a small muzzle, projecting considerably beyond the mouth. The genus, as at present constituted, consists of six or seven species, all of diminutive size, and with the exception of the common anchovy (*E. encrasicolus*), and a nearly allied species distinguished from it by M. Cuvier, (*E. meletta*) all inhabitants of the tropical seas of India and America. Whether these latter agree with the European species in the savour and other qualities of the flesh, for which it is so highly esteemed among civilized nations, is a doubtful question; at all events we are not aware that the fishing of the native species has ever been attempted either in America or India.

The common anchovy is a small fish, not much longer than the middle finger, of a bluish brown colour on the back and silvery white on the belly. The anal fin is remarkably short, and the dorsal situated immediately above the ventral; these characters will serve readily to distinguish it from the sprat and other kindred species, with which it might otherwise be confounded, and which are, in fact, not unfrequently imposed upon the public for the real anchovy. It abounds in the Mediterranean along the shores of Spain, Italy, and Greece; in the Atlantic it is found along the coasts of Portugal and France, and occasionally has been taken off the shores of England and Holland. Considerable fisheries of anchovies are established along the coasts of Provence and Catalonia; but the most productive of all is off Gorgona, a small island west of Leghorn. The latter fishery is carried on only during the months of May, June, and July, at which period the anchovies quit the deep seas and approach the shores for the purpose of depositing their roe; it is then only that they are found in the Mediterranean, which they enter in enormous shoals, by the straits

of Gibraltar, at the commencement of the breeding season, and leave it, after fulfilling this duty, to retire again to the depths of the Atlantic. They are fished for only during the night, and are attracted round the boats by means of charcoal fires which are kept burning in the sterns. After being caught, the heads, gills, and entrails are separated from the bodies, which are salted and arranged in small barrels, varying from five to twenty pounds in weight: this is the only preparation which they undergo, previously to being sent to market; and if proper means be taken to exclude the air, they will in this state keep for a very considerable period. If, when the barrels are opened, the fish are found to be small and firm, round-backed, with a silvery white skin and red flesh, and a plump, compact form, they are probably the true anchovy: if, on the contrary, they taper very much towards the tail, are of a dark brown colour without, and have flabby pale-coloured flesh, they will probably turn out to be the sardine (*E. meletta*), another Mediterranean species frequently mixed with real anchovies, or even sold separately as the genuine fish.

No condiment is more generally known and esteemed than anchovy sauce. Among the Romans, who called it *garum*, and prepared it exactly in the same manner as we do at present, its reputation was, if possible, still greater than among modern nations, and it appears to have formed an indispensable article of seasoning in their most expensive and luxurious dishes. The mode of preparing anchovy sauce consists simply in bruising and boiling the fish over a slow fire with melted butter; the action of the heat dissolves the whole body to a jelly, and in this form, when brought to a proper consistence, it is potted or bottled for use. This is the most common form of using the anchovy, but it is also sometimes brought to the breakfast table whole, and is then eaten raw. The importation of anchovies into the port of London is very considerable. Up to the year 1829 the average quantity annually imported amounted to about 100,000lbs. In that year, however, the duty was lowered from a shilling to twopence a pound, in consequence of which the importation of 1830 amounted to 260,000lbs, but declined in the following year, 1831, to about 30,000 lbs.

ANCHOVY PEAR. [See LAURUS.]

ANCHYLO'SIS, a Greek word (*ἀγκύλωσις*), signifying a bending. If the Greek orthography were strictly followed, the word would be written *ankylosis*.

An essential part of the apparatus of locomotion in animals consists of the structure termed a joint. (See JOINT.) Joints are so constructed as to produce various kinds and degrees of motion, in the execution of which it is necessary that the different parts constituting the joint should be in close contact with each other. Organized living surfaces, in close contact with each other, have a tendency to grow together; but such a union would at once destroy the action of a joint, and a specific apparatus is provided for the express purpose of preventing this event. What are termed articular surfaces, that is, the surfaces of joints, are covered with a thin and delicate membrane which secretes a peculiar fluid of an unctuous or oily nature, termed *synovia*. This synovia, the oil of joints, is in general effectual in keeping separate and distinct the different parts of the joint, however closely and for however long a time they may be in contact with each other; nevertheless, it does occasionally happen that a firm and complete union takes place between the different articular surfaces: when this occurs, it constitutes what is technically termed *ankylosis*, or, in common language, a stiff joint. An *ankylosis*, or a stiff joint, consists then of the immoveable union of two bones naturally connected together in such a manner as to form a moveable joint. All the moveable bones forming joints may become consolidated together, or *anchylosed*: and cases are on record of a general *ankylosis* of all the bones of the human body. Whatever keeps a joint motionless for a long time together may give rise to *ankylosis*. Hence it is apt to occur after the fracture of a bone in the neighbourhood of a joint; because it is necessary to the cure of the fracture that the limb should be fixed in one position, while the inflammation, occasioned by the violence that produces the fracture, often spreads to the joint, and it is one of the ordinary effects of inflammation to agglutinate and consolidate the parts inflamed. Hence inflammation, sprains, dislocation, shocks occasioned by leaping or falling on the feet from great heights, ulcers, are the common causes of *ankylosis*. But *ankylosis* cannot always be

considered in the light of a disease; at any rate, it is sometimes the happy termination of a formidable malady. The natural cure of many painful and dangerous diseases of the joints is the formation of an anchylosis. When an anchylosis is forming, and is clearly inevitable, and is, indeed, a thing to be desired, the position in which the limb is kept, or the position in which the bones are allowed to unite, is a matter of great importance to the future comfort of the individual. When, for example, from injury done to the hand, the joints of the fingers are undergoing the process of anchylosis, it is very important to keep the fingers bent, because, if they anchylose in that position, the hand will be more useful than it could be were the fingers permanently extended. On the contrary, when there is danger of anchylosis of the knee-joint, the limb should be kept as straight as possible, because, if the leg be extended, the limb will be more useful than if it were permanently bent. On the other hand, when anchylosis of the elbow-joint cannot be prevented, the limb should always be kept bent. Considerations of this sort are of great importance; they are never neglected by the intelligent surgeon; and they tend to lessen the inconvenience and suffering of an inevitable calamity. They ought in every such case to be presented to the view of the patient, who should be made to understand, as far as possible, the ground on which the plan that may be pursued is adopted, in order that he may co-operate with his medical attendant in lessening the evil that cannot be averted, and in securing whatever advantage it is possible to obtain.

ANCIENT, ANCIENTS; or ANTIENT, ANTIENTS. The term *ancient*, which we derive from the French word *ancien*, has the primary meaning of 'very old,' as when we say 'an ancient building,' 'an ancient family,' implying only that many generations have passed since they first came into existence. But it is also used in a more limited sense, with reference to a certain period in the existence of the human race; as when we speak of ancient, as distinguished from modern, history; of the ancient classics, ancient literature, and generally, of the *ancients*. The boundary line between ancient and modern in this latter sense is not very accurately drawn; but according to the vulgar acception of the terms, the period of the ancients seems to be closed by the final and complete overthrow of the western Roman empire. With reference to the nations over which that empire extended, the distinction is not altogether arbitrary, or without an intelligible reason. The overthrow of the Roman empire marks the commencement of a new order of things, when we begin to discover the rudiments of those powerful independent nations, of those various languages, and peculiar institutions, which so remarkably distinguish a large portion of what is called modern Europe, from Europe under Roman dominion. There is of course a short interval, which may be considered as doubtful ground, for the possession of which the terms ancient and modern will always be allowed to contend.

It is plain that the reason here given for the commonly received distinction is applicable only to the west and south of Europe; yet the same distinguishing terms are familiarly used, and in many cases the same date arbitrarily assumed with reference to the rest of the world. This practice is attended with many difficulties, and produces no little confusion. The eastern Roman empire, for instance, survived the western by many centuries; nor can any good reason be given why the subjects of Justinian and his predecessors should be classed among the ancients, and those of his successors among the moderns. If the question were asked, where should a Greek author in a late period of the eastern empire be placed, we could not call him either an ancient or modern Greek writer without giving cause for considerable misapprehension. In the case of the oriental nations, the same terms are still applied, and often perhaps with no very distinct notion of their import, even by those who employ them. We hear commonly of ancient and modern Persia, ancient and modern India. Now, in the case of the Persian empire, in seeking for a date, we might choose between the conquests of Alexander the Great, the irruption of the Parthians, the restoration, as it is called, of the old Persian dynasty, and its subjugation by the Mohammedans. Any one of these events, and especially the last, would furnish perhaps better ground for the distinction of ancient and modern Persia, than any thing which occurred at the time of the overthrow of the Roman empire.

It might be expected that the convenience of having at hand such terms as ancient and modern would often

lead to some abuse, and this is particularly observable in the vague reference so frequently made to 'the ancients.' There is no definition which excludes from their number any who lived from the time of Noah down to the last Roman emperor; and it is obvious, that there is not much which can be safely predicated of a class so large and comprehensive, yet we often hear of what 'the ancients' said, and did, and thought. Allusion is made to the military tactics or the philosophy of the ancients; comparisons are instituted between the literature of the ancients and moderns; and we are told of the sentiments on certain subjects entertained by the heathen ancients. The truth is that by 'the ancients,' we must understand, on many of these occasions, Greeks or Romans at certain periods of their national history; and even thus limited, there are few assertions which will hold good of 'the ancients' generally. For the most part, perhaps, the looseness of the expression is corrected and limited by the subject or the context; but it is also true, that real misapprehension has arisen from the practice of throwing together and confounding the most dissimilar things by the help of this comprehensive term.

This is not the place to enter on the consideration of ancient and modern history, but there is an evil in some measure connected with the use of these terms, which it may be worth while to notice. It is to be feared that the common division of the subject of history into two parts, ancient, and modern, too often conveys the notion of an actual separation which does not exist. The young student pictures to himself a great gulf between them. When busy with the ancient part of the subject, he imagines himself to be conversing with beings of a different nature from himself. He believes the narrative, but is affected by it much as he would be by a work of fiction. When he has crossed the gulf, and passed from the obscure regions of ancient history into the stronger realities of modern times, he converses freely with beings of the same flesh and blood with himself. It is not requisite to enumerate all the bad effects which must arise from this impression. It is evil enough that the student must necessarily overlook the important fact, that the subjects of what are called ancient and modern history are so far one and indivisible, that a liberal and comprehensive view of the ancient part is necessary for the profitable study of the modern.

ANCILLA or ANCILLARIA, are the names given by Lamarck to a genus of spiral, univalve, marine shells, allied to the olives. Like them they are covered with a hard shining coat, destitute of any periostraca, and are imbedded in the large foot of the animal, so that the middle of the back of the shell can be alone discovered. They chiefly differ from the *olives* in the suture of the whorl, being callous and not furnished with a groove, formed by a thread-like filament placed at the end of the mantle, which is wanting in this genus: they are also furnished with a small ovate operculum. The species are numerous, and are chiefly confined to tropical climates: some have a small tooth, like the unicorn shell (*Monoceros*), placed at the end of a groove crossing the front of the shell. The best known species is the *ivory shell*, which with a few others differ from the rest of the genus in having the front of its axis deeply pierced.

ANCILLON (CHARLES), the son of David Ancillon, was born at Metz, on the 28th of July, 1659. After having studied at Marbourg, Geneva, and Paris, he was admitted to the bar in Paris, and then commenced the practice of his profession in his native place. He was obliged, however, along with his father, to leave Metz on the revocation of the Edict of Nantes. When the elder Ancillon some time after settled in Berlin, Charles followed him thither, and the elector of Brandenburg appointed him judge and director of the French inhabitants of that city. He was afterwards promoted to the offices of inspector of the tribunals of justice for the refugees in Prussia, superintendent of the French school, and royal historiographer; and was also employed by the elector on a diplomatic mission to the Swiss Cantons. He died at Berlin on the 5th of July, 1715. Ancillon, who was one of the most learned lawyers of his time, is the author of various works, both upon subjects connected with his profession and others, the principal of which are enumerated in the *Biographie Universelle*, our authority for the above facts. The production for which he is now chiefly remembered is his *Traité des Eunuques*, 12mo., 1707, which is said to contain a great deal of curious learning.

ANCILLON (DAVID), a very learned French Pro-

stant clergyman, the father of the subject of the preceding article. He was born on the 17th of March, 1617, at Metz, where his father was an eminent lawyer. Having attended for some years the Jesuits' College there, he went to Geneva, in 1633, to complete his studies in philosophy and theology; and in 1641, was licensed to preach by the synod of Charenton, and appointed minister at Meaux, the most important of the stations under their jurisdiction then vacant. Here he remained till 1653, having in the mean time married a lady of large fortune. The match is stated to have been arranged by his congregation, with the view of retaining him among them. In 1653, however, he accepted a call to his native town of Metz; and here he continued to officiate with great reputation till the revocation of the Edict of Nantes, in 1685, when he retired to Francfort. He was soon after chosen minister of the French church at Hanau; but this post, after a short time, he voluntarily resigned, having been induced, it is said, to take this step by the annoyances which he suffered from his brother clergymen, who were jealous of his superior eloquence and reputation. At first he went back to Francfort; but soon proceeded to Berlin, where he was received with great favour by the elector of Brandenburg. Here he continued to reside till his death, on the 3d of September, 1692. He is the author of several works, principally in defence of the reformed faith, the titles of which may be seen in the authorities referred to below. Perhaps, however, the most favourable impression of his varied learning is to be obtained from the work, entitled *Mélange Critique de Littérature Recueilli des Conversations de feu M. Ancillon*, published at Basle, in 1698, in two volumes, 12mo., by his son Charles. It is a collection of the colloquial remarks of M. Ancillon, and has been often classed with the *Scaligerana* and other publications with similar titles, although the editor in his preface gives his reasons for not designating it *Ancilloniana*. An extensive and valuable library which this learned clergyman had collected by a large expenditure during forty years, he was obliged to leave behind him when he fled from Metz on the revocation of the Edict of Nantes; and the books and manuscripts were all pillaged and dispersed. A life of Ancillon was published at Basle, in 1698, by his son Charles, in a duodecimo of 300 pages. (often to be found forming the third volume of the *Mélange Critique*), with the title of *Discours sur la Vie de feu M. Ancillon et ses Dernières Heures*; and he is also the subject of an article of considerable length in the second and subsequent editions of Bayle. The above particulars have been chiefly taken from the latter source. (See also the *Biograph. Universelle*.)

ANCLIFFE, or ANCLIFF, a hamlet near the town of Wigan in Lancashire, where was formerly a singular well, called by the inhabitants the 'burning-well.' The true cause of the phenomenon appears to have been the escape of carburetted hydrogen gas from the earth at the bottom of the well, which, passing rapidly through the water, gave it the appearance of boiling, and took fire if a lighted candle was applied to the surface. Leigh (*Nat. Hist. of Lancashire*, &c., Oxford, 1700) thus describes it:—'It is about two miles from Wigan, in a village called Ancliff, in the ground of William Molineux, Esq. of that place. The well is at the bottom of a tree, the water cold, and without any smell; when any person comes to see it, a man clears the well from all its water: that done, you will immediately hear a hissing noise in a corner of it, and by holding a lighted candle near to it, the sulphureous *halitus* (vapour) immediately takes fire, and afterwards spreads itself upon what water has issued in, and it is only then indeed it ought to be called the burning-well. It is observable, though this sulphureous *halitus* continually mixes with water, yet the water continues cold, nor will it tinge silver.' An account of it by Thomas Shirley, Esq., in the *Philosophical Trans.* No. xxvi. p. 482. corroborates the above statement in its main points. 'When the water was cleared away, the cone of the flame ascended a foot and a half from the surface of the earth: the basis of it was of the compass of a man's hat about the brim. I then caused a bucket full of water to be poured on the fire,' adds Mr. Shirley, 'by which it was presently quenched. I did not perceive the flame to be discoloured like that of sulphureous bodies, nor to have any manifest smell with it. The fumes when they broke out of the earth and pressed against my hand were not, to my best remembrance, at all hot.' The well, or its peculiar property, is now lost. *Beaut. of Eng. and Wales*.

ANCONA, a seaport town in the Papal states, on the coast of the Adriatic sea, 43° 38' N. lat. 13° 35' E. long. Ancona is the capital of a delegation or province, governed by a delegate who is a prelate of the Roman church. The court of appeal for the whole of the marches and of the duchy of Urbino sits at Ancona. This town is the most commercial place in the Papal states; it carries on a considerable trade by sea, and is a free port. Its harbour, which is good, is protected by two moles, the antient one raised by Trajan, and the new one with the light-house constructed by Pope Clement XII., after the designs of the architect Vanvitelli, who also began the handsome lazaretto for the quarantine of vessels coming from infected countries, which was completed by Pius VI. On the antient mole stands a fine triumphal arch dedicated to Trajan, his wife, and his sister; the order is Corinthian, and the material Parian marble, which still retains its whiteness. It is entire, though long since stripped of the metal ornaments, statues, and busts with which it was once decorated. The arch has only one gateway, and is ornamented with four columns on each front.

The town of Ancona is built on the declivity of a hill which forms a semicircular promontory. The streets are narrow and gloomy, except one fine street, which Pius VI. opened, leading to the mole. The citadel, built on a hill, commands the town and harbour, but is itself commanded by the neighbouring heights. The cathedral is a very old structure, built outside the town, on the site of the former temple of Venus, and near the point of the cape, from which there is a fine view of the coast of Romagna and of the Adriatic sea. The other remarkable buildings are the town-hall, the merchants'-hall, the arsenal, and the churches of the Dominicans and the Augustins.

Ancona is said by Strabo (p. 241, Casaub.) and Pliny to have been built by some Syracusans who fled from the tyranny of Dionysius. Juvenal calls it a Doric colony; it is probably older than the date assigned to it by Strabo. The name of *Ancon* (ἀγκών) means an elbow, such being the shape of the neck of land on which it is built. The Romans made it one of their principal naval stations on the Adriatic. In the middle ages, it governed itself as a republic under the protection of the popes, until 1532, when Clement VII., partly by artifice and partly by force, made himself absolute master of the town. The French occupied it in 1797, and it was afterwards retaken by the Austrians in 1799, after a long siege. A French expedition by sea took possession of the citadel again in 1832.

The situation of Ancona is pleasant and healthy, the country around is very fertile, and the women are reckoned among the handsomest in Italy. The population, according to the latest accounts, is about 30,000, of whom 5000 are Jews. Ancona exports wax, silk, wool, and corn. It is the best, indeed the only good harbour on the Italian coast of the Adriatic between Venice and Manfredonia, and is the common point of departure for the Ionian islands and Greece. Packets are established between Ancona and Corfu.

ANCRE, (MARÉCHAL and MARQUIS D'). To this high military rank and title was raised a poor and obscure Florentine gentleman of the name of Concini dei Concini, son of a notary. He came to Paris in the suite of Maria de' Medici, whom Henri IV. of France espoused after he had repudiated Marguerite de Valois. Concini soon after his arrival married Eleonora Galigai, one of the queen's women of the chamber. Both were ambitious, persevering, and endowed with those abilities which, at that time, ensured success at court. On Maria de' Medici becoming regent after the assassination of Henri IV., the elevation of Concini was extremely rapid. He was first made equerry to the queen, then master of the horse, and soon after his purchasing the marquisate of Ancre (under which name he is known in history) he was made first gentleman of the king's chamber. The dignity of Maréchal of France was also conferred on him by the Queen Regent. Such sudden elevations, and rapid accumulation of immense wealth, not only gave rise to suspicions very unfavourable to his character, but excited the jealousy of the court. His insolence to the young king and his overbearing manner to the nobles were the cause of that hatred which brought him to a dreadful end. For some time attempts were made, but in vain, to hurl the Italian adventurer from his envied elevation; the princes themselves joined against him without success. However, a young man of the name of Laynes, (known afterwards as Duc de Laynes,) who was in great

favour with the young king, persuaded him to deliver the queen-mother from the power of her favourite, and urged his insolent bearing to the nobility, and his pernicious influence, with so much success, that at last Louis XIII. ordered the Maréchal to be arrested, and even to be put to death if he resisted. Vitry, a captain of the king's guard, was entrusted with this commission, which he executed to its fullest extent. Ancre was shot dead as he was entering the palace of the Louvre. On hearing the shot, the king looked out at the window, and expressed his satisfaction, which he testified by raising Vitry to the rank of Maréchal of France. The body of the murdered man was first secretly buried at St. Germain l'Auxerrois, but was soon after torn from the tomb by the infuriated mob, who dragged it through the streets on hurdles and then threw it into the highway. Concini's son, sixteen years of age, was obliged to fly to Florence, after having been exposed to all sorts of insults, and deprived of his father's titles and riches. Eleonora soon shared the misfortunes of her husband. She was accused and convicted of sorcery, judaism, and corruption; and was executed at the Place de Grève, on the 8th of July, 1617. During her trial, and at the moment of her execution, she displayed the greatest firmness of mind, saying, the only sorcery she had used towards the queen 'was the power of a strong mind over a weak one.' It is said she was the first instrument of the fortune of Richelieu.

ANCUS MARCIUS, the fourth king of antient Rome, belongs to a period when it is difficult to separate history from fable. The reigns of the kings of Rome seem to mark the chief stages of progress in the political constitutions of the state, rather than the succession of individual monarchs. The names of Romulus, Numa, and Tullus Hostilius are respectively connected with the origin of the three patrician tribes, the Ramnes, the Tities, and the Luceres, and with their settlement upon the several hills called the Palatine, the Quirinal, and the Cælian. Thus, under the three first kings, the patrician part of the Roman constitution had received its full development. To Ancus Martius, tradition assigned the honour of laying the first foundation of the *plebes*, or commonalty, that important element in the state, to which Rome, under the commonwealth, owed nearly all her greatness. His predecessor, attentive solely to war, had neglected the religious institutions established by Numa, and for his impiety had been destroyed by a thunderbolt with all his family. Ancus Marcius, whose mother, according to the tradition, was the daughter of Numa, restored the neglected rites, and endeavoured in all respects to imitate the pacific policy of his grandfather. But the neighbouring states, mistaking his love of peace for timidity or sloth, provoked him to hostilities by repeated aggressions on the Roman territory. In the successive wars with the Latins, the Veientes, and other states, which ensued, he was invariably successful. From the Latins he took the towns Politorium, Tellenæ, Ficana, Medullia, and transferred their inhabitants to his capital, giving them as a place of abode, not indeed any ground within the walls, but a part of the Aventine and the valley near the temple of Venus Murcia which separated that hill from the Palatine. Ancus was thus the founder of the *plebes*, and his assignment of part of the public domain to that body procured him in after times from one party the title of the 'Good Ancus,' (Ennius in Festus, v. *Sos*, quoted too by Lucretius, iii. 1038); others condemned his unworthy love of popularity (Virg. *Æn.* vi. 816). The Latin towns just mentioned are supposed to have been situated between Rome and the coast; and indeed the conquests of the king extended to the mouth of the Tiber, where he established a colony under the name of *Ostia*, thus securing to Rome the navigation of the river. In his war against Veii he was equally successful; and to protect his people on that side he fortified the *Janiculum*, and connected it with the city by means of the Sacred Bridge called the *Fons Sublucius*, in the construction of which no brass or iron was used. This bridge, repaired from time to time under the direction of the college of priests called *Pontifices*, (bridge-makers,) who religiously adhered to the principle of excluding all metal, lasted until the year 23 B.C., when it was carried away by an extraordinary inundation of the Tiber, and its place supplied the following year by a stone bridge erected by the censor Æmilius Lepidus. A still more durable monument connected with the name of Ancus is the prison formed out of a quarry in that side of the Capitoline hill which overlooks the Forum. It would be idle to copy from Dionysius the detailed account of the

transactions which are said to have filled the reign of twenty-three or twenty-four years assigned by the chronologists to this monarch. It has been already stated that Ancus Marcius was said to be the grandson of Numa. In this tradition Niebuhr sees a trace of the regulation by which the kings of Rome were chosen alternately from the two leading tribes. The plebeian family of the Marcii vainly endeavoured to refer their origin to this king. (Livy i. 32-35; Dionysius iii. 36-45, with Niebuhr's *Roman History*, translated by Hare and Thirlwall, vol. i. p. 346-350.)

ANCYLUS is the name of the shell which is usually called the fresh-water limpet. They are small, pellucid, conical shells, with slightly recurved tips. The cavity is simple, and marked with a horse-shoe-shaped muscular scar near the margin, which is interrupted on the middle of the left side over the respiratory holes, as in the genus *Siphonaria*. This animal, like the pond-snail (*Limnea*), has two compressed triangular tentacles, with the eyes sessile on the outer base; and a respiratory cavity placed on the middle of the back, with an aperture closed by a valve opening in the middle of the left side.

This genus is very nearly allied to the pond-snail, *Limnea*, from which it chiefly differs in the simple conical form of its body and shell, and some species, as *Ancylus*, are allied to it by having the apex bent on one side, as if making an approach to the spiral form. It has been placed in several orders, but there is little doubt that its true situation is with the lung-breathing mollusca. Treverianus has mistaken the lid of the respiratory opening for a gill: and Rang places it with the *semipillediens*. They are found in Europe, America, and the West Indies, attached to stones and plants, and they will live a considerable time out of the water. They are easily known from the *Siphonariae*, which are the only shells they can be confounded with, by their being sinistral, very thin, and covered with a hairy periostraca.

ANCY'RA, now Angora, or Engour, was one of the most important cities of Asia Minor. Tradition ascribed its origin to Midas, and its inhabitants exhibited in a temple of Jupiter a sacred anchor, which was said to have been discovered at the time of its foundation. This was, probably, a Greek invention, to account for the name of the city, but be this as it may, an anchor appears on the coins struck in the reigns of Antoninus, Severus, and Caracalla. When the hordes of Galli or Galatæ established themselves in the heart of Asia Minor, Ancyra became the capital of a tribe which had originally come from the neighbourhood of Toulouse, called Tectosages. In A.C. 189, the whole of Galatia was subdued by the arms of Manlius, and from this time it was for the most part virtually dependent upon Rome. Towards the close of the Republic, Dejotarus, who, by right, was the Tetrarch of the Tectosages alone, had extended his authority over the other Galatian tribes, and even assumed the title of king: but under Augustus (B.C. 25) it was found convenient to reduce the whole country to the form of a province, of which Ancyra was still the capital. Though deprived of its nominal independence, the city flourished under the favour of Augustus, and the inhabitants in their gratitude appear to have offered religious honours to the monarch. The city was permitted to assume the name *Sebaste*, (the Greek term corresponding to the Latin *Augusta*), and at the death of the emperor, when an inscription on brass was erected at Rome to commemorate his achievements, the citizens of Ancyra procured a copy and had it inscribed on 'marble in Greek and Latin, and placed in one of their public buildings, which was probably a temple dedicated to Augustus, under the character of Lunus. This inscription, called the *Monumentum Ancyranum*, was discovered in 1554, by Wrantz, bishop of Agria and ambassador from Ferdinand II., at the Ottoman Porte. A more correct copy was taken by Tournefort in 1701, and by him communicated to Chishull, who ably supplied many of the lost words by conjecture, and published it in his *Asiatic Antiquities*. It has been repeatedly printed since, particularly as an appendix to the writings of Tacitus. (See Oberlin's edition, tom. ii., p. 586.) The greater part of the Latin inscription was still standing in the building as it had been originally put up, but in many parts it had been mutilated in the attempts to remove the copper cramps with which the different pieces of marble had been connected together. Suetonius, in his *Life of Augustus*, c. 101, speaks of the original inscription at Rome, from which the *Monumentum Ancyranum* was copied. Augustus, says he,

besides his will left four volumes, one of them containing a summary of all his achievements, which he wished to be cut in tables of brass and erected in front of his mausoleum. This inscription, by its historical importance, fully deserves the title of the monument of Ancyra, but there are many others which are worthy of mention, particularly that which Montfaucon has given in his *Palæographia*, p. 154, containing an enumeration of public festivals at the expense of certain individuals there named. Among these public benefactors, one cannot but remark Albiorix, the son of Ateporix, two names which bear a strong resemblance to those which occur in Cæsar's *History of his Gallic Wars*, as Dumnorix, &c. Other inscriptions may be seen in Tournefort's *Voyage du Levant*, tom. ii., but this traveller was compelled to leave many unnoticed. A skillful antiquary, he observes, would still find inscriptions enough to occupy a year in copying. The high importance of Ancyra under the empire is proved by the numerous coins it issued, and by the immense number of its public buildings, the scattered remains of which are seen in all quarters of the present city. Above all was it celebrated as one of the chief seats of religion, so that Libanius calls it the sacred city. Coins and inscriptions refer to the worship of Jupiter, Ceres, Bacchus, Pallas, Apollo, Cybele, Lunus, Salus, Æsculapius, Serapis, the Dioscuri. It was also the seat of one of the earliest Christian churches, founded, probably, by the apostle St. Paul: accordingly, in the years 314 and 358, Christian councils were held here. Pagan worship, however, had not yet ceased, and when Julian visited Ancyra in 362, he was received without the walls by religious processions from all the temples of the city. As the power of Rome declined, the frontiers were exposed to the ravages of various enemies. In 625, Ancyra was taken by a general of the Persian Chosroes. In the following century it twice fell into the power of the Arabs. In 1085, it was taken by the Turks, but in 1102 recovered for a time by the Franks. After being for a considerable period the capital of the Turkish empire, it again changed masters in consequence of the great battle between Tamerlane and Bajazet, which was fought in the adjoining plain, July 28, 1402. In 1415, it was recovered for the Turks by Mohammed I., and since that period has always belonged to the Ottoman empire. The population, according to the Abbé Belley, consisted of 40,000 Turks, 4000 or 5000 Armenians, having seven churches, and 600 Greeks, having two churches. The present population is not known, though it is considerable. Its chief commerce consists in articles manufactured from the bright, silk-like wool of the Angora goat. At the beginning of the last century, there were resident merchants there from England, France, and Holland. The town is situated near the sources of the most eastern tributary of the Sakaria, or Sangarius, and at a distance, according to our maps, of about twenty miles from the Halys, which, in that quarter, reaches its most western limit. In Leake's *Map*, twelve antient and modern roads are seen to meet in Angora, which is the best evidence of the importance of the city. It has been visited by Tournefort, Lucas, Pococke, Brown, Bruce, Kinneir. It lies in $32^{\circ} 46'$ E. long., $39^{\circ} 52'$ N. lat. (See Tournefort, *Voyage du Levant*, tom. ii., p. 244; *Mémoires de l'Académie des Inscriptions*, tom. xxxix., p. 391; Rasche, *Lexicon Rei Nummarie*, article 'Ancyra.') There was another Ancyra in Phrygia Epictetus, the precise position of which is unknown. The coins of both towns have the name in the form ANKYPA, not ATKYPA.

ANDALUCI'A or ANDALUSI'A, the most southern of the provinces of Spain, comprises the four Moorish kingdoms of Seville, Cordoba, Jaen, and Granada. It is situated between $36^{\circ} 4'$ and $38^{\circ} 25'$ N. lat., and 2° and $7^{\circ} 20'$ W. long.; is bounded on the north by La Mancha and Estremadura, on the east by Murcia, on the south-east by the Mediterranean, and by Portugal on the west; it extends, in its greatest length, 320 miles from east to west, and 144 from north to south. It was included in the Roman province of Bætica, so called from the river Bætis, now Guadalquivir. The present name, according to the most general opinion, it received from the Vandals, who established themselves in it about the beginning of the fifth century of our æra.

Two chains of mountains traverse this province; the most southern, and that which also has the highest summits, is called the Pæno-Bætic range by some geographers. It extends from Tarifa to Cape Gata, a distance of about 240 miles in length, without reckoning its sinuosities or wind-

ings; its breadth, from the Sierra de Bedmar to Cape Sacratif, is from 75 to 80 miles. The direction of this chain is first from south to north, and then from east to west: in its course it takes different names. The Sierra de Gazales, which is the most southern branch of the mountains of Europe, extends from $36^{\circ} 4'$ to $36^{\circ} 30'$ N. lat. The Sierras of Ronda, Abdalaziz, and Prieta then follow in a direction from south-west to north-east from $5^{\circ} 12'$ to $3^{\circ} 57'$ west long.; then follow the Sierras of Loja, Alhama, Tajada, and Lujar, and approach the shore of the Mediterranean in a direction from north-west to south-east, from $3^{\circ} 57'$ to $2^{\circ} 57'$. From the Picacho de Veleta it takes the name of Sierra Nevada, and then runs from west to east as far as $2^{\circ} 27'$, after which, taking a direction south-east and afterwards south, it becomes the Sierra de Filabres. This Sierra joins the Sierra de Aljamilia, and divides itself into two branches, one of which abuts on the sea at Cape Gata; the other branch proceeds eastwards to the Torre de Roldan. The inferior range of mountains parallel to the Sierra Nevada, for the distance of about 45 miles from Motril to Almeria, is called Alpujarras, an Arabic name, meaning grass and pasture mountains. This chain includes the Sierra de Gador and Contraviesa, and its western extremity joins the heights of Lujar and Jolucar. The strata or rocks which form the Sierra Nevada are inclined in a direction almost parallel to that of the central chain. The slope of the Alpujarras is abrupt on the north, but on the south it extends itself gradually, so that the hills slope down to the sea-shore.

The Sierra Nevada is mainly composed of mica-slate which passes into gneiss and clay-slate: on the south slope the clay-slate rests on the mica-slate, and is covered by a black transition limestone rock, rich in sulphuret of lead. Near Granada there is a quarry of serpentine on the banks of the Genil: it is green, mixed with a great quantity of blue, and susceptible of a good polish. Fine marbles, also, and alabasters of a brilliant white colour, but of a very soft quality, are found near Granada. This chain has several points covered with perpetual snow, the highest of which Mulhacen, is 11,660 feet above the sea. The next in height is the Picacho de Veleta, 11,385 feet. This point offers one of the most imposing views in Europe. In the centre of a magnificent panorama, the observer beholds himself surrounded by snow and tremendous precipices; farther on to the north he perceives the inferior summits of the chain, terminating in verdant plains bounded by the summits of the Sierra Morena, a distance of about eighty miles, and on the south he beholds at his feet the waves of the Mediterranean beating against the rocks of the shores, and in a clear day he may perceive the coast of Africa, distant about 125 miles. The lake of Caldera, which is the source of the Guadalfeo, is on the Mulhacen and 10,112 feet above the sea. The Sierra de Gador is 6575 feet high, and covered with snow three parts of the year. The Cresta de Gallo, or Cock's Comb, in the Sierra de Ronda, to the S.E. of the town of that name, is the first point discovered by ships approaching Cadiz. The hermitage of Nuestra Señora de las Nieves, (our Lady of the Snow,) on the same mountain, is elevated 6011 feet. (See *Orographie de l'Europe*.)

This range being so contiguous to the sea, the rivers on the south side may more properly be called torrents than rivers: the principal of these, the Guadiaro, the Guadalorce, the Adra, the Almeria, and the Guadalfeo, fall into the Mediterranean. The Genil, the Darro, celebrated for the particles of gold found in the sand which it carries, the Guadiana Menor, and a few others of less note, swell with their waters the current of the Guadalquivir.

A branch of the Pæno-Bætic chain which serves as a boundary to the plains of Granada on the north, connects it with the Marianic range by its junction with the Sierra de Cazorla. The length of this chain from Cape St. Vincent to the Sierra Segura, in Murcia, including the mountains of the Algarves, is about 360 miles, and its greatest breadth between Cordoba and the river Guadalmeiz nearly sixty. From its eastern extremity to the source of the river Tinto, near the boundary of Spain and Portugal, between $2^{\circ} 32'$ and $6^{\circ} 12'$ W. long., it runs from E.N.E. to W.S.W., that is, almost parallel to the Pæno-Bætic, and takes the names of Sierra de los Pedroches, Cordoba, Constantina, Guadalcanal, and Monasterio. At the last point it is divided into two branches, one of which takes the name of Sierra Albaleira, and runs in a western direction to the banks of the Guadiana; the second proceeds south-westwards under the name of Sierra

de Aroche, and is separated by the Guadiana from the Sierras of Caldeirão and Monchique in Portugal: the Caldeirão runs W.N.W., and the latter S.W., and partly form the southern limits of the province of Alemtejo in Portugal. This range does not contain any remarkable summits, nor any of sufficient elevation to retain the snow for nine months in the year. The heath, kermes-oak, and other plants of shining and dark green leaves, with which it is covered, give it a dark appearance, from which the name of Sierra Morena, or Dark Mountain, is given to part of the range. Its formation is principally schistose; the Sierra de Caldeirão presents volcanic remains, and basalt is found near Almagro on the high road from Madrid to Cadiz. Though the Marianic range is the great boundary between the waters of the Guadiana and Guadalquivir, yet many rivers which have their sources on the north side of the chain intersect it, and fall into the Guadalquivir on its right bank; except the Tinto and a few more, which empty themselves into the ocean between Moguer and Huelva. The Sierra Morena contains the richest deposit of minerals in Spain: it produces mercury, lead, copper, silver, and gold: it is also exceedingly abundant in pasture, and well adapted to cultivation. The high road from Madrid to Andalusia cuts this chain in its narrowest and most elevated part, called Despeña Perros, or the Precipice of the Dogs. Another communication is open in this chain, which connects Andalusia with Estremadura by the Puerto of Monasterio. These are the only roads in the Sierra Morena: there are other communications through it, which, if not impracticable, are at least very insecure.

The Guadalquivir is the largest river in Andalusia. Bory de St. Vincent says that its real source is the Guadarmena, a river which, springing in the north-eastern extremity of La Mancha, flows in a direction south-west, cutting as it were the Sierra de Alcaraz, and with an inclination to the south, after having received the waters of the Guadalimar, falls into the Guadalquivir in the plains of Ubeda. The Spanish geographers place the sources of this river in two fountains, distant about seventeen miles from each other, on the Sierra de Cazorla 38° N. lat., and 3° W. long. The windings of this mountain force it at first to follow an irregular course. After having received the Guadiana-Menor, near Jodar, it flows towards the west as far as Montoro, and then to S.W., gathering all the torrents which descend from the Sierra Morena on the northern bank, and on the southern, the streams that flow from the Sierra de Bedmar, Jaen, and Cabra. The Guadajoz, which crosses the high road from Madrid to Cadiz not far from Cordoba, is one of its greatest affluents on the southern bank. At Palma del Rio it receives the Genil, and continues a W.S.W. and S.S.W. course nearly to Seville. Beyond that city it flows almost due south without any obstacle, through a level country with a winding course, and dividing itself into several branches, forms two islands, called *Isla Mayor* and *Isla Menor*, or *Great* and *Small Island*. At the southern extremity of the *Isla Mayor* these different branches rejoin, and the river enters the sea near San Lucar de Barra-meda.

The extent of country which this river traverses from the Sierra de Cazorla, lat. 36° , to the Punta de Chipiona, situated, according to the Derrotero de Tofiño, in $36^{\circ} 44' 18''$, is about 276 miles; but the course of the river, following all its windings, is at least 350 miles. The Guadalquivir is navigable as far as Seville; and a company has undertaken to remove the obstacles which impede the navigation to Cordoba. The affluents of the Guadalquivir, besides those mentioned, are the Guadiel, the Escobar, the Jandula, the Yeguas, Arenales, Guadalmellato, Guadabarbo, Bembezar, Guadalbacar, Galapagar, and Viar, which flow into it on the northern bank; and on the southern Jandulilla, Ninchez, Torres, Guadalbullon, Salados de Arjona, or salt streams of Arjona, Corbones, Guadaira, and Tagerete.

The plains of Andalusia, notwithstanding their being situated in one of the warmest climates of Europe, are still generally speaking of a moderate temperature. It never freezes in them, and the snow never remains long upon the ground. The unhealthy and scorching winds, which come from Africa, are cooled and purified by the snowy summits of the Sierra Nevada, and rarely produce those pernicious effects observable in the country from which they blow.

On arriving at Despeña Perros, on the route from Castile to Andalusia, the most inattentive observer will immediately perceive that the productions of nature are changed. On the

northern side, the Marianic range presents nothing but rosemary, cistus, and other plants indicating a parallel of latitude equal to the south of France; the southern side presents itself at once covered with mastic-trees, kermes-oak, bean-trefoil, myrtles, and other plants of warmer climates; as he descends, the lower parts are covered with the species of umbelliferous, papilionaceous, and other plants properly belonging to the Flora of Africa. From Carolina, the first of the colonies of the Sierra Morena, long and strong hedges of the American aloe form the common enclosures of the grounds. At a distance the stately palm-tree rears its lofty head above the olive, pointing out the house of the farmer or the garden of some convent. The mesembryanthemum, or fig-marigold, ornaments the dwelling of the humble inhabitant of the village, with its brilliant scarlet flower. At Seville the banana plant is found in many gardens; and exotics, which even at Montpellier require to be kept in a green-house, are here common in the open air. As we approach the sea-shore the European vegetation almost disappears, and is replaced by plants properly belonging to the Flora of Arabia, Egypt, and Barbary: the chamærops or dwarf-palm, which never rises to the elevation of a tree, occupies all the space that the husbandman has left uncultivated: the caper plant occupies all the wild and gravelly spots. The *acebuche* or wild olive-tree, and the woody astragalus, take possession of all the space abandoned by man. The sage, the gum cistus, various species of thymes, the rosemary, the myrtle, and other aromatic plants, cover the uncultivated heights. The orange and lemon trees, particularly around convents and monasteries, form groves of considerable extent, which in the time of blossoming fill the air with a delicious perfume. At that season the inhaling of so many odours, in which the balsamic perfume of the cistus is distinctly perceived, especially before and after sunset, gives a delightful sensation of the salubrity of the air. Within fifteen or twenty miles from the coast, the plants of America are so adapted to the soil as to have become almost naturalized: the nopal, on which the cochineal insect is fed, is very successfully cultivated near Cadiz; and the same plant forms the hedges of the vineyards of the Hoya de Malaga. The sugar-cane and the cotton-tree occupy the plains of Velez-Malaga, Torroja, and Motril: the pomegranate is a very common tree in all that part. With so great a variety of productions, the season of blossoming must necessarily be very long; it begins about the end of January, with the almond-tree, and ends in June with the olive. The harvests also of fruit and grains succeed one another throughout the whole circle of the year, beginning in February or March with the sugar-cane, and ending in March or April with the orange, on which tree it is not an unfrequent occurrence to find the fruit and blossom together. Even when the heat of the sun has dried up the smaller rivers, their banks are covered with the rosy flower of the adelfa, or rose-bay tree. The soil is so productive, particularly in the plains, that the husbandman with very little trouble may obtain an abundant harvest. Besides all the species of corn and fruit, wine and oil make the bulk of the productions of the soil. Among the wines, the Jerez or sherry, the Pajarete, Malaga, Montilla, Espera, Bornos, and Tintilla, are the most celebrated. The rich pastures of the mountains and valleys feed innumerable herds of cattle, among which the bulls have been renowned from the fabulous times of King Geryon. The woods of oak of the Serrania de Ronda, of Cordoba, and Granada, afford nourishment to a multitude of hogs; and the Loma de Ubeda, the Dehesa of Cordoba, and the Cartuja of Jerez, produce the finest breed of horses in the Peninsula. The seas and rivers abound in fish, and the mountains in every species of game. The wolf and the boar are the only ferocious animals; among the reptiles and insects, the scorpion, the tarantula spider, the chameleon, and some snakes, though none of the worst kind, are found. The riches of the mineral kingdom are no less abundant. Sixty-six mines are known, which produce gold, silver, copper, iron, lead, loadstone, coals, vitriol, and sulphur.

Andalusia, under the Mohammedans, included four kingdoms, viz., Seville, Cordoba, Granada, and Jaen, but at present it is divided into six provinces; Seville, Cadiz, Cordoba, Jaen, Granada, and Malaga, containing a population of 1,904,276 inhabitants; two archbishoprics, six bishoprics, fourteen collegiate churches, the same number of military commandaries, 980 parishes, 760 convents of both sexes, with 18,063 monks, and 5,624 nuns, the whole

comprised in 41 cities, 458 towns, 314 villages and boroughs. Andalusia is divided into two military departments, having each a captain-general, and a *Chancilleria*, or high civil and criminal court, one at Seville, and another at Granada.

The people of Andalusia appear to be a mixture of five different nations, which successively have had the dominion of that region,—the Carthaginians, the Romans, the Vandals, and the Goths, mixed with the original race, very probably of African origin. The Moors invaded it in 711, and it was not until 1491 that they were expelled from Granada, their last hold. Notwithstanding their expulsion, many traces of their character are still discernible. The complexion and features of the inhabitants, their dances, music, and musical instruments, many names of persons and places, the most trivial phrases, their prejudices, their system of agriculture, their hospitality, and part of the dress, especially among the women of some villages, and even their harsh mode of aspiring the Castilian language,—everything reminds the attentive observer of their Arabian ancestors. The Andalusian, inhabiting one of the finest climates in the world, where nature so liberally yields its riches, lives contented with what he possesses, is never anxious about the future, and is a stranger to sorrow. This sort of indifference and improvident disposition has caused him to be accused of indolence. The inhabitants of the plains of Seville may perhaps deserve that character; but the labourer of the Serrania de Ronda, of the Hoya de Malaga, of the Alpujarras, and in general all the people inhabiting the highlands, whom the sun when it rises always finds busied in their occupations, which they never quit until after its setting, cannot justly be taxed with indolence. In those districts the women are seen working in the fields, while the men are employed in reaping the harvest in the plains of Seville; and, when men and women work together, the former are observed to stop in their work now and then to smoke their paper cigars, while the latter, who do not enjoy that luxury, proceed in their task; which circumstance may probably have led inattentive travellers to make erroneous statements about the supposed idleness of the Andalusian people, and the miserable condition to which the women are reduced in that province. The same amount of credit is due to all the accounts and wonderful tales about the jealousy of the Andalusian men, and of the confinement in which they keep their wives. Possessing a powerful and lively imagination, the Andalusian express the most simple ideas in a figurative and energetic language, which may perhaps entitle them to the epithet of the Gascons of Spain. The *Sal Andaluza*, or Andalusian wit, though not so pungent, is not less celebrated in Spain, than the Attic wit was in Greece. The Andalusian women are remarkable for the gracefulness of their forms, for their expressive, large, and black eyes, and for their small, delicate feet. It is not, however, a rare occurrence to find among them some with blue eyes, a fair complexion, and light, flaxen hair. Andalusia has at all times produced eminent men. The great Trajan, the two Senecas, the poet Silius Italicus, and the agriculturist Columella, did honour to the Andalusian name under the Romans. The list of the eminent Arabs, who were born and educated in that province, is still more numerous; and, in modern times, the Granadas, Leones, Morillos, Cespedes, Herreras, Riojas, and also the best lyric poets in the Peninsula, were Andalusians by birth. If ever a rational and enlightened system of government should secure the property and allow the free development of the intellectual faculties of this people,—if the fixed rule of the law should ever be substituted for the caprice of man,—Andalusia will become the finest province in Spain. At present, though there are universities at Seville, Granada, and Cordoba, besides several colleges at Cadiz and other principal towns, education is not in the most flourishing condition. The unequal division of the land,—the best and largest portion of which is in the hands of the grandes, who never visit their possessions, and of monks, who care little about improving them,—keeps agriculture in a very backward state; and an oppressive and injudicious fiscal system prevents the advancement of trade and industry. (See Miñano, *Recueil de Voyages de la Société de Géographie de Paris*, vol. iii., pp. 8, 9. Antillon; Malte Brun's *Géographie*, viii., book 138. Bory de St. Vincent's *Résumé Géographique de la Péninsule Ibérique*, section i., chap. 3, section ii., p. 472—502.)

For the subdivisions of Andalusia, and the chief towns, see the names mentioned in this article.

ANDAMAN ISLANDS, a group in the bay of Bengal consisting of four islands with several islets, in 92° 30' E. longitude, and occupying a space which extends from 10° 32' to 13° 40' N. latitude. Three of these islands are so contiguous, being only separated by very narrow straits, that they are usually considered as one island, under the name of the Great Andaman, and are generally so laid down in maps. Another of these islands, which is known as the Little Andaman, is the most southern of the group. Rutland Islet lies between the two Andamans, and Great Sentinel Islet is on the western side of Great Andaman, in 11° 45' N. lat., and 92° 3' E. long. The remaining islets are not known by any distinctive names. The most northern of the Nicobar islands is within 30 leagues of the south of Little Andaman.

Great Andaman is about 140 miles long and 20 miles broad. In the centre is a high mountain called the Saddle Peak, which is about 2400 feet above the level of the sea. The island does not contain any considerable river. It is tolerably clothed with trees, several of which afford timber of sufficient size for ship-building; among them are the poplar, ebony, a tree resembling satin-wood, red-wood, the cotton-tree, and almond-tree, besides bamboos, ground-rattans, and numerous shrubs.

Very few animals are found on the islands; the principal of them is a species of small hog, which is scarce; the inhabitants use it for food. Besides these hogs, the Andamaners eat rats, guanas, and snakes, but their principal food consists of fish, of which there are many varieties, and, during the north-east monsoon, they are very abundant. The shores abound in shell-fish, and oysters of good quality are found in some situations. The edible birds'-nests, so highly prized in China, are sometimes seen in these islands, and a variety of beautiful shells—gorgonias, madrepores, and couries—may be gathered on the shores.

The fruit of the mangrove is almost the only vegetable substance in the islands that is fit for food. Cocoa-nut trees,—which are so plentiful and so prolific, both on the continent and the neighbouring islands,—have never been planted in the Andaman islands.

The inhabitants are among the very lowest in the scale of civilization of any people with which we are acquainted; they show determined hostility to Europeans, and repugnance to come into communication with them. They are small of stature, seldom exceeding five feet in height, and ill-formed, with large heads and very slender limbs. In colour, hair, and features they resemble the race of African negroes. They are wholly unaccustomed to the use of clothing; their implements are but few in number, and of a very rude description. They have no vessel that can resist the action of fire, their only mode of cooking consists in throwing their food upon burning wood. Their principal weapons of offence are bows and arrows. The former are usually from four to five feet long, and for strings they use fibres drawn from the leaf of a tree, or slips of bamboo; their arrows are formed of reeds, with heads of wood hardened in the fire, or of fish-bones. They also carry spears of heavy wood, with sharpened points, and are provided with a shield made of bark. They use both their arrows and their spears for killing fish, and show considerable dexterity in this occupation; they likewise make use of a hand-net formed of bark.

It is worthy of remark, that every people with whom we have become acquainted, however small their acquaintance with other arts, are possessed of the art of making nets of one kind or other, and thus forming articles of some utility.

The dwellings of the natives are rude in the extreme: they are formed by fixing four poles in the ground and binding their tops together, filling up the spaces between them with branches of trees, and leaving a vacancy on one side just large enough to allow of ingress and egress. In their disposition, they are described as cunning and treacherous; their disinclination to the intercourse of strangers amounts with them to a passion. They make no attempt to cultivate the soil, and are obliged to reside in the immediate neighbourhood of the sea, from which they derive the principal part of their food. The population of the Great Andaman, it is conjectured, does not exceed 2500 persons; they unite in small societies, and move about from one part of the coast to another in search of food. These people are superstitious, and are believed to worship the sun; but our imperfect acquaintance with their customs does not allow us to express any decided opinions on this subject. On awaking in the morning, their first care is to plaster their bodies

with mud, which hardens in the sun, and serves as a protection against the attacks of insects which swarm in the air, and would otherwise be a constant torment to them. This plastering, and the custom of painting their woolly heads with red ochre, does not tend to improve their naturally hideous appearance.

The origin of this race of people,—so different in their appearance and state of civilization from any of the races on the continent, or the neighbouring islands,—is an object of some curiosity. The people to whom they bear the greatest resemblance in their persons and dispositions are the mop-headed Papuas of New Guinea; but how they should have found their way to so great a distance, in their frail canoes, it is difficult to imagine. The language used by the Andamaners, as far as there are means for judging, appears to be wholly dissimilar to any spoken in other parts of the east.

A settlement was attempted by the English in 1791, on the south part of the largest island, which settlement was, two years afterwards, removed to Port Cornwallis, near the northern end, in 13° 28' N. lat., and 92° 54' E. long. One object for making this establishment was the possession of a commodious harbour on the east side of the Bay of Bengal, which might be a place of shelter during the prevalence of the north-east monsoon. The place was abandoned in 1796, in consequence of its proving extremely prejudicial to the health of the settlers. It is probable that this disadvantage might have been remedied by clearing the adjacent district, which consists of lofty hills covered with trees and jungle.

In 1814, when Port Cornwallis was visited by an English ship, very few vestiges remained of the British settlement. Subsequently (in April, 1824) the British force under Sir Archibald Campbell, despatched against the Burmese, assembled in the harbour, where some of the ships remained about a month; but it was not found possible on that occasion to establish any intercourse with the natives, who omitted no opportunity of showing their hostile feelings by discharging their arrows at all the Europeans who came within their reach.

The Little Andaman was visited, in November, 1825, by the Earl Kellie transport, for the purpose of procuring water for the troops which she was conveying to Rangoon, when the inhabitants showed an equally fierce disposition, and endeavoured as much as possible to obstruct our people while filling their water-casks. This smaller island does not possess any harbour, but has tolerable anchorage near the shore. It is twenty-eight miles long with an average breadth of seventeen miles. (Symes's *Embassy to Ava*, and MS. documents at the India Board, as quoted in Hamilton's *East India Gazetteer*.)

ANDANTE, in music, (participle of the Italian verb, *andare*, to go, *going*;) is the third in order of the five classes into which musical movement is divided, (see *ALLEGRO*;) and the medium between the extremes of slow and quick.

The music of former days, of Corelli, Handel, &c., which we agree to call ancient music, was generally much slower than that which prevails at present, and *andante* was then used to denote a moderate degree of quickness; now it indicates a steady, calm motion, rather inclining to slowness than the reverse. It also enjoins a more than ordinary attention to the measure, to the equality of time given to each bar. It must be added, however, that composers often differ from each other in the meaning they annex to this word, a want of agreement which can only be remedied by invariably marking the commencing time of all movements by the metronome, or some kind of pendulum.

This term is also used substantively: thus we say, *an andante of Haydn*, &c.

ANDANTINO, in music, the diminutive of *andante*, but whether less slow or less quick, is still a question at issue. Rousseau, Türk, Clementi, and many others, are on the slow side; Koch, Burney, and Lichtenhal, espouse the other.

When the word *andante* is used, as by the old masters, to denote a degree of quickness, its diminutive abates its motion: when employed to indicate a movement rather slow than quick, as in the present day, the diminutive increases its motion. For want of adverting to this fact, much misapprehension and some disputes have arisen. It, however, seems to be agreed, that *andantino* now shall signify a movement quicker than *andante*—that it shall be the medium between the latter and *allegretto*.

ANDELYS (LES), a town in France on the right bank of the Seine, in the department of Eure. It properly consists of two towns, Grand (great) Andely, and Petit (little) Andely; though they are usually considered as one. It is a busy place, and contains a population of 5000 (Balbi), who are engaged in the manufacture of ratteen, a coarse woollen stuff. Many apples are grown in the neighbourhood for cider. Nicholas Poussin was born in an adjoining hamlet, or in the town itself: at Little Andely there is a monument to his memory. A castle in the vicinity is said to have been built by Richard Cœur de Lion. It is now in ruins.

The arrondissement of which Les Andelys is the capital comprehends 147 communes, and contains above 63,000 inhabitants.

ANDERNACH, a small town in a pleasant country on the left bank of the Rhine, in the district of Coblenz and the province of the Lower Rhine, 50° 27' N. lat., 7° 25' E. long., and about ten miles W.N.W. from Coblenz. It has some trade, chiefly in millstones, which are cut in the neighbouring villages of Ober and Nieder-Mendig, in bricks, clay for tobacco-pipes, and in trass, which is sent to Holland. This trass (see next page) is an earth, which is pulverized and mixed with lime to make a mortar suitable for constructions under water. Trass is a corruption of the Dutch word *tiras*, which signifies cement.

In Andernach numerous pieces of columnar basalt are employed as posts at the corners of streets, &c. The door-posts and side-pieces of almost all the windows are made of the porous lava of which the famous millstones are formed. This material is also used for paving courts and kitchen floors, and has been employed in the construction of some of the oldest buildings in this town, as well as in Coblenz. There are several mineral sources near the town. The place has about 3000 inhabitants, and a gymnasium. The vine is cultivated in the neighbourhood.

Andernach was a Roman station under the name of Antunacum. It was also once an imperial town, till the year 1496, when the elector of Cologne reduced it to the rank of a municipal town.

Physical structure of the surrounding country.—Andernach lies on the border of the mountainous region called the Eifel, which stretches between the Ardennes and the Rhine, and has been the seat at one time of many active volcanoes; but all have been extinct since a period long antecedent to the historical æra. The fundamental rock of the country is grauwacke, which may be seen in many places around Andernach; the volcanic products lie upon that, all the secondary strata being wanting. Between five and six miles west of Andernach is the Laacher See, or Lake of Laach, a spot celebrated for the beauty of its scenery. It is of a circular form, and is surrounded with woods which rise from the water's edge to the summit of the high sloping banks; a man at an ordinary pace requires about two hours and a half to walk round it. The surface of the water is 670 feet above the Rhine at Andernach, and the depth is about 200 feet. It has been commonly considered as the crater of a volcano, and the circular form and igneous products scattered around lead one very naturally to view it as such; but great weight is due to the observations of the Baron Van der Wyck in his *Uebersicht der Rheinischen und Eifeler erloschenen Vulkane*, who considers the lake to be a depression in the grauwacke, and that the igneous products were ejected from five volcanoes in the immediate neighbourhood. There is no stream of lava, nor any walls of solid lava immediately adjoining the lake; the volcanic products on its shores are scorix or cinders, pumice and ashes, with numberless volcanic balls or bombs in the ashes; but solid lavas, basalts, and tuffs, are met with in all the hills and valleys around. Immediately in the neighbourhood of Andernach, and between it and the town of Mayen, there are great tracts covered with pumice stone, gravel, and ashes, often to a considerable depth; these substances are in many places covered by a yellow marly sand, containing land shells, called *loess*, and in some situations this loess is covered again with pumice stone, gravel, and ashes. Not far from the Laacher Sea are the celebrated millstone quarries of Nieder Mendig, which have been worked, it is believed, for at least 2000 years, and from which millstones are sent to every part of Europe and to America. The rock is a very hard porous lava, which in all probability was a stream from one of the neighbouring volcanoes. It is covered with the pumice

stone, gravel, and asnes, in many parts, but it is supposed to be not less than five miles in length, and nearly three miles in breadth. The quarries are all underground, and are well worth visiting from the great extent of the excavations, and the forms of the lava, which separates into gigantic columns from fifteen to forty feet in height. Five miles north of Andernach is the Brohl valley, celebrated not only for its beautiful scenery, but on account of its containing vast accumulations of an indurated volcanic mud, which by subsequent denudations has been broken into detached masses, presenting great vertical precipices and many varied picturesque forms, clothed with a luxuriant vegetation. The substance is called *trass*, and has been long extensively quarried; it is pounded and used in making mortar for buildings under water, like the volcanic substance called *puzzolana* in the neighbourhood of Naples, and the artificial imitation of it, Roman cement. Vast quantities of it are exported to Holland, where it is used in the construction of the dikes.

The volcanic district of the Lower Eifel, which is immediately adjoining to Andernach, is very accessible to those who visit the Rhine. It is extremely interesting, not only to the geologist, but to all who take pleasure in looking upon beautiful natural scenery. There is a short account of it in Dr. Daubeny's work on *Volcanoes*, and a much more detailed description in Dr. Hibbert's more recent publication on the *Basin of Neuwied*; a book, however, that will not be very intelligible either to the general reader or to any one who is not tolerably familiar with geology. The best works on the subject are in German, of which there are several. The work of Baron Von der Wyck, above quoted, is excellent, and Steininger's *Geschichte der Rheinischen Vulkane* is very full; but the best we have seen is a compilation from other writers, together with valuable additions from personal observation, by Messrs. Von Oeynhausen and Von Dechen, in the *Geographical Journal, Hertha*, for the year 1828.

ANDERSON (ADAM), was born in Scotland in 1692. Having come to London, he obtained the situation of clerk in the South Sea House, with which establishment he continued to be connected for forty years, having risen at last to be chief clerk of the Stock and New Annuities. In the charter, granted in 1732, for the establishment of the colony of Georgia in America, Mr. Anderson was appointed one of the trustees to carry that object into execution; and he also held a seat in the court of assistants of the Scotch Corporation in London. He died, at his house in Red Lion Street, Clerkenwell, on the 10th of January 1765. The chief occupation of many years of Mr. Anderson's life was the composition of his voluminous and well known work, the *Historical and Chronological Deduction of Trade and Commerce*, which was first published in 2 vols. folio, in 1762. A second edition of the same size appeared in 1764; and a third, in 4 vols. quarto, (the fourth volume being new and by a different compiler,) in 1782-9, after the death of the author. This work contains a large collection of facts; but from the author's imperfect scholarship, or his limited command of books, he has taken many of them at second-hand, from translations, or books of little authority; and in the earlier portion of his book, especially, he has nearly neglected all the best sources of information. This defect has been to a great extent remedied in what may be considered a fourth edition of Mr. Anderson's work, the *Annals of Commerce, Manufactures, Fisheries, and Navigation*, by Mr. David Macpherson, 4 vols. quarto, 1805. The last three volumes of this publication are nearly a reprint of Anderson's *Historical Deduction*; but the first, which comprehends the history of commerce down to the fifteenth century, is entirely re-written. Mr. Anderson's style, we may add, is very prolix, and singularly antiquated for the period in which he wrote; but in many of his opinions upon commercial subjects he was in advance of his age.—James Anderson, D.D., a brother of the subject of this notice, was the author of a work entitled *Royal Genealogies, or the Genealogical Tables of Emperors, Kings, and Princes, from Adam to these Times*, published in 1732; of a *Genealogical History of the House of Ivery*, in 2 vols. 8vo., Lond., 1742 (the last volume having been prepared for the press after his death, and a third being promised, which, we believe, has never appeared); of a volume entitled the *Constitutions of Free Masons*; and also, we believe, of several single sermons. He was minister of the Scottish church, Swallow Street, London; and used to be known among his acquaintances by the name of Bishop Anderson. (See Chalmers's *Biograph. Dict.*)

ANDERSON (ALEXANDER), a native of Aberdeen, in Scotland, who in the beginning of the seventeenth century, while yet a young man, appears to have settled as a private teacher of the mathematics in Paris. Neither the year of his birth, nor that of his death, is known. He is the author of the following works: *Supplementum Apollonii Redivivi*, quarto, Paris, 1612; *Ἀππολλογία, pro Zeteticis Apolloniani Problematis a se jam pridem edito in Supplemento Apollonii Redivivi*, quarto, Paris, 1615; *Ad Angularium Sectionum Analyticarum Theoremata καθολικώτερα, a Francisco Vieta Fontenæensi primum excogitata, at absque ulla demonstratione ad nos transmissa, jam tandem demonstrationibus confirmata*, quarto, Paris, 1615; *Vindiciæ Archimedis*, quarto, Paris, 1616; *Exercitationum Mathematicarum Dicas Prima*, quarto, Paris, 1619. All these works are very scarce. Mr. Anderson also appears to have been selected by the executors of the eminent Vieta, who died in 1603, to superintend the publication of his unprinted manuscripts. Two treatises of Vieta, accordingly, entitled *De Equationum Recognitione et Emendatione*, appeared at Paris, in quarto, 1615, with a dedication, preface, and appendix, by Anderson. Mr. David Anderson of Finshaugh, a brother (other authorities say, a cousin) of this Alexander Anderson, was the father of Mrs. Gregory, the wife of the Rev. John Gregory, minister of Drumoak, in Aberdeenshire, whose son was the celebrated James Gregory, the inventor of the reflecting telescope. James Gregory is said to have been initiated in mathematical science by his mother. Of the same family, probably, was an Alexander Anderson, a native of Aberdeen, who graduated Doctor of Medicine at Leyden, in 1717. His inaugural discourse, which is entitled *De Morbis Acutis Puerperarum*, is remarkably thick sown with scriptural and classical quotations. (See Chalmers's *Biog. Dict.*, and Brewster's *Edin. Encyclop.*) In the Supplement to the *Encyclopædia Britannica*, there is a notice of Alexander Anderson by the late Professor Leslie, in which warm praise is bestowed upon the ingenuity, cleverness, and classic elegance of his works.

ANDERSON (SIR EDMUND), an eminent lawyer of the sixteenth century, in the early part of which he was born at Broughton, or, as other authorities state, at Hixborough, in Lincolnshire. His father, Thomas Anderson, Esq., was a gentleman of good estate; and the family was of Scotch descent. Edmund, who was a younger son, was educated at Lincoln College, Oxford, after leaving which he entered of the Inner Temple, and, having in due course been called to the bar, passed through the usual promotions, until, in 1582, he was made chief justice of the Common Pleas. This high office he held till his death, on the 1st of August, 1605. Chief Justice Anderson was one of the ablest and most learned of Queen Elizabeth's judges; but he was also one of the most rigid of the high prerogative lawyers of that time. He particularly distinguished himself by the zeal which he showed in favour of the established church, and the unwise harshness with which he endeavoured to put down dissent. We should scarcely, indeed, be going too far in saying of him that he was accustomed to regard law more than reason, and the will of the sovereign more than either. He seems, by his severity, to have made himself unpopular and odious with all parties. His printed works are *Reports of Cases argued and adjudged in the time of Queen Elizabeth, in the Common Bench*, folio, Lon. 1644; and *Resolutions and Judgments on the Cases and Matters agitated in all the Courts of Westminster, in the latter end of the reign of Queen Elizabeth*, quarto, Lond. 1653. Both books are reckoned of great authority. Three families, descended from this chief justice, through two of his sons, received baronetcies in the reigns of Charles I. and II.; and by his four daughters, who lived to be married, he became the ancestor of the earls of Pontefract, the Sheffield, dukes of Buckinghamshire, the earls of Warrington, and the lords Monson. (*Biograph. Brit.*)

ANDERSON (GEORGE), was born at Tunstern, in the duchy of Sleswick, in Germany, about the beginning of the seventeenth century. He appears to have been in a great degree self-educated. In 1644 he left his native country to travel in the East, from which he returned in 1650, after having visited Arabia, Persia, India, China, Japan, Tartary, Mesopotamia, Syria, and Palestine. He was then taken into the service of the Duke of Holstein-Gottorp, who often pressed him, but without success, to publish an account of his travels. At last the stratagem was resorted to of placing Adam Olearius behind the tapes-

try of a room in the palace, while Anderson, who was very communicative in conversation, was led to relate his adventures to the duke; and in this way the whole story was from time to time got out of him and committed to writing. He was afterwards prevailed upon to revise the manuscript, after which it was published in folio, at Sleswick, in 1669, under the care of Olearius. Anderson's travels, we believe, have never been translated into English. (See *Biog. Univ.*)

ANDERSON (JAMES) was born at Edinburgh on the 5th of August, 1662; his father, the reverend Patrick Anderson, was one of the ministers of that city. Having been educated for the law, he was admitted a writer to the signet in 1690. In 1705 he made his first appearance as an author by the publication of *An Essay showing that the Crown of Scotland is Imperial and Independent*; being an answer to W. Atwood's tract, entitled the *Superiority and direct Dominion of the Imperial Crown and Kingdom of England over the Crown and Kingdom of Scotland*, which had appeared the preceding year. As the subject discussed was one in which the people of Scotland at that moment took a very warm interest, the parliament, besides bestowing upon Anderson a pecuniary reward for his performance, ordered its thanks to be publicly returned to him by the lord chancellor, in the presence of her majesty's high commissioner and the estates; Atwood's book being at the same time ordered to be burnt by the common hangman. Anderson was further honoured by the commands of the parliament to collect and publish such antient documents as he might deem to be illustrative of the national independence; and an assurance was given that the cost of the undertaking would be defrayed from the public treasury. He therefore relinquished his profession, and in 1707 came to London to superintend the engraving of the plates for his intended work. Before it issued from the press, however, he was carried off by a stroke of apoplexy, on the 3d of April, 1728. The editing of the work was then entrusted to Thomas Ruddiman, the learned grammarian; and it at length appeared at Edinburgh in 1739, in the form of a magnificent folio, with the title of *Selectus Diplomatum et Numismatum Scotiæ Thesaurus*. An elaborate preface was prefixed by Ruddiman. Anderson held the situation of postmaster-general for Scotland from 1715 to 1717. He also published at Edinburgh, in 1727, *Collections relating to the History of Mary Queen of Scotland*, in 4 volumes, quarto. Although Anderson's name is prefixed to the *Diplomata* as the author of the publication, the credit to which he is entitled is very inconsiderable. The plates, which are well executed, are of course the work of the engraver, with the exception of those which contain explanations of the abbreviated characters; and all the rest of the book, comprising the valuable preface of 85 pages, the chronology of Scottish history, the explanations of the plates, the tables of geographical, and other proper names, is by Ruddiman. (See Chalmers's *Biograph. Dict.*, and Geo. Chalmers's *Life of Ruddiman*, p. 151, &c.)

ANDERSON (JAMES, LL.D.) was born, in 1739, at the village of Hermiston, near Edinburgh, where his forefathers had been farmers for several generations. He very early showed a great love of reading, and having, in consequence of the loss of both his parents, taken the management of the family farm into his own hands at the age of fifteen, he soon after began to apply himself to the study of chemistry, with the view of availing himself of that science in his agricultural pursuits. His adoption of various improvements in husbandry, which had never before been introduced into the district where he lived, afforded other evidences of his superior intelligence. In 1763 he left his native place, and settled in Aberdeenshire, on a farm called Monkshill, consisting of 1300 acres of land almost wholly in a wild state. It was while residing here that he made his first attempt as a public writer in a series of essays on Planting, which he contributed, in 1771, to the *Edinburgh Weekly Magazine*, under the signature of Agricola. These essays he collected and published together in 1777. From this time both his communications to periodical works and his separate publications were very frequent. In 1780 the degree of Doctor of Laws was bestowed upon him by the university of Aberdeen. Three years after he left Monkshill, and came to reside in Edinburgh. In 1784, in consequence of a pamphlet which he had printed on the Encouragement of the National Fisheries, a subject which he had some years before discussed at greater length in a quarto volume, he was employed by government to make a

survey of the western coast of Scotland, with a reference especially to that object. In 1791 he commenced the publication of a periodical miscellany under the name of the *Bee*, which had great success. In consequence, however, of a disagreement with the publishers, it was dropped in 1794. In 1797 Dr. Anderson came to take up his residence in the neighbourhood of London; and, in April 1799, he established here a new periodical under the title of *Recreations in Agriculture*. It was continued till March, 1802, when it ceased with the completion of the sixth volume. Dr. Anderson died on the 15th of October, 1808, having been for some years before much broken down through the effects of the intense literary labour of many years. The list of his numerous publications attests the extraordinary activity of his mind; and most of his writings evince great fulness of thought, extensive and varied information, and some of them no slight degree of ingenuity and originality. Dr. Anderson is now acknowledged to have been the first who propounded the theory of the origin and progressive increase of rent, which was almost simultaneously reproduced in our own day by Mr. Malthus and Sir Gilbert (then Mr.) West, and is commonly distinguished by the name of the late Mr. Ricardo, who is known to have been in possession of it two years before the publications of these writers appeared, and by whom also it was afterwards elaborately illustrated. Anderson's statement of the doctrine is to be found at p. 401 of the eighth volume of his *Recreations in Agriculture*, published in 1801. It is as perspicuous, accurate, and complete an exposition of this view of the question as any that has been since given. There can be no question also that to the zeal and labours of Dr. Anderson, much more than to any other individual, is owing the greatly increased attention to the subject of agriculture which, in Scotland especially, has grown up since he began to write. In this way he has been a distinguished benefactor to his country. A complete catalogue of his writings may be found in the authorities quoted below. They consist of between twenty and thirty separate works, besides numerous contributions to the *Encyclopædia Britannica*, the *Monthly Review*, and various other periodicals. To the first edition of the *Encyclopædia Britannica* he contributed the articles Language, Monsoons, and Sound. Among his other works are, a *Practical Treatise on Chimneys*, duodecimo, 1776.—*Free Thoughts on the American Contest*, octavo, 1776.—*Essays relating to Agriculture and Rural Affairs*, octavo, 1777.—*Observations on Slavery*, quarto, 1789.—*Two Letters on a Universal Character*, octavo, 1795.—*Selections from Correspondence with General Washington*, octavo, 1800.

ANDERSONIAN INSTITUTION. [See GLASGOW.]

ANDES, the general name given to the great range of mountains which runs along the western side of the continent of South America. In the languages of the Incas, these mountains are called *Antis*, and as they abound in copper and other metals, Humboldt is of opinion that the name is derived from the Peruvian word *anta*, which signifies copper, and metal in general. We apply, in Europe, the term Andes to the whole range, but it is unknown to the inhabitants of the countries north of the equator. These mountains are called by the Spaniards, Cordilleras de los Andes, or the Chains of the Andes, whence the word Cordilleras alone is sometimes applied to them.

In considering these mountains as a great feature in the physical structure of the earth, we may fix their southern extremity in the rocky islands of Diego Ramirez, off Cape Horn, in lat. 56° 30' south, and their northern termination in the 69th of north latitude, at the mouth of the Mackenzie River. There is probably an almost unbroken chain throughout the whole of that vast space, which is more than one-third of the circumference of the globe. It is difficult to say where the real chain of the Andes commences. It continues, however, when once formed, without a break, to the mouth of the river Atrato, or the isthmus of Darien, which pours its waters into the Caribbean Sea, in lat. 8° 15' north, a distance, reckoning the whole line, from Diego Ramirez, of 64° 15' of latitude.

The Andes of South America, although, in our maps, they look like one long, single ridge, are by no means so, but are composed of a series of chains of mountains, more or less parallel, inclosing vast elevated plains, or table-lands, and of several great groups, like knots or articulations, at distant intervals. The average width of their base is extremely narrow, considering their great length, in comparison with that of most other extensive systems of mountains; for, ex-

cept where the groups just mentioned occur, the breadth varies only from sixty to seventy miles. The greatest extension, from east to west, is between the parallels of 15° and 18° south, in one of the groups, where a base line perpendicular to the axis of the chain would be nearly 400 miles in length.

The whole surface of South America is broken by four great systems of mountains, viz., the Andes; the mountains of Venezuela, running nearly at right angles to the Andes, and parallel with the Caribbean Sea; the mountains of Parime or Guiana, on the eastern side of the continent, between the rivers Orinoco and Amazon; and the mountains of Brazil, between the Amazon and the Rio de la Plata. The proportion, however, of mountain to plain is not greater than as one to four. The Andes contain 58,900 square leagues, and rise like a vast wall along the western side of the continent, separating the plains drained by the Orinoco, Amazon, and Rio de la Plata, which occupy a space of 424,600 square leagues, from the narrow country between their western base and the Pacific Ocean, which does not contain more than 20,000 square leagues. For the convenience of description, we shall divide the range of the Andes into four parts, marked by the political divisions of the continent, and shall call them the Andes of Patagonia, of Chili, of Peru, and of Colombia.

The *Andes of Patagonia* extend from the fifty-sixth to the forty-second degree of south latitude, or about 970 miles. Cape Horn, which may be seen distinctly at sixty miles' distance, is estimated to be about 3000 feet high. The greatest heights in the largest of the three chief islands (King Charles's South land), composing the Tierra del Fuego, lie about the centre of the strait of Magalhaens: Mount Sarmiento is covered with snow all the year. According to Captain King, the line of perpetual snow in the straits is about 3500 or 4000 feet above the sea. Between Chiloe and the strait of Magalhaens the average height of the mountains does not exceed 3000 feet, though, according to Captain King, there are some which may be five or six thousand feet high.

South of the parallel of 40° , the Andes, instead of leaving a belt of land between their base and the sea, press close on the ocean, and thus assume a new character which they retain to the very extremity of the continent, when we consider, as we ought to do, that their line of continuity must be looked for in the islands of the south-west coast. North of 40° , we find a 'long unbroken shore, affording neither shelter for vessels nor landing for boats; but to the southward of that parallel, the waters reach to the very base of the great chain of the Andes, and flowing, as it were, into the deep ravines that wind through its ramifications, form numerous channels, sounds and gulfs, and, in many instances, insulate large portions of land.' (Capt. King.) The charts of the Tierra del Fuego, and of the south-west coast of America, made during the late survey under Captain King, enable us to form a more correct notion of the Patagonian Mountains, and somewhat to rectify former delineations and descriptions of them. Without entering at present on a particular consideration of the mountains of Tierra del Fuego, which require a separate examination, we may trace from the bottom of Admiralty Sound (in King Charles's Land), rugged and snow-covered mountains, running in a general westerly direction, till we come to Mount Sarmiento ($54^{\circ} 25'$ S. lat.) on the east side of Magdalen Sound, rising to the height of 6800 feet, and covered with perpetual snow. Mount Sarmiento belongs to the mountains that skirt the south side of the Gabriel channel; the whole are supposed to be the most elevated land in the Tierra del Fuego. An extensive glacier surmounts this range that runs along the Gabriel channel.

The extreme point of the South American continent, Cape Froward, ($53^{\circ} 53' 43''$ S. lat., $71^{\circ} 14' 31''$ W. long.,) rises abruptly from the sea and terminates Brunswick Peninsula, which is a mass of high mountainous land, attached to the continent by a narrow neck of low country. It appears that the Strait of Magalhaens, from Cape Virgins westward to the isthmus of the Brunswick Peninsula, following the northern shore of the mainland, exhibits undulating hills, plains with level-topped land rising from them, and extensive levels frequented by the guanaco and the ostrich, but no mountains. Thus we see that the Pampas extend to the very verge of the strait. No rivers enter this part of the strait from the mainland. If we cross the isthmus of Brunswick Peninsula westward into the Otway, and then into the Skyring water, we find both these

waters bounded on the north by low land, and no mountains visible. The Cordillera of the Andes, therefore, does not terminate in the mainland; we must look for it in that strange assemblage of large and small islands, intersected by almost countless channels, which run northward from the Tierra del Fuego, and form a broad belt in front of the Patagonian coast as far as the Peninsula of the Three Mountains. We must trace them also in the deep indentations and fjords, by which the sea enters far into the mainland, and gives to this part of the South American coast a character resembling that of the coast of Norway.

From Mount Sarmiento, a line drawn about N.W. by W. over numberless inlets, snow-topped mountains and glaciers, brings us to the southern part of Queen Adelaide's Archipelago. Ascending to Smyth's channel, between this Archipelago on the west, and King William IV.'s Land on the east, we find Mount Burney ($52^{\circ} 20'$ S. lat.) on the right side of the channel, rising to the height of 5800 feet. The slope from the base northward towards the Ancon sin Salida of Sarmiento, appears as an extensive glacier. Mount Burney is near the southern entrance of the opening called by Sarmiento 'Ancon sin Salida,' which forms the inlet to those numerous sounds and canals, by which the sea runs into the mainland, behind the Archipelago and islands that line the western coast. The first great channel which runs nearly due north, called the Canal of the Mountains is, in fact, a longitudinal valley of the Cordilleras. It is forty miles long, with an average breadth of one mile and a half, bounded on each side by the lofty snow-capped Cordilleras. The western side is much the higher, and has a glacier twenty miles long running parallel to the canal. The southern part of the glacier commences about 52° S. lat.

Due east of the Canal of the Mountains, and separated from it by intervening sounds and highlands, we find the east shore of Disappointment Bay, to which also access is obtained by the Ancon sin Salida. The east coast of this bay is flat and low, and the land runs eastward in extensive plains covered with herds of deer. Thus we see that the Cordillera in the lat. of 52° does not appear, strictly speaking, on the mainland. To trace with accuracy the course of the mountains farther north is impossible, for want of more precise information; but we must remark that the extreme western shore of the islands which cover this coast is often rocky and mountainous. Cape Isabel ($51^{\circ} 51'$ S. lat.), Cape Santiago, the S.W. entrance of the Madre di Dios Archipelago, and Cape Three Points, the N.W. point of the island of Madre di Dios, are bold projecting masses. Cape Three Points ($50^{\circ} 12'$ S. lat.) is a lofty rocky mountain, with an elevation of near 2000 feet, rising into peaked summits. Cape Primero ($49^{\circ} 50'$) is the S. point of the mountainous island of Corso, the land of which in clear weather may be seen for ten leagues from the southward. All these points are remarkable projections of the western Patagonian coast; for we must consider the parts that face the ocean as the real coast line, which is of a bold and rocky character, and broken up into an infinite number of fragments by the waters that penetrate deep into the interior and insulate large masses of the higher lands.

As we advance north from Disappointment Bay, it appears that the Cordilleras begin to get a footing on the mainland, which is shown by the high land observed on the east side of the gulfs and sounds, and by the numerous glaciers that sometimes run along their east sides, and sometimes are found at the termination of the long creeks and inlets. These glaciers are marked in the charts as occurring at numerous points along the eastern shores of the deep inlets, from the great Canal of the Mountains as far as Kelly Harbour (47° S. lat.), a little south of the San Tadeo River in the Gulf of Peñas. We may form some idea how close the Andes still press on the ocean even here, by the fact that Kelly Harbour is surrounded by lofty mountains, from 1400 to 1800 feet high, and by ice-filled valleys and ravines. A few birds and hair seals, but no trace of man or any other animal, was seen in this dreary place. A little north of Kelly Harbour is the San Tadeo river, which, though only navigable for eleven miles, is the largest river of the coast, south of the archipelago of Chiloe. The glaciers, no doubt, pour into the creeks and inlets abundance of fresh water, but are not far enough removed into the interior to give birth to rivers.

From the southern extremity of Wellington Island ($50^{\circ} 5'$ S. lat.), which is the largest island that lines this coast, being about 138 miles long, a range of high land runs

northward into the island. The highest point, called Cathedral Mount, from its resemblance to the spire and body of a church, may be seen at the distance of twenty leagues. It appears probable, then, that the Cordilleras here, as well as in their more northern course, consist of various parallel chains, running generally north, and forming, by the depressions and channels between them, a series of low lands, valleys, and channels into which the sea has penetrated.

Those who have not the opportunity of seeing Captain King's charts, and his book of sailing directions, will find a good general description of this coast by the same officer, in the *London Geographical Journal*, Vol. I.

The circumstance of mountains in this part of the Andes being covered with perpetual snow does not afford any certain guide for determining their height, if compared with mountains within the same latitudes in Europe, such as the Pyrenees and the Alps; because the limit of perpetual snow descends as we approach the pole much more rapidly than it does in the northern hemisphere. Thus, in the island of Georgia in the Southern Ocean, which is situated between the fifty-third and fifty-fourth parallels of latitude, corresponding to the latitude of central England, the line of perpetual snow comes down to the sea-shore, rendering the island, which is ninety miles long and thirty broad, wholly uninhabitable.

The *Andes of Chili* lie between the forty-second and twenty-fourth degrees of latitude, an extent of about 1200 miles. No accurate measurements have been made of the loftier summits, and all we know on this subject is very vague. Tupungato, in lat. $33^{\circ} 24'$, is considered the highest point of this part of the Andes, and no snow can be seen on its summit during certain periods of the year. Now Humboldt estimates the limit of perpetual snow in latitude 33° at 12,780 feet; and if this be correct, Tupungato cannot be the highest point in the Andes of Chili, for the pass of El Portillo, by the barometrical measurement of the author of the article Chili, in the *Encyclopædia Britannica*, is 14,360 feet above the sea. That same author supposes this part of the Andes to rise as high as 17,000 feet. South of Tupungato, in latitude 35° , there is another lofty mountain called El Descabezado, which probably got its Spanish name (signifying *beheaded*) from its truncated summit, on which there is a plain six miles in diameter.

There are several passes across the ridge, the most important of which are those on the great line of road between the city of Buenos Ayres and the port of Valparaiso on the Pacific. These mountain-passes lie between the city of Mendoza in the eastern plain, and Santiago, the capital of Chili. From Mendoza, which, according to the measurements of Bauza and Espinosa, quoted by Humboldt, is 700 toises or 4486 English feet above the level of the sea, to La Cumbre, (that is, the summit,) the road ascends to the height of 12,700 feet, and from thence there is a gradual descent to the city of Santiago, which is 2614 feet above the Pacific.

Between the thirty-third and twenty-fourth degrees of latitude, two great mountain-chains form as it were buttresses on the eastern side of the range, being the most southerly of those articulations we have spoken of. The one, called the Sierra de Cordova, lies between the thirty-third and thirty-first degrees of latitude, advancing like a promontory into the pampas (plains) of the Rio de la Plata, as far as the sixty-fifth degree of longitude; the other, called the Sierra de Salta, which has a general direction parallel to the other, lies between the twenty-eighth and twenty-fourth degrees of latitude, and extends eastward to the sixty-fourth degree of longitude, or about 400 miles from the axis of the Andes. In neither of these offsets do the mountains rise to any considerable elevation.

In the Chilian Andes the steep face is on the eastern side, to which there is not a progressive ascent, as on the western side from the Pacific.

Between the western foot of the Andes of Chili and the sea, the face of the country is diversified with several low ridges of hills, gradually diminishing in height as they come nearer the coast, and intersected by the numerous streams which flow from the mountains. Some of these are branches from the central ridge, others run parallel to it, but the highest do not exceed 2500 feet above the sea. The breadth of the Andes in this part of their course is very various: the broadest part is between Mendoza and Santiago, and it is probably not less than 140 miles.

The *Andes of Peru* comprehend that part of the range

between the twenty-fourth and sixth degrees of south latitude, a space of about 1250 miles. Their southern extremity is situated in the modern republic of Bolivia, which includes the antient provinces of Upper Peru. The great mountain-system, from the straits of Magalhaens to the parallel of Arica, in $18^{\circ} 28'$ S. lat., has a uniform direction from south to north, never deviating more than five degrees east; but from that point it turns suddenly to the N.W. and continues in the same direction until it reaches the fifth degree of latitude, when it again suddenly changes to N.E., the line of coast following the inflections of the mountains; thus the northern extremity of the Andes of Peru lies two degrees of longitude west of the southern termination. Between the nineteenth and twentieth degrees of latitude, not far from the city of Potosi, the range separates into two great branches, now called the Eastern and Western Cordilleras of Bolivia. The eastern Cordillera continues in a northerly course, with an inclination to the west, for about 500 hundred miles, terminating in a plain watered by the Paro, one of the great feeders of the Amazon; and in this Cordillera the Andes attain their greatest elevation. Chimborazo, about 80 miles south of the city of Quito, was long considered to be the loftiest point in the whole range, being, according to Humboldt, 3350 toises, or 21,436 feet above the level of the sea; but if the trigonometrical measurements of Mr. Pentland are to be relied on, there are two mountains in the eastern cordillera of Bolivia which are considerably higher, viz. the Cerro Nevada de Illimani, eastward of the city of La Paz, which is 24,350, and the Cerro Nevada de Sorata, which is 25,250 feet above the sea.

We have mentioned the two great buttresses of the Andes of Chili, the Sierra de Cordova and the Sierra de Salta; a third, and one of far greater extent, occurs between the twenty-second and seventeenth degrees of latitude, called the Sierra Nevada de Cochabamba. It constitutes a great lateral branch, which separates from the main range of the Andes, between the cities of La Paz and Oruro. The general direction of the mountains composing this vast group is from west to east, and they form on this part the water-shed of rivers which run on one side into the Amazon, on the other into the Rio de la Plata. Their eastern slope is very rapid, and their most lofty summits exceed the limit of perpetual snow, which is here 14,700 feet above the sea, and these are situated in the northern part of the group. Between the fourteenth and fifteenth degrees of latitude the eastern and western Cordilleras of Bolivia unite, and form the great mountain-group of Cuzco. By the bifurcation and this subsequent reunion of the range, a vast table-land is inclosed at an elevation of 12,700 feet above the sea, containing an area of 3500 square leagues, covered with fruitful fields and populous towns. It contains the great Lake of Titicaca, the surface of which extends over 448 square leagues, and, according to Humboldt, is more than twenty times as large as the Lake of Geneva. This table-land or basin is inclosed on every side, and there being no outlet, the waters which flow down from the surrounding mountains into the lake must be carried off solely by evaporation from its widely-extended surface.

The group of Cuzco, so called from the city of that name, on its eastern boundary, is by far the most extensive of those lateral assemblages of mountains which occur at intervals along the eastern side of the Andes, having an extent of surface three times as large as the whole of Switzerland, and with a mean height of 8300 feet. Proceeding N.W. from this group, a second bifurcation of the range takes place, near the thirteenth degree of latitude, the eastern chain extending eastward of the city of Guanta, the western holding a course to the west of Guancavelica. They unite again between the tenth and eleventh degrees of latitude, to form the group of Pasco, inclosing another basin, or rather table-land, having an elevation of nearly 11,000 feet above the sea, but not one-half so large as the table-land of Titicaca. In the western chain there are two mountains covered with perpetual snow, called Toldo de la Nieve, (tent of snow,) which are seen from the city of Lima. North of the group of Pasco, the Andes divide into three parallel branches, or subordinate chains, which continue to the frontiers of Colombia, where they unite again in the group of Loxa, about the fifth degree of latitude. The eastern and central chains are of comparatively low elevation, for in no part of their course do they attain the limit of perpetual snow; but the western chain, which runs along the coast, has the three snow-clad summits of Pelegatos, Mojo-

pata, and Huaylillas. Between this last mountain, situated near Guamachuco, in latitude $7^{\circ} 55'$, and Chimborazo, a distance of more than 400 miles, the Andes rise in no part to the height of the perpetual snow limit. Between the mountain-range and the western ocean, the low country of Peru is very narrow, rarely exceeding 50 miles.

The *Andes of Colombia*.—At the northern limit of the group of Loxa, between the third and fourth degrees of south latitude, the main range divides into two subordinate chains, or cordilleras, which inclose the longitudinal valley of Cuenca by their uniting in latitude $2^{\circ} 27'$ to form the group of Assuay, which last contains a table-land, or plateau, at an elevation of 15,520 feet, almost within the region of perpetual snow. Beyond this group another bifurcation takes place, the eastern cordillera containing the great mountains of Chimborazo (21,415 feet) and Yliniza (17,386); the western cordillera containing the mountains of Sangay and of Cotopaxi (18,858). The chains unite in the narrow ridge of Chisinché for a short distance, but spread out again shortly afterwards to form the vast table-land of Quito, which is bounded by stupendous mountains on the east side, and is inclosed by the reunion of the chains at the volcano of Imbabura, in latitude $0^{\circ} 20' N.$, near Villa de Ibarra. In the eastern cordillera are the mountains of Antisana (19,126 feet) and Cayambe (19,625); in the western, are Pichincha (15,924) and Cotochache (16,428). These chains inclose a table-land, which is divided longitudinally by low hills, and on the east of these are the plateaus of Puembo and Chillo; on the west, those of Quito, Inaquito, and Turubamba. The equator passes through a village in the valley of Quito. In no part of the Andes are there so many colossal mountains brought together as on the east and west of this vast table-land of the province of Quito, one degree and a half to the south, and a quarter of a degree to the north of the equator.

The reunion of the cordilleras near Villa de Ibarra forms the group of Los Pastos, north of the table-land of Quito, in which are situated the volcanos of Cumbal, Chiles, and Pasto. The general direction of the Andes from the northern extremity of the table-land of Quito to the neighbourhood of the city of Popayan, changes from $N. 5^{\circ} E.$ to $N. 36^{\circ} E.$, following the direction of the coasts of Esmeraldas and Barbacoas. North-east of the city of Almaguer, the great range again divides, and the subordinate chains do not unite again. The eastern branch spreads out to form the group called Paramo (desert) de las Papas, in which are situated the sources of the Magdalena, and its tributary the Cauca; and in latitude $2^{\circ} 5'$, this group sends off two branches, by which we have the Andes now divided into three subordinate chains, viz., the eastern and central cordilleras of New Granada, springing from the Paramo de las Papas, and the western cordillera of New Granada, which has continued in an unbroken ridge from the bifurcation of the main range near the city of Almaguer. The eastern cordillera extends towards Santa Fe de Bogota and the Sierra Nevada de Merida, east of the Magdalena river: the central cordillera runs parallel with the eastern to the fifth degree of latitude, forming with it the sides of the valley of the Magdalena, and it continues to divide that river from the Cauca until their junction in latitude $9^{\circ} 23'$. The western cordillera separates the valley of the Cauca from the low country of Choco, which last forms the eastern shores of the gulf of Panama. In the central cordillera is the celebrated pass of Quindiu, between the cities of Santa Fe de Bogota and Popayan. Between the second and fifth degrees of latitude there are many places where the mountains rise above the region of perpetual snow; the most elevated are the Pic de Tolima, in latitude $4^{\circ} 46'$, which is 18,314 feet, and is the highest point in the range of the Andes north of the equator. But, in no part of the eastern cordillera, within the same degrees of latitude, is there any height which exceeds 12,700 feet; in latitude $5^{\circ} 50'$, however, there are the snowy summits of Chita, and in latitude $8^{\circ} 12'$ those of Muchuchies, and it is only in this eastern cordillera that any mountains rise to the perpetual snow limit beyond the fifth degree of latitude. The slope of this cordillera is extremely rapid to the east, where it bounds the basin of the Meta and Orinoco, but on the western side there are several abutments, in the form of great plateaus, or table-lands, and on these are situated the cities of Santa Fe de Bogota, Tunja, Sogamoso, and Leira. They have an elevation of from 8300 to 9000 feet. The western cordillera of New Granada is low, compared with the eastern and central,—the highest point, the Pic de Torra, situated S.E. of the city of Novita, not

rising to the limit of perpetual snow. There is a gradual fall of the chain to the mouth of the Atrato on the Caribbean Sea, where there is a complete termination of the great mountain-range of South America; between Cupica, a small sea-port in the province of Biruquete, on the Pacific, and the Rio Naipi, which falls into the Atrato 45 miles above its mouth, there is nearly a dead flat, at least the plain is unbroken by any perceptible ridge.

The range of the mountain-system of the Andes may be said to terminate towards the east, where the eastern cordillera of New Granada, or what has been called the Andes of Cundinamarca, form the Sierra Nevada de Merida; but they are united to the mountains, which run from west to east along the coast of Caracas, or Venezuela, by the four Paramos of Timotes, Niquitao, Boconó, and Las Rosas, which are from 8000 to 10,000 feet high. The mountain-system of Venezuela extends 500 miles, from the Andes of Cundinamarca to the gulf of Paria, and, like the great range of the Andes, is composed of a series of parallel chains inclosing longitudinal valleys, or table-lands, at great elevations. The Silla de Caraccas is the loftiest point, and rises 8630 feet above the sea. [See AMERICA.]

North of the central cordillera of New Granada, and in the midst of a great plain which extends from the delta of the Rio Grande de la Magdalena to the sea lake of Maracaybo, there rises a vast insulated group of mountains called the Sierra Nevada de Santa Marta. They extend about 45 miles from west to east, and their highest summits—El Picacho and La Horqueta—rise beyond the limit of perpetual snow. No exact measurements of these heights have been made, but Humboldt estimates the most elevated to be 19,000 feet above the level of the sea.

The higher regions of the Andes present themselves under three different forms:—the active volcanos, such as Cotopaxi, which have only one crater of vast dimensions, are conical mountains, with summits more or less truncated. Those which have been torn by a long succession of eruptions have a jagged outline, being composed of numerous sharp points, like what are called needles in the Alps. The third is the rounded form, like Chimborazo, the most majestic of all, which, when seen from the Pacific, in a clear state of the atmosphere, stands prominently out from all the surrounding mountains, and towers proudly on the coast of the Andes, like the dome of St. Peter's looking down upon the antient monuments of the Capitol. The Andes appear as a chain only when seen from a distance. When we are placed within the range, as in the table-land of Quito, we see an assemblage of insulated mountains rising from the plateau. Thus all those volcanic peaks, such as Pichincha, Cayambe, and Cotopaxi, although they have separate names, constitute, for more than half their height, one mass, but they appear to the inhabitants of the table-land of Quito as distinct mountains rising out of a plain. The great elevation of such table-lands makes it difficult to believe the height of the mountains to be so considerable. Thus Chimborazo is 273 feet less in elevation above the plateau from which it rises than the summit of Mont Blanc is above the valley of Chamouni, and mountains, which would astonish us by their height if they rose at once from the sea shore, look like low hills on the Cordilleras. Humboldt and Bonpland endeavoured, but without success, to reach the summit of Chimborazo; they ascended, however, to the height of 19,280 feet,—a greater elevation than had ever been trod by man in any part of the world, and 3546 feet higher than the top of Mont Blanc.

Among the majestic and varied scenes which the Cordilleras present, says Humboldt, the valleys produce the most striking effects upon the imagination of the European traveller. The enormous height of the mountains cannot be seen as a whole except at a considerable distance, and when we are in the plains which extend from the coast to the foot of the central chain. The table-lands which surround the summits covered with perpetual snow are, for the most part, elevated from 8000 to 10,000 feet above the level of the ocean. That circumstance diminishes to a certain extent the impression of grandeur produced by the colossal masses of Chimborazo, Cotopaxi, and Antisana, when seen from the table-lands of Riobamba and Quito. But it is not with the valleys as with the mountains: deeper and narrower than those of the Alps and Pyrenees, the valleys of the Cordilleras present situations so wild as to fill the mind with fear and admiration. They are formed by vast rents, clothed with a vigorous vegetation,

and of such a depth that Vesuvius might be placed in them without overtopping the nearest heights. Thus, the sides of the celebrated valleys of Chota and Cutaco are 4975 and 4225 feet in perpendicular heights; their breadth does not exceed 2600 feet. The deepest valley in Europe is that of Ordesa in the Pyrenees, a part of Mont Perdu; but this, according to Ramond, is not more than 3200 feet deep.

The Andes contain the sources of the greatest rivers of the world, the Amazon, and the La Plata, besides many others of considerable extent, such as the Magdalena and Orinoco; but on the western side of the continent, owing to the proximity of the mountains to the sea, there is no river of any magnitude.

GEOLOGICAL STRUCTURE.—We are indebted for nearly all the information we possess on this subject to the Baron Alexander Von Humboldt, but, for reasons which we shall presently show, what he has told us conveys little more than a general knowledge of the existence of certain classes of rocks and minerals. When that illustrious traveller left Europe to visit South America, geology was in a very different state from that in which it now is. He had been educated at Freyberg under Werner, in a school where mineralogical characters were too exclusively dwelt upon as a principal test for determining the ages of rocks, and where theoretical opinions, founded on extremely limited observations, prevailed too much. The organic remains contained in the strata were treated as of subordinate importance, the determination of species among these had scarcely been attempted, and thus the great principle now acted upon of determining the order of succession of the stratified deposits, not by the mineral composition of the rock, but by the species of the organic remains which it contains, was almost unknown; and the grand division of the stratified formations termed Tertiary, has been established by the discoveries of geologists since the period when Humboldt returned from South America. We have therefore to regret that many of the observations of that accomplished traveller are unavailable in the present more advanced state of geological science on account of their being described in the theoretical language of the Freyberg school, and having reference to doctrines of Werner, which later observations have proved to be untenable. When, in describing the unstratified rocks, he speaks of *old* and *new* granites, of primitive and transition syenites and porphyries, the terms are scarcely intelligible to a modern geologist, or at least convey to him no facts upon which general reasonings with regard to the rocks themselves, or the strata with which they are associated, can safely be founded. But the zoological characters of strata spread over so vast an extent of country could only be adequately described by the united labours, during a long period of observation, of many geologists, previously well instructed in all the knowledge of modern times respecting organic remains, and it is therefore no reproach to Baron Humboldt if he has left that field unexplored. Geology formed also but a part of the many objects which engaged his attention; and when we trace the line of his route, and compare his opportunities of personal observation with the extent of country which he never saw, we discover at once that all he could tell us is but a small portion of the geological phenomena of that vast region. If it has required years of the exertions of many labourers to arrive at our present knowledge of the geology of Europe; if a single volcano, like *Ætna*, has occupied the attention of naturalists for half a century, the observations of the latest inquirers bringing to light important facts unnoticed by their predecessors, what could be expected from the single visit of a single individual, however great his powers, to a whole continent of volcanoes, many of which greatly surpass *Ætna* itself in magnitude? Of this Humboldt was himself fully aware, for he says, (*Vues des Cordillères*, p. 4) ‘Ages would not suffice to observe the beauties and discover the wonders which nature has lavished over an extent of two thousand five hundred miles,* from the strait of Magellan to the coast bordering on eastern Asia. I shall believe that I have attained my object, if the feeble sketches contained in this work shall excite other travellers to visit the regions I have traversed.’ He is here speaking, it is true, of natural scenery, but we may reasonably suppose that he would say the same regarding all the other natural objects of his research. In everything which relates to the exact determination of the ages of the sedimentary deposits; the

* German miles.

changes of position which they have undergone; the organic remains which they contain; the alluvial accumulations of every period; the relative ages of the unstratified and volcanic rocks to each other, and to the strata with which they are associated, in short, with regard to almost all the most important phenomena upon which the general principles of the science of geology depend, the Andes, and, indeed, the whole continent of South America, may be considered as remaining still an unexplored field. We are far from undervaluing the labours of Humboldt; on the contrary, we have always looked with admiration and astonishment at what he accomplished, both by his own observation and by the skilful manner in which he has made use of materials obtained from others. But it is important for the cause of science that too ready an assent should not be given to the sweeping generalizations which have sometimes been attempted to be drawn from his observations; for a more deliberate investigation will show that all we learn from the perusal of his works, respecting the geology of South America, does not amount to much more than a knowledge of the existence of certain great classes of rocks, in the northern half of the continent, in so far as their mineral composition is concerned, and a broad outline of their relative positions; together with some interesting particulars concerning the great features of volcanic action on a stupendous scale. Humboldt, by those researches, must ever be considered as having made a most important contribution to geological science. From the materials scattered through his various works, and from a few hints supplied by others, we have been enabled to draw up the following brief sketch of the geology of the Andes, as well as most of that which we have said upon the general forms and bearing of the mountain-range. Such of our readers as wish to investigate the subject more fully than we are able to do in this place, consistently with the plan of the work, must go to the original sources, especially to the volumes of Humboldt, where they will find an abundance of matter the most varied, instructive, and entertaining.

The researches of Humboldt did not extend beyond the provinces of Upper Peru, so that our knowledge of the structure of the Andes of Chili and Patagonia is extremely scanty. Travellers speak of meeting in their routes across the mountains with granite and mica-slate, and clay-slate, porphyry, sandstone, and so forth; and the low countries between the shores of the Pacific and the base of the Andes is said to be composed of secondary rocks, including beds of coal. How little geological information such notices convey it is unnecessary for us to point out. Thus two thousand miles of this vast mountain-range, containing, no doubt, the most curious and important geological phenomena, may be said to be almost wholly unknown to us. *Tierra del Fuego*, or the ‘land of fire,’ may naturally be supposed to have taken its name from volcanoes having been seen on it; but, except that which Captain Hall saw at a distance in a state of activity, in 1822, no other is known. This volcano is placed near the Beagle Channel, (54° 48' S. lat., 68° W. long.) and still rests on the sole authority of Captain Hall. The range of the Andes, as we have remarked, if we consider the mountains of *Tierra del Fuego* to belong to them, must be looked for in the western part of the largest island forming the group of *Tierra del Fuego*, called *King Charles's South Land*, and in the adjoining westerly islands of *Clarence* and *Desolation*. *Magdalen Sound*, which divides *King Charles's Land* from *Clarence Island*, separates also the clay-slate from the more crystalline rocks of *Clarence Island*, which are greenstone; and on the east side of *Clarence Island*, mica-slate. The clay-slate contains *Mount Sarmiento*, already referred to, and east of it, *Mount Buckland*, which is described ‘as a pyramidal block of slate, with a sharp-pointed apex, and entirely covered with perpetual snow.’ Its height is stated at about 4000 feet. This slate formation, which occupies the centre of the strait, contains long valleys, often furnished with a rich mould, and producing trees of considerable dimensions. The region east of the clay slate, at least along the north shore of the strait, produces nothing but grass; and that west of it, only stunted trees. It is also remarkable, that the innumerable small islands which characterize the western parts of the strait are not found in the slate formation. This formation extends from *Cape Famine* in *Brunswick Peninsula*, across the strait, and along the *Gabriel Channel* and *Admiralty Sound*, in a direction E. S. E., and possibly continues to *Cape Success*, at the strait *Le Maire*. The east shore of *Tierra del Fuego* par-

takes of the character of the Patagonian Pampas. The south shores of Hoste and Navarin islands, which also belong to the Tierra del Fuego group, are hornblende, which is also the chief component part of Cape Horn.

Clarence Island is of a more rugged form than King Charles's Land, and tolerably verdant; in the Barbara channel, which separates it from Desolation Island, the fragments of rocks which compose the small islands are thickly strewn, and form the transition to the rough granitic mountains of the western part of Magalhaen's strait. The highest mountains, as we have observed, are in the slate formation, on the western side of King Charles's South Land. (See the articles STRAITS OF MAGALHAENS and TIERRA DEL FUEGO; and Captain King's *Charts*.)

Volcanos are said to exist in the Andes of Patagonia; and of these there are mentioned San Clemente in lat. 46°, Medialara in lat. 44° 30', and Minchimavidar in lat. 43°. The most remarkable feature in the physical constitution of the Andes of Chili is the great extent of volcanic action that has existed in past ages and is still in operation. No less than nineteen points of eruption, situated in a continuous line from south to north, that is, in the direction of the range, which have heaped up their ejected matter so as to form lofty mountains, have received distinct names, and there are probably many more of no inconsiderable importance which are still unknown. The most remarkable of the volcanoes of Chili are Villarica in lat. 39° 8', Maypu in lat. 34° 10', and Peteroa in lat. 35° 15'. Villarica is always in a state of activity, and may be seen, it is said, at a distance of 150 miles. Our more detailed geological description is, from want of materials, confined to the Andes of Peru and Colombia, and especially the latter.

The Stratified Rocks.

GNEISS is found at intervals throughout the greater part of the range, often associated with granite, and often passing into mica-slate. It frequently contains large quantities of garnet.

MICA-SLATE is, next to porphyry, the rock of most frequent occurrence in the Andes, and more especially north of the equator. In the Nevada de Quindiu of New Granada, it attains a thickness of more than 3800 feet; it contains, in some places, beds of granular limestone, occasionally resembling the finest Carrara marble; but limestone, subordinate to gneiss and mica-slate, is a much more rare occurrence than in the Alps and Pyrenees. Not far from Popayan, it contains beds of quartz and beds of gypsum, sulphur being found in the quartz, and in one place Humboldt observed a bed of lamellar graphite. It often passes by insensible gradations into clay-slate.

CLAY-SLATE occupies a space of small extent in the Andes. North of the equator, it is found immediately under secondary formations in the table-land of Santa Fe de Bogota, and south of the equator it serves as a basis to the porphyry in the Andes of Quito. It is found immediately beneath a secondary limestone at the height of 12,800 feet in the ridge of the Andes of Peru, and rests on granite on the western declivity of the same part of the range: but Humboldt is of opinion that the chief mass of the slate-rocks of South America belongs to the transition series of the Wernerian school, rather than to primary strata.

QUARTZ ROCK. South of Chimborazo, near Hecatacumba, in the Andes of Quito, there occur enormous masses of quartz rock mixed with mica. The primitive quartz observed in the mountains of Europe cannot be compared in thickness nor extent to that of South America: on the western declivity of the Andes of Peru, it attains the enormous thickness of 6000 feet, and there and elsewhere it covers many leagues. It contains gold, mercury, and specular iron in many places, and in the celebrated sulphur mountain of Tiscan, in latitude 2° 13' S., the sulphur is contained in a bed of quartz 1300 feet thick, subordinate to mica-slate, at an elevation of 8000 feet. Gold and sulphur are also found in a quartz rock in the Andes of Peru near Caxamarca, and the celebrated quicksilver mines of Guancavelica in Peru are also in the same rock.

RED SANDSTONE. A red sandstone occurs to a vast extent in the Andes of Peru, and over a great part of Colombia, not only in the Andes, but in the country east of that range, and to the shores of the Atlantic. It is often a coarse conglomerate, and passes through all gradations of structure to that of a fine-grained sandstone. From Humboldt's description of its occurrence at different places, it appears to belong to different ages, to the old red

sandstone, or newer beds of the grauwacke series, and to the lower beds of the new red sandstone, the *rothe todte liegende* of the Germans. A red sandstone covers an extent of country 25 leagues in length, forming the whole table-land of Tarqui and Cuenca in the Andes of Quito, at an elevation of from 8300 to 9600 feet, and it rises in the Paramo de Saar to the height of 12,150 feet, the thickness of the whole mass exceeding 5100 feet. The formation of red sandstone in the province of Quito is generally very argillaceous, sometimes slaty, and alternates with a conglomerate containing fragments of porphyry, and Humboldt found in it trunks of monocotyledonous trees four feet long and fourteen inches in diameter. It also contains there beds of an opaque limestone, and of a saccharoid limestone, like the marble of Carrara. In the llanos (plains) of Venezuela, these immense steppes, or mountain-plains, uniform like the surface of the sea over an area of 10,000 leagues, which stretch from the Sierra Nevada de Merida to the mouths of the Orinoco, are composed of a series of secondary rocks, the lowest of which is a red sandstone, or conglomerate of rounded fragments of quartz and flinty slate united by an argillaceous cement, sometimes of as vivid a red as cinnabar. This sandstone appears at the surface over the greater part of the llanos, but towards the east it is covered by beds of limestone and gypsum. In New Granada, the slaty fine-grained sandstone occurs to a greater extent than the coarse conglomerate. The latter disappears almost entirely when the formation rises to 5000 feet above the level of the sea; the sandstone of the table-land of Santa Fe de Bogota, at an elevation of 10,780 feet, is composed of small quartzose grains, sometimes so closely united as to give the rock the appearance of a granular quartz; it nowhere displays variegated colours, and animal remains are extremely rare in it. A similar red sandstone occurs in the great table-land of Caxamarca in Peru, at the height of 9350 feet. In the red sandstone of Santa Fe de Bogota, beds of coal are found, and in the great tract of red sandstone, between the lower part of the river Magdalena and Santa Fe, coal occurs in several places. Coal is also found at Huanuco in Peru, at an elevation of 14,750 feet,—the greatest elevation probably at which coal has yet been discovered. It occurs there in a compact limestone, but whether that is a subordinate formation in the red sandstone does not appear. Humboldt observed, between the seventh and eighth degrees of south latitude, a great formation, which he has called a secondary quartz rock, as it seems to replace the red sandstone on the western declivity of the Andes, and is covered immediately by magnesian limestone. It is a granular and compact quartz, stratified, without organic remains, and attains a thickness of several thousand feet.

The red sandstone of New Granada is covered by lamellar gypsum and by fetid limestone. In the basin of the Cauca and the plateau of Santa Fe, the former being 5750 feet lower than the other, the three formations of sandstone with coal, gypsum, and compact limestone succeed each other very regularly, and at Zipaquira, in the table-land of Santa Fe, rock-salt associated with this same gypsum and limestone has been worked for ages. The saliferous deposit is not less than 830 feet thick, and is covered by great masses of granular gypsum, the red sandstone appearing beneath the saliferous clay. Deposits of rock-salt and brine-springs are of frequent occurrence in traversing the eastern cordillera of New Granada from S.W. to N.E. for a distance of more than 50 leagues. Rock-salt is also found in the Peruvian provinces of Chachapoyas, on the eastern declivity of the Andes, and, what is remarkable, contains there masses of galena or sulphuret of lead. At Huara, on the coast of Peru, between Lima and Santa, rock-salt is worked like marble in a quarry, and at the same place rocks of porphyry pierce through beds of the purest rock-salt. The red sandstone of the llanos of Venezuela is covered by a whitish-grey compact limestone, and above the limestone there occurs gypsum alternating with beds of marl. This limestone, according to Humboldt, is an equivalent of the zechstein of the Germans, the magnesian limestone of English geologists. It is met with in various parts of the Andes of Peru, at elevations from 9000 to 14,000 feet, and it contains beds of bituminous marl slate, with impressions of fish, (as at Mansfeld, in Germany,) near Pasco, in the Andes of Peru, at the height of 12,800 feet. In the mine Santa Barbara, near Guancavelica, an immense bed of sandstone, containing a deposit of mercury, is met with in this same limestone.

It does not appear, from the observations of Humboldt,

that any of the secondary strata later than the magnesian limestone occur in any part of the Andes, or the adjoining country, which was visited by him, and he expressly says that he never met with either *oolite* or *chalk*. The only tertiary formation he speaks of is one in the table-land of Santa Fe de Bogota, which appears to have been a lacustrine deposit, and in which he found enormous bones of the extinct species called the *mastodon*. That the whole series of the secondary strata above the magnesian limestone should be wanting, and that there should be a total absence of all tertiary marine beds in one-half of the continent of South America is very extraordinary, and scarcely probable. But notwithstanding this imperfect state of our knowledge respecting that vast country, an eminent French geologist, M. Elie de Beaumont, in his eagerness to generalize a favourite theory,—a theory intended to show a connexion between the elevation of mountain-chains and the extinction of species of organic remains in the successive sedimentary deposits,—has, of late, not hesitated to declare his belief, that the whole line of the Andes must have been upheaved by a single and instantaneous convulsion; that that convulsion was the last which has taken place in the solid covering of the earth, and that, by the agitation which it produced in the ocean, it was the immediate cause of the general deluge. So great a departure from the rules by which philosophical inquiries ought to be guided is a remarkable proof how dangerous, in a progressive science, an attachment to a particular theory may prove,—how very readily arguments with a mere semblance of plausibility will be admitted, even by a man who has worked assiduously in the field of observation, and knows full well how extensive and accurate our observations must be, before any general conclusions can safely be deduced from them.

The Unstratified Rocks.

The most elevated summits of the Andes—the composition of which is known—are either volcanic, or are composed of porphyry. Granite, which, in the old continent, rises to elevations of 15,000 feet, is never found at great heights in the Andes, and, indeed, forms but a small part of their external surface. Humboldt says, that one might pass years in travelling through the Andes of Quito and Peru, almost without seeing it, and he never met with it at a greater elevation than 11,500 feet. It is seen at the foot of the range in the plains of the Orinoco and Amazon, and on the shore of the Pacific between Lima and Truxillo. But Humboldt distinguishes three different kinds of granite, one which he calls primitive, and considers as the foundation upon which all other rocks were deposited, in accordance with the Wernerian hypothesis; another, which he makes of posterior formation to gneiss, but anterior to mica-slate; and a third, older than clay-slate, but of a formation subsequent to that of mica-slate. Modern discoveries have shown that granites, undistinguishable from one another in their mineralogical characters, are associated with some of the most modern of the secondary strata; and these distinctions of Humboldt are founded upon erroneous theoretical views, because the granite that lies under the gneiss may have been protruded to the surface later than that which is associated with the mica-slate. The same observations apply to his old and new *yenites*,—a variety of granite containing a mixture of hornblende, which is found in several parts of the Andes of Peru and Colombia. Porphyry is, by far, the most widely-extended of all the unstratified rocks of the Andes, and Humboldt distinguishes two kinds,—one which, he says, reposes immediately upon primitive rocks, and is not metalliferous; and another, which is often rich in metals and appears to belong to the transition period. The primitive porphyry is of rare occurrence; it is found on the western declivity of the Andes of Peru, at an elevation of about 8800 feet, and rests immediately upon granite. In the Andes of Peru, Quito, and New Granada, among an innumerable variety of porphyritic rocks, the masses of which are from 16,000 to 19,000 feet in thickness, there is not one which Humboldt considers as belonging to the primitive porphyries. They often exhibit superb columns, as at Pisaje, at the western declivity of the volcano of Purace, where there is a magnificent colonnade, the pillars of which are eighteen feet long, and formed of regular prisms of five, six, and seven sides. They have also very often a globular structure, as if the mass were composed of an aggregation of balls, which separate by decomposition into concentric layers. This globular structure is extremely common in the unstratified rocks of the Andes. To describe the various

kinds of porphyries, or even their chief localities, would be both tedious and unprofitable; it is enough to say, that they occur throughout the whole range of the Andes, at all elevations, and that the highest summits are frequently composed of them.

Next in importance to porphyry among the rocks of igneous origin is that called *TRACHYTE*, (from *τράχης*, *trachus*,) rough, because it has a harsh, rough feel. There are many varieties of it, but its most characteristic form is a hard rock with a granular basis of glassy felspar, and including separate crystals of glassy felspar usually with a mixture of hornblende, and often mica; and these materials are united in so many different proportions as to produce rocks of very different aspects. Trachytes occur throughout the whole range of the Andes of Chili, Peru, and Colombia; the porphyries are often covered by them, and it is not easy to define the limits between trachytes which pass into porphyry and those which are produced by active volcanoes. Like porphyry and basalt, trachyte is often found in columns of great regularity, as in Chimborazo, where it is met with in slender prisms of 50 feet long. It occurs in enormous masses, for Humboldt says that in Chimborazo and Pichincha it undoubtedly attains a thickness of from 14,000 to 18,000 feet, and in continuous masses. The trachytes are most frequently not covered by any other formations except recent volcanic products, and this is also, in general, the case with the porphyries; but these are sometimes covered by the older sedimentary deposits, showing that there are porphyries of very different ages in the Andes; and there is every reason to suppose that trachytes have also been formed at various periods.

The Andes are often throughout a great extent wholly destitute of the trap-rocks: neither in Chimborazo, Antisana, nor Pichincha are there any rocks of this class; but basalt characterised by olivine, and regularly columnar, is found in the table-land of Quito, near Popayan, and on the western banks of the Cauca. The basalt, or trap-formation, in the vicinity of Popayan, as well as in other situations in the Andes, is accompanied by clay of great thickness, which renders the passage of the cordilleras from Popayan to Quito extremely difficult during the rainy season.

Volcanos.

No part of the world has been subjected to greater revolutions from volcanic fires than the range of the Andes. The igneous action has been confined to this western side of the continent, for, east of the Andes, throughout the whole country from the base of the mountain-range to the Atlantic, a space of more than 500,000 square leagues, neither porphyry, basalt, trachyte, nor any active volcanoes have yet been discovered, either in the plains, or in the mountains of Guiana and Brazil. In the range of the Andes, where their products do not cover the whole surface, they are found in insulated masses on the ridges and on the sides of the mountains rising in the form of pyramids, or of cones, amidst the stratified rocks of different ages. All the volcanoes, whether extinct or active, have burst forth amidst porphyries, basalts, and trachytes; all the loftiest summits of the range are composed of trachyte, and the opening is usually in the latter rock. It may be considered as a general rule, that when the mountains rise much above the limit of perpetual snow, that is, from 14,700 to 15,800 feet in the equatorial regions, the rocks commonly called primitive, such as granite, gneiss, and mica-slate, disappear, and are replaced by porphyries and trachytes. That these last substances are often granite, gneiss, and slates, altered by the action of heat, is rendered probable by many circumstances connected with them, and the trachytes of the Andes frequently include fragments of those primary rocks. It is very difficult to draw the line of separation between the various kinds of unstratified rocks, all of which are now admitted by most geologists to be of igneous origin. Granites and porphyries change into trape and trachytes; these last into the lavas of active volcanoes; and thus any conclusions as to the ages of the unstratified rocks, drawn from mere mineralogical differences, are open to many sources of error. The glassy lava, called *obsidian*, is often met with in the Andes, and exhibits many shades of colour, from deep black to a clear, colourless glass. Beds of it, 16 inches thick, occur in the trachyte of Quinché, in the table-land of Quito. Fragments of rock, including nodules or lumps of obsidian are thrown out by Cotopaxi, and obsidian in the form of balls, and in those elongated pear-shaped forms called *tears*, is ejected by the volcano of Sotara near

Popayan, to the distance of several leagues, and scattered about like fragments of flint on the chalk-downs. Pumice-stone, which is nothing more than obsidian frothed up by the admission of air or watery vapour to it when it was in a fluid-state, is found to a great extent in many of the volcanos of the Andes; there are immense subterranean quarries of it at the foot of Cotopaxi, and for more than 40 leagues westward of the volcano, the ground is covered with fragments of pumice and cinders of trachytes. Volcanic-tuff, which is a stone more or less compact, made up of fragments of hard lava, cinders, and ashes, agglutinated together, covers immense tracks on the flanks of the Andes and on the table-lands. It is often very friable, and in many places contains blocks of pumice, which are sometimes from 25 to 30 feet long. In a region where almost all the burning volcanos rise above the limit of perpetual snow, deluges of water are often produced by the melting of the snow, and by the bursting of cavities in which water had accumulated by infiltration, and these carry along with them the loose stones, and give rise in lower regions to depositions of this tuff, of a magnitude in proportion to the volume of water and the loose materials it meets with in its descent. A liquid mud sometimes issues from the sides of the volcanos of the Andes, as when, in 1698, the peak of Carguairazo sunk down, and more than four square leagues were covered with mud; and, what is very remarkable, small fish which inhabit the streams of the province of Quito were seen in thousands, enveloped in the muddy eruption. These fish live in subterranean lakes; at the time of great eruptions the sides of these lakes are burst, the fish are carried with the water through the crevices and are enveloped in the mud formed as the water rushes through the loose ashes and soil. The almost extinguished volcano of Imbaburu ejected in 1691 so great a quantity of fish, that fevers which prevailed at the period were attributed to the effluvia from the putrid animal matter.

The most considerable volcanos of the Andes are situated not far from each other in the province of Quito. These are, Cayambe, Cotopaxi, Pichincha, Antisana, L'Altar, and Tunguragua. Of all the summits of the Andes the height of which has been determined with any degree of precision, the volcano of Cayambe is the most lofty after Chimborazo—being 19,625 feet. Its form, like the volcano called the Nevada de Tolima, is that of a truncated cone, and it is one of the most beautiful and majestic of all those which surround the city of Quito. Its summit is crossed by the line of the equator, and it stands, says Humboldt, like one of the colossal and eternal monuments placed by the hand of nature to mark the grand divisions of the globe. According to a very probable tradition of the Indians of Lican, the mountain called L'Altar, or in the Quichoa tongue, Capa-Urcu, was once higher than Chimborazo, but in the reign of Ouainia Abomatha a prodigious eruption took place, which lasted eight years, and broke it down. The summit of this remarkable mountain presents a series of sharp pinnacles and needles, and when the rays of the setting sun strike upon these ice-clad ruins, the most magnificent play of colours is produced. The volcano of Antisana, which is 19,120 feet high, appears never to have had its summit pierced, the lava having burst forth from an opening in the side. Pichincha, which is 15,920 feet high, has a crater, the edges of which are covered with pumice, but it does not appear to have ejected a current of lava since the formation of the adjoining vallies. The volcano of Cotopaxi is the most lofty of all the volcanos of the Andes which have been in a state of activity in modern times. Its height is such (18,858 feet) that it would exceed by 2600 feet the summit of Vesuvius if that volcano were placed on the top of the peak of Teneriffe. It is the most dreaded of all the volcanos of Quito, because its eruptions have been the most frequent and the most devastating in their effects. In 1738 the flames rose nearly three thousand feet above the edge of the crater. In 1744 the sound of the explosions was so great as to be heard at a distance of five hundred and fifty miles. On the 4th of April, 1768, the quantity of ashes thrown out was so great that in the towns of Hambato and Tacunga such a degree of darkness was produced as to oblige the inhabitants to go about with lanterns for many hours in the day-time. The eruption of January, 1803, was preceded by sudden melting of the snow which covers the mountain. For twenty years no smoke nor visible vapour had issued from the crater, but in a single night the internal fires became so active, that at sunrise the external walls of the cone were observed to be black and bare, their mantle of snow having been dissolved by the

heat. The form of Cotopaxi is the most regular and beautiful of all the colossal summits of the Andes. It is a perfect cone, which, covered with an enormous bed of snow, shines with a dazzling lustre at sunset, against the azure vault of heaven. The crater is surrounded with a wall of scoræ, but it was only seen by Humboldt by means of a telescope, for the cone being surrounded with deep rents and fissures, cannot be approached.

A region so underlaid by volcanic fires could not fail to be subject to repeated earthquakes, and accordingly, no part of the world has suffered more from their dreadful effects. Sometimes the shocks come without giving any warning at all, and ruin and devastation are spread over a district which, an instant before, had been in a state of peaceful repose; in general, however, the inhabitants are forewarned of the approach of the convulsion, but the interval between the announcement and the arrival of the destroying force is too short to admit of any precautions against the loss of property; it is well if there be time enough to escape from death. Such is the frequency of the occurrence, that the inhabitants construct their dwellings so as to diminish the risk of damage to the building, and to facilitate their own escape. But no precautions can give confidence in such a case, and the terror which takes possession of the people extends to the brute creation, for the animals howl piteously when they feel the ground rocking under them. The effects are often produced far from the supposed centre of the volcanic action, for even the towns on the sea-shore are often destroyed. The whole of Chili is particularly subject to earthquakes. The city of Copiapo was entirely destroyed in the year 1819, not a house being left standing; and the city of Concepcion has been twice destroyed, viz., in 1730 and 1751. An earthquake of tremendous force occurred on the 19th of November, 1822, which shook not only the whole of the low country of Chili, but was felt in the mountains, and even at Mendoza and San Luis, on the eastern side of the chain. The towns of Valparaiso, Mellipilla, Quillota, and Casa Blanca, were almost destroyed, and the capital, Santiago, was considerably damaged. It was felt on the same day at Lima, in latitude 12°, and at Concepcion, in latitude 37°, a distance of more than 1700 miles. One of the most remarkable effects of this earthquake was the elevation of the land on the coast; above a hundred miles of it was permanently upraised to the height of three or four feet, a portion of the bed of the sea being converted into dry land, covered with oysters, mussels, and other shell-fish. A circumstantial account of the phenomena which occurred near Valparaiso, by Mrs. Graham, who was then living in the country, will be found in her *Journal of a Residence in Chili*, and in the first volume of the *Second Series of the Transactions of the Geological Society*. The volcano of Maypu, situated about 170 miles E.S.E. of Valparaiso, which had been dormant for several years, has had frequent eruptions since the great earthquakes of 1822, for it was not one shock only which took place; many succeeded at very short intervals, even to the end of the following September.

Mines.—No mountains in any part of the globe abound so much in the precious metals as the Andes, both in South America and in the prolongation of the chain northward into Mexico. For three centuries their riches have been spread over every part of the globe to which civilization has extended, and it is probable, that if improved systems of working the mines were introduced, where there are no natural obstacles to their adoption, the produce would be immensely increased.

GOLD is seldom found, like other metals, in the solid rock, through which its veins must be followed by extensive subterranean excavations, nor is it met with in ores, in combination with foreign substances, which can only be separated from the pure metal by long and expensive operations. It is always found in the metallic state, and in a great degree of purity; by far the largest quantity is collected in the form of grains and small rounded lumps, scattered through alluvial soils, which have been derived from the disintegration of rocks containing the metal, and most probably in the form of slender veins. The water-courses of rivers are usually composed of alluvial soil to a great depth, and that soil frequently extends a great way on both sides of the river, the deposits of a long succession of ages; the grains of gold are disseminated through the whole of this alluvium. The places chosen for digging into that auriferous soil are called *lavaderos*, because the grave

sand, and earth undergo repeated *washings* to separate the heavy particles of gold. The most considerable gold mines of Chili are in the district of Petorea, N.E. of Valparaiso, and farther to the north in the districts of Coquimbo and Copiapo. In Peru, the provinces the most rich in gold are those of Pataz and Huailas, between the seventh and ninth degrees of latitude, and situated in the ridge of the Andes. The Incas obtained vast quantities of gold from the plains of Curimayo, N.E. of the city of Caxamarca, at an elevation of more than 11,000 feet above the sea; and in the Cerro de San José, at a height of 13,000 feet, considerable quantities of gold have been found in veins of an ore of silver. Very extensive and productive *lavaderos* are situated on the banks of the river Tipuani, not far from the town of Zorata, eastward of the great lake of Titicaca, and which appear to have been worked by the early inhabitants of the country, for ancient Peruvian tools are sometimes found in the soil. There are veins of gold in mica-slate in the province of Antioquia in Colombia, but there are no mines worked there, on account of the inaccessible nature of the country. All the gold of New Granada is obtained from the alluvial soils, and the richest *lavaderos* are in the provinces of Antioquia and Choco, in the valley of the river Cauca, and on the coasts of the Pacific in the district of Barbacoas; but the auriferous alluvium extends over the whole country from the western Cordillera of New Granada to the sea-shore. In some parts of the district the gold is almost perfectly pure, in others it is alloyed with silver in various proportions, even as much as 50 per cent., but this last has been found only in one place. The largest piece of gold known to have been met with in the province of Choco weighed twenty-five pounds; but one is said to have been found near La Paz, in Peru, of nearly forty-five pounds weight. The annual produce of the gold mines and *lavaderos* of Chili, Buenos Ayres, Peru, and New Granada is stated by Humboldt to have amounted at the beginning of the nineteenth century to 8809 kilogrammes, or 283,429 troy ounces, equal, at 4*l.* per ounce, to the sum of 1,133,716*l.* sterling.

SILVER is found in Chili, but the mines are in general not productive, except in the Cerro de Usallata, twenty-four miles N.W. of the city of Mendoza, on the eastern side of the Andes, where an ore is worked which yields about fifty marcs of silver in every hundred pounds of ore. In Peru there are silver mines along the whole range of the Andes from Caxamarca to the confines of the desert of Atacama; but the richest are those of Pasco, in the eleventh degree of latitude, which have been worked since the year 1630. Here, as well as in other situations in Peru, the greatest part of the silver is obtained from an ore called in the country *pacos*, which, according to the analysis of Klaproth, is an intimate mixture of minute particles of native silver with brown oxide of iron. To form a just idea of the enormous quantity of silver in some of these mountains, it is only necessary to state, that in the mines of Pasco the ore has been worked without intermission since the beginning of the seventeenth century, and that in twenty years preceding 1803 no less than 5,000,000 marcs of silver had been obtained from them, and that too without in any case sinking deeper than about seventy fathoms, while most of the mines do not exceed fifteen fathoms in depth. The stratum of limestone in which the ore is contained lies exposed at the surface over an area of three miles by a mile and a half. The mines of Chota are also very productive. They are situated in the mountain of Gualgayoc, at an elevation of 13,300 feet, where the thermometer in summer descends every night to the freezing point. The ore lies quite at the surface, so that in removing the turf almost in any place, over an extent of half a square league, portions of sulphuret of silver and filaments of native silver may be met with adhering to the roots of the grass. The ore is richer than that of Pasco, and yielded on an average of twenty-eight years prior to 1803, 67,193 marcs of silver annually. In the district of Arica, on the very borders of the Pacific, at Huantajaya,

there are mines of silver which are celebrated on account of the very large masses of pure solid silver sometimes found there, one of which weighed eight hundred pounds. The most renowned of all the silver mines of South America are those of Potosi in Upper Peru. They are situated in a lofty mountain called the Cerro del Potosi, composed of clay-slate covered by porphyry, and rising to the height of 16,000 feet above the sea, the town of Potosi itself being 2700 feet below the summit. The mountain is perforated in all directions, and it is said that there are not less than five thousand excavations in it, some of them within 120 feet of the top; indeed the works have hitherto been almost confined to the higher parts of the mountain for the sake of more easily getting rid of the water, but an adit or drain more than a mile and a quarter long and fourteen feet square, has been constructed in order to carry off the water from the lower mines. There are rich veins of silver in several parts of New Granada, but no mines have yet been found sufficiently productive to pay the expense of working them. The annual produce of silver from the mines of Chili, Peru, Buenos Ayres, and New Granada, is stated by Humboldt to have been at the commencement of the present century, 258,069 kilogrammes, which is equal to 691,492 lbs. troy, and if we take the silver at only five shillings the ounce, it gives a sum of 2,074,476*l.* sterling. The produce of the mines of Potosi are included in the returns from Buenos Ayres.

MERCURY, or QUICKSILVER, is found in many parts of the Andes, not in a pure and fluid state, but in combination with sulphur, forming that particular red ore of mercury called cinnabar. Near the village of Azogué, (the name of which means quicksilver,) north-west of Cuenca, the ore is found in a quartzose sandstone, 4600 feet thick, containing fossil wood, and asphaltum or mineral pitch. It is found in many parts of Peru, but the most celebrated quicksilver mines of South America were those situated in the mountain Santa Barbara, near the town of Guancavelica, until they were accidentally destroyed. The mountain is 12,300 feet above the level of the sea: the cinnabar occurs in the form of layers and of veins in a sandstone, almost as compact as pure quartz, thirteen feet thick, forming a subordinate bed in a calcareous breccia, that is, a rock composed of fragments of limestone cemented together, resting upon, or rather being a part of the extensive formation of magnesian limestone, which, in this place, abounds in pectens and cardiums. These mines were worked by the Spaniards as far back as the year 1570, and from documents which have been regularly kept, it appears that they had in general yielded annually from 400,000 to 600,000 lbs. of quicksilver, and in some years as much as 1,050,000 lbs. But in 1789, an ignorant superintendant, wishing to increase the produce, caused the miners to work the masses which had been left to support the roof, as is usually done in coal-mines; the consequence of this was, that when these pillars were taken away the roof sunk down to the floor of the mine, and closed it.

PLATINA is met with only in the provinces of Choco and Barbacoas, in the north-western part of Colombia, west of the sandstone mountains on the left bank of the Cauca, in the same alluvium from which the chief part of the gold of New Granada is obtained, but only in the form of grains, for it has not been found united with any matrix. The grains are usually small, lumps being very rare; the largest of those hitherto found, which is in the Royal Museum at Madrid, weighs no more than twenty-one ounces.

COPPER is found in Peru, and is by far the most valuable of all the metallic productions of Chili. The mines are chiefly in the northern provinces of Coquimbo and Copiapo, but there are also some of great value in the southern provinces, or rather in what is usually termed the country of the Araucanos. The average annual produce of Chili in copper is estimated at 14,000,000 lbs., and it is exported to the United States, China, the East Indies, and many parts of Europe.

TIN is also found in Chili, and forms an article of export.

A N D

ANDO'CIDES, the son of Leogoras, of a noble Athenian family, was born about B.C. 468. We find him, during the war of the Corcyraeans and Corinthians, commanding, jointly with Glaucon, an Athenian squadron which was sent to aid the Corcyraeans (Thucyd. i. 51). After this he appears to have been employed as ambassador on numerous foreign missions. During the Peloponnesian war (about B.C. 415) Andocides was involved in the charge of mutilating the Hermae, (see **ALCIBIADES**.) and, according to Plutarch, he saved himself by accusing his real or imaginary accomplices, and among them his own father, whom however he succeeded in rescuing from capital punishment. But the history of all this transaction is obscure. After this event Andocides went abroad and visited Sicily, Italy, the Peloponnesus, and Thessaly: he also visited Asia Minor and the island of Cyprus, where he became on good terms with the king of Citium, to whom he is accused of delivering up his own cousin, a female, whom he had carried off from Athens. The story rests on doubtful authority; but the king and the Athenian adventurer appear to have quarrelled, and Andocides made his way back to Athens. The Four Hundred at this time (B.C. 411) directed the administration of affairs, and Andocides, who was always in trouble, was accused apparently on frivolous grounds, and thrown into prison. On being released he set out again to Cyprus, and attached himself to Evagoras, king of Salamis. But he quarrelled with this new acquaintance also, and again returning to Athens after the restoration of the popular government, he was once more compelled to quit the place and to retire to Elis. On the overthrow of the Thirty Tyrants by Thrasybulus, (B.C. 403,) Andocides returned to Athens, and recovered all the influence which talents and eloquence naturally gave an unprincipled man in the Athenian democracy. The remainder of his life is obscure. The life of Andocides, attributed to Plutarch, speaks of his being sent to Lacedæmon on the subject of the peace (*τῆς εἰρήνης*), in which affair he conducted himself in such a way as not to venture back to Athens. This peace has been conjectured to be that of Antalcidas, B.C. 387, but at this time Andocides was eighty-one years of age, if the date of his birth is correctly given, and not likely to have been employed on such a mission.

It is unfortunate that the events of this orator's rambling life are not better known. The times during which he lived were full of important occurrences, and a minute account of his life and adventures would have thrown great light on the internal history of Athens and that of other states also. There is little doubt that he was a man of ability, but without any principle.

Four extant orations are attributed to Andocides: *On the Mysteries*; *On his (second) Return to Athens*; *On the Peace with the Lacedæmonians*; and that *Against Alcibiades*. The authenticity of the third and fourth are disputed, that of the third at least, perhaps, with good reason.

The orations of Andocides are found in the collections of the Athenian orators, by H. Stephens (1575), in that by Reiske, and in the later edition of Bekker. They are also in Dobson's collection (1828), with the *Lectiones Andocidææ* of Sluiter, &c. They were translated into French by the

Abbé Auger, 1792. The oration on the Mysteries was pronounced when Andocides was about seventy years of age, in reply to an accusation brought against him by Callias of violating a law respecting the temple of Ceres at Eleusis. The oration contains, besides the immediate subject of the defence, much information on other parts of the orator's life. It is an admirable specimen of simple and perspicuous language, and equally remarkable for the skill with which the defence is conducted.

ANDORRA, a valley on the southern side of the central Pyrenees, situated between two of the highest mountains, the Maladeta and the Moncal, the former 3808 and the latter 3570 yards above the sea. The extent of this valley is forty miles in length, and twenty-four in breadth; it is bounded on the east and south by the territory of Puigcerdà, by Talarn on the west, and on the north by the Pyrenees and the county of Foix, in France. The rivers Balira, Odino, and Os irrigate its grounds, and flow into the main stream, the Segre, which is a branch of the Ebro. The territory is mountainous, but abundant in pasturage. At Caldes, as its name imports, are abundant thermal springs. Its forests produce a great quantity of timber, which is carried down the rivers Balira and Segre into the Ebro, and thence to Tortosa. The mountains abound in bears, wolves, wild boars, goats, and other species of game. Besides Andorra it contains five other villages; Encampo, Masano, Ordino, San Julian, and Camillo, the latter remarkable for its iron mines. The capital, Andorra, is situated on the river Balira, and contains 2000 inhabitants.

Andorra is an independent republic, and though double in extent, is less known than that of San Marino, in Italy. It is governed by a syndic, who presides in the council of the valley, and by two *Viguiera*, one appointed by the king of France and the other by the bishop of Urgel. Lewis le Debonnaire gave the sovereignty of this valley to Sisbertus, the first bishop of Urgel, in 819, and from that time it has maintained its independence between France and Spain. Andorra, the chief town, on the Balira, has about 2000 inhabitants. The people of the territory speak a Catalan dialect.

See Miñano; Malte Brun, *Universal Geography*, vol. viii. p. 124. Balbi, *Abrégé de Géographie*, p. 370.

ANDOVER, a borough and parish in the N.W. part of the county of Hants, and on the border of the downs which stretch into Wiltshire. It is on the left bank of the river Anton, (a branch of the Tese, or Test, which falls into Southampton water,) and from its situation, gets the name of Andover, (Saxon, Andeafaran,) i. e., ferry, or passage over the river Ande. It is 63 or 64 miles W.S.W. from London; 51° 12' 30" N. lat., 1° 28' W. long. from Greenwich.

The three principal streets are well paved, but not lighted; the houses are well built, and the town is well supplied with water. The church is near the north end of it, and is a spacious structure, of very great antiquity, having existed as far back as the time of the Conqueror. At the west end is a fine semicircular, arched doorway, with zigzag mouldings. The living, a vicarage, with the chapelry of Foxcote annexed, is in the patronage of Winchester College. There

are meeting-houses for Baptists, Quakers, Independents, and Methodists; a free grammar school, with a school-house built and kept in repair by the corporation; and an almshouse for six poor men, erected and endowed by John Pollen, Esq., one of the members for the borough in the time of William III. Another almshouse, for six poor women, was built with funds bequeathed by Catherine Hanson, but not endowed. There is also a school-house erected and endowed by John Pollen, Esq., for educating twenty poor children. This establishment is now incorporated with the National School, supported by additional subscriptions, in which 250 children are educated.

The town-hall is a handsome stone building with a Grecian front, supported by arches; the under part is used as a market-house. It was erected within these few years. The corporation is said to be as ancient as the time of John; but the present charter was granted by Queen Elizabeth.

Andover first returned members to Parliament in the time of Edward I.; but the right was lost, or disused, from the first year of Edward II., to the twenty-seventh year of Queen Elizabeth, when they were again sent, and have since been regularly returned. Before the passing of the Reform Bill, the right of election was in the corporation, which was considered to be under the influence of the Earl of Portsmouth. By the Boundary Act connected with the Reform Bill, the tything of Foxcote was added to the Borough, which had previously included the parishes of Andover and Knight's Enham. The population of the whole was, in 1831, 4966.

The chief business of the town consists in malting, and in the manufacture of silk, which has lately superseded that of shalloon, the former staple. A considerable quantity of timber is forwarded from Harewood forest to Portsmouth, by means of the canal from this town, through Stockbridge, to Southampton water. The market is on Saturday; and there are three fairs in the year.

About three miles west of the town, at the village of Weyhill, is held one of the largest fairs in England. This fair begins on the 10th of October, and continues for six days. It is thus described in '*Magna Britannia Hibernia*,' a survey of Great Britain, published in 1720. 'This fair is reckoned to be as great an one as any in England, for many commodities, and for sheep, indisputably the biggest, the farmers coming out of the south, north, and east to buy the Dorsetshire ewes here. It is also a great hop and cheese fair, the former being brought out of Sussex and Kent, and the latter out of Wiltshire, Gloucestershire, and Somersetshire.' The above account of the chief articles of trade, will apply with little alteration to the present day. The sale of sheep, though the favourite breed may be different, is still great: more than 140,000 have been sold on the first day. The Farnham hops, the choicest of any grown in England, are chiefly sold here, and a place appropriated to their sale, bears the name of Farnham Row. Many horses, particularly cart colts, are also sold.

During this fair, assemblies are held in the town-hall at Andover.

Near Andover, there are the remains of some Roman encampments, especially one on the summit of Bury Hill, a mile or two south-west of the town; and some beautiful specimens of Roman pavement have been found in the neighbourhood. (Warner's *Hampshire*; *Beauties of England and Wales*.)

ANDOVER, a town in the state of Massachusetts, United States, about twenty miles direct distance N. by W. of Boston, and about two miles from the southern bank of the Merrimack river. It is also watered by the Shawshoen. Andover is divided into three parishes, and has some inconsiderable manufactures. The north parish contains the Franklin Academy, and the south parish the Theological Seminary, and Phillips's Academy. The Theological Seminary opened in 1808; it has four professors and (in 1831) 139 students, with a library of 10,000 volumes. The whole number that has been educated here was (in 1831) 514. This establishment has acquired some celebrity from the impulse it has given to the study of Hebrew in the United States. The population of Andover in 1820, was 3889. (*Encyclop. American.*; *Journal of Education*, Nos. x., xi.)

ANDRE' (ST), or ST. ENDRE', the capital of a lordship in Hungary, in the circle called the Hither Danube, and in the department of Pesth; the number of its inhabitants scarcely exceeds 3000. Their chief support is

derived from the cultivation of the vine. The eastern Christians, who are in number about 1000, have seven churches in the town; which gives an average of scarcely more than 157 persons to each church. This singular circumstance originated in the immigration of the Servians under Leopold I., each sect of whom founded their own place of worship.

ANDRE' (JOHN), appears to have been a native of Lichfield, and to have been born there in 1751. In 1769 he met at Buxton a Miss Honoria S——, and the consequence was an immediate attachment, which became one of remarkable devotedness on his part, and which would seem to have been also returned by the lady. Her friends, however, interfered, and she was induced not only to discontinue her correspondence with André, but some years after to give her hand to another. Meanwhile André had become a clerk in a commercial house in London. But on receiving intelligence of Miss S.'s marriage he determined to quit both his profession and his country, and having procured a commission in the army, he proceeded with his regiment to North America, then the seat of war between Great Britain and her colonies. In this new field of enterprise his talents and accomplishments soon raised him to distinction; and he attained the rank of major, with the appointment of adjutant-general to the North American army. In the summer of 1780 Major André was with the troops which occupied the town of New York under the command of General Sir Henry Clinton, when the infamous Arnold, who had been entrusted by Washington with the important position of West Point on the Hudson, about 60 miles above New York, sent over to the British commander his proposals for delivering that fortress into his hands—a scheme which, if it had succeeded, might not improbably have put an end to the war. On Arnold's overtures being accepted, André was appointed to conduct the negotiation with him. After some correspondence under feigned names, André and Arnold met on the banks of the Hudson on Friday the 22d of September, when everything was arranged for the execution of the plot on the following Monday, and the necessary information in writing was put into André's hands to be delivered to General Clinton. Unfortunately for André, the boatmen who had brought him on shore from the English sloop of war in which he had come up the river, having had their suspicions or fears awakened, refused, although he bore a flag of truce from General Arnold, to convey him back, and he was obliged to determine upon attempting to make his way to New York by land. Arnold, to whom he returned, insisted, in these circumstances, that he should exchange his military uniform for a plain coat; and to this André reluctantly consented. A person of the name of Smith was then sent away with him as his guide, and they set out together; but when they reached the next post, they found themselves obliged, in order to prevent suspicion, to follow the advice of the commanding officer, and to remain there for the night. Next morning they proceeded on their journey, and Smith having conducted his charge till they had come within view of the English lines, left him a little below Pine's Bridge, a village on the Croton. André rode on alone for about four leagues farther, when as he was entering the village of Jarrytown, his horse was suddenly taken hold of by three men, who turned out to belong to the New York militia. With unaccountable imprudence, André assumed that they were of the English party, and instead of producing his passport desired them not to detain him, as he was a British officer. When he found his mistake, he endeavoured to induce them to let him go by the offer of his watch and the most tempting promises; but the men were not to be bribed, and having found the important papers of which he was the bearer concealed in his boots, they immediately conducted him to the nearest station. His first anxiety now was for the safety of Arnold; and he contrived to prevail upon the officer in command, who must have been a person of very little perspicacity, to forward a notice of his capture to that general, by which the traitor obtained the opportunity of escaping with his life. Having secured this point André now stated who he was, on which he was conducted to the presence of General Washington at Tappan or Orange Town. On the 25th, his case was submitted by the American general to the consideration of a board of fourteen general officers, among whom were Rochambeau and Lafayette, who had recently arrived with the troops from France. Before this tribunal, André urged that he had come on shore under the sanction of a passport, or flag of truce, transmitted to him by Arnold.

who was, at the time of granting it, a major-general in the American army, and of course had sufficient authority so to act. But the circumstance of his having been found disguised and bearing a false name was considered as taking from him the benefit of this plea, although he proved that in both these points he had acted in obedience to the commands of Arnold, under whose orders he was while he bore his flag of truce. The decision of the court-martial, though the members do not appear to have been unanimous, as has sometimes been asserted, was that the prisoner ought to be considered as a spy; and he was accordingly sentenced to be executed. Both entreaties and remonstrances were employed in vain by General Clinton to avert his fate; but as retaliation was not taken by the execution of any American prisoner, it may be inferred that it was felt even by the English that his sentence was according to the rules of martial-law. He himself exhibited the most perfect resignation to his fate, and does not after his condemnation appear to have disputed the justice of the decision under which he was to suffer. He only begged that his death might be that of a soldier. He was kept in ignorance of the determination of the court-martial upon this point; but when upon being brought to the fatal spot, on the morning of the 2d of October, he perceived that he was to perish on a gibbet, he exclaimed, 'It is but a momentary pang,' and gave no further expression to his feelings. He died with the respect even of those who had found themselves obliged to execute him. 'André,' said Washington, in a letter to a friend, 'has met his fate, and with that fortitude which was expected from an accomplished man and a gallant officer.' A monument was erected to his memory, at the public expense, in Westminster Abbey.

Whatever the books which are considered the standard authorities upon international law may say in reference to such a case as that of André, there is no good apology for his conduct. To say that he acted under the orders of an officer whom he knew to be playing the part of a traitor, cannot be considered as any exculpation. There would be no security for an army or a government if it were not to be at liberty, when it had them in its power, to punish persons detected in devising such plots as this of Arnold and André, under whatever subterfuge they might attempt to shelter themselves. The having recourse to the use of a flag of truce, in such circumstances, must be regarded as a mere trick. General Clinton and Arnold were the great culprits, of whom the latter only has received his due share of opprobrium.

To his last moment André had cherished the hopeless passion which had driven him from his country and his early pursuits. In a letter written after his capture, which has been printed, he states that when he was stript of everything, he had concealed the picture of Honoria S—— in his mouth. This lady, although it does not appear that he had been informed of the event, had died of consumption only a few months before.

This unfortunate officer was a person of cultivated mind and elegant accomplishments. He excelled in painting and music, and was also no despicable writer of verse. His humorous poem, entitled the *Cow-chase*, which appeared in three successive portions at New York, in 1780, the last being published on the very day on which its author was taken prisoner, is a production of decided talent. It is in the style of Cowper's *John Gilpin*, which celebrated poem was not written till some years later. For further particulars respecting the subject of this notice, see Miss Seward's *Monody on the Death of Major André*, 4to., London, 1781, from the notes and letters attached to which we have taken most of the facts of his private history; a publication by Joshua Hett Smith, Esq., (the person who acted as his guide on his return to New York,) entitled *An Authentic Narrative of the Causes which led to the Death of Major André*, 8vo., London, 1808; and an elaborate article in the *Encyclopædia Americana*, under the head of 'Arnold, Benedict.'

ANDREA VANNUCHI, called DEL SARTO, from the occupation of his father, a tailor at Florence, was born in that city, in the year 1488. He was initiated in the principles of design by Giovanni Barile, and he studied subsequently in the school of Pietro Cosimo. He learned little more from these masters than the mechanical practice of his art, but in the frescoes of Masaccio and Ghirlandajo, and in the cartoons of Michel Angelo and Leonardo da Vinci he found the principal elements of whatever excellence he

afterwards attained. His powers were first developed in some works executed in conjunction with a friend and fellow-student, called Francesco Bigio, for the churches and convents of Florence; but the great picture of St. John preaching, entirely by his own hand, established his claim to independent reputation, and it was considered that the work which immediately followed, the life of Filippo Benizi in ten compartments, for the church of the Servi, entitle him to rank with any competitor in his native city. Stimulated by this success, Andrea felt anxious to try his strength with his great contemporaries at Rome, and accordingly made a visit to that city. Vasari relates, that, on seeing the paintings of Raffaele, he felt so humiliated, that he returned immediately to Florence, without staying to investigate the great works which had impressed him with so painful a sense of inferiority. Other authorities affirm that he remained in the imperial city a considerable time, dividing his attention between the study of Michel Angelo, Raffaele, and the Antique; this account is by far the more probable, especially as the first works which he executed after his return to Florence manifest an obvious improvement in style. Among these, the most conspicuous were the Descent of the Holy Ghost, the Birth of the Virgin, and the Last Supper, painted for the monastery of the Salvi. Of the last picture Lanzi relates, that during the siege of Florence, in 1529, the soldiers having got possession of the suburbs, and having demolished the church and part of the monastery, on entering the refectory were struck with such reverence at the sight of the painting, that they remained awhile motionless, and then returned, without committing any further injury.

The increasing reputation of Andrea del Sarto procured him an invitation from Francis I. to visit the court of France, and that monarch expressed a wish to retain him altogether in his service. The political troubles of his own country, which rendered the pursuit of art a precarious and unprofitable employment, induced Andrea to embrace with eagerness the proposal of the French monarch, and he set out for his court, where he was received with the most flattering demonstrations of kindness and respect. His first performance was a portrait of the Dauphin, for which he was paid the sum of 300 gold crowns; he painted also for the king the superb picture of the Charity, which is now in the French museum. A multitude of commissions poured in upon him from the principal nobility, and every circumstance seemed to conspire for his honour and advantage. He was engaged on a picture of St. Jerome for the queen-mother, when in an evil hour he was induced by earnest solicitations, sent by his wife and friends from Florence, to return to that city. He obtained permission from Francis I. to depart, on the assurance that the sole purpose of his journey was to transport his family to France; and the king, being desirous to avail himself of Andrea's taste and judgment in the acquisition of works of art, intrusted him with large sums for the purchase of pictures and statues. Andrea was perhaps, originally, neither profligate nor unprincipled; but his character was impaired by that want of moral firmness, which, beginning in weakness, too often ends in vice. His wife was improvident, and he was surrounded by dissipated acquaintances; and he expended in a round of expensive pleasures, not only the money with which Francis I. had liberally rewarded his services, but that also which the monarch had consigned to him for the purpose of selecting objects for his museum. Of course, he never returned to France. Indigence came upon him, and the remorse with which he was continually tormented from the consciousness of ingratitude towards his royal benefactor, was aggravated, not only by the desertion of his gay friends, but by that of his wife also, who fled from him, leaving him a prey to despondency and distress. His afflictions were terminated by the plague which visited Florence in 1530, and carried him off in his forty-second year.

The genuine productions of Andrea del Sarto are not frequently seen out of Florence, but they abound in the churches, convents, and palaces of that city. His style is so various that it is difficult to say what was the natural bent of his mind. He was not incapable, when the subject demanded it, of impressing his works with an air of stern grandeur, whether in relation to the style of design, or to the effect of *chiar' oscuro*; but his more general characteristics are those of harmony and suavity; his colouring is sometimes most delicately tender. He was so expert in mechanical practice, that a copy made by him of a portrait

of Leo X., by Raffaele, deceived even Giulio Romano, although he had inspected the progress of the original, and had even assisted in the execution of it. One of the most pleasing of Andrea del Sarto's pictures, although by no means an example of his general style, is that of the Holy Family, now in the Louvre at Paris, in which St. Joseph reposes on a sack of corn. The panegyrists of Andrea have asserted that if he had studied longer in Rome, he would probably have rivalled the great works of Raffaele and Michel Angelo; but without conceding such extravagant praise, it is quite enough for his reputation that he established it while those great artists were still practising, and that his name has kept its place amidst all the revolutions of taste, during a lapse of three hundred years.

ANDREASBERG, (Mount of St. Andrew,) the second in importance of the mountain-towns of the Upper-Harz, is situated in the province of Grubenhagen, in the kingdom of Hanover, and crowns an eminence which stands at an elevation of 1936 feet above the level of the sea. The neighbourhood is rich in mines, yielding silver, copper, iron, cobalt, and arsenic; and these, as well as the spinning of yarn, lace-making, and the rearing of cattle, afford profitable employment to its inhabitants, who are above 4000 in number. It has a public school for the middling classes. In 1728 a piece of silver ore, weighing eighty pounds, was found in one of the mines near the town, and presented to the Cabinet of Natural History in Göttingen, from which it was, however, stolen in 1783. Andreasberg lies about fifteen miles north of Goslar. The mountain of this name is the highest point in the Harz at which slate is found.

ANDREWEA, (also called Endery or Endri,) is a principality of the Kumükian Tartars, lying along the Kasma, between the river Aksai and the Caspian; about 25 miles west of the last-mentioned sea. It forms at present one of the districts composing the government of Caucasia in Russia in Asia, and embraces the peninsula and gulf of Agraschanskoi. Its surface presents an intermixture of fertile plains and arid wastes of sand; produces grain, and abounds in mineral waters and springs of naphtha. Andreewa is likewise the name given to its capital, and is the mart to which the Lesghian tribes resort for the purpose of disposing of the produce of their depredations. It is an open town situated on the Aktash, at the foot of Mount Tshumlu, and contains upwards of 3000 houses, with a population, which is stated by some writers at 12,000, and by others at 15,000 souls. Andreewa was, not long since, an avowed asylum for all the vagabonds and freebooters in the Caucasian regions, and is to this day a thriving market for the sale of slaves. In this last respect it runs a miserable race of competition with the town of Aksai, on the river of that name and in the same principality. It is the seat of some Mohammedan schools, to which the Circassian Mollahs are sent for education. Though little deserving the name of education, yet the smattering of reading and writing which they here acquire, is sufficient to furnish them, upon their return amongst their fellow-countrymen, with the means of keeping the tenets and prejudices of Mohammedanism alive in their bosoms, and thus maintaining a wall of separation between the native and his heretic fellow-subject of the Greek faith.

ANDREOSSI, Count, was born at Castelnauvady in the province of Languedoc, in March, 1761. His family was of Italian descent. At the age of twenty he was made lieutenant of artillery. In the beginning of the French revolution he shared in the general enthusiasm for the new order of things, and he afterwards served under Bonaparte in the early Italian campaigns, where he distinguished himself at the siege of Mantua, in 1796. He next followed Bonaparte to Egypt, where he took a conspicuous part both in the military and the scientific labours of that celebrated expedition. He was appointed a member of the Institute of Cairo, and wrote several memoirs, *On the Lake Menzaleh, On the Valley of the Natron Lake, On the Waterless River, &c.* When Bonaparte returned secretly to France, Andreossi was one of the few officers who accompanied him, and he ever after proved devoted to the fortunes of his great commander. Andreossi served in the so-called Gallo-Batavian army under Augereau on the banks of the Mayne. After the peace of Amiens he was sent as ambassador to England. When Napoleon assumed the imperial crown, Andreossi was made inspector-general of artillery, and a count of the new empire. He went afterwards as ambassador to Vienna, and having

quitted his post when the war broke out again between Austria and France in 1809, he was present in the campaign of that year, and was appointed governor of Vienna after the taking of that city. He was next sent as ambassador to the Ottoman Porte, in which important situation he won the general esteem of both Franks and Turks. After the abdication of Napoleon in 1814, Louis XVIII. recalled Andreossi from Constantinople, and sent him at the same time the cross of St. Louis. Andreossi was living in retirement when Napoleon landed from Elba, but he then appeared again on the political stage to assist his old master in his last struggle. He was created a peer during the hundred days. After the battle of Waterloo he withdrew again to private life, and busied himself in revising and publishing several interesting memoirs which he had written during his residence in Turkey. His work on *Constantinople et le Bosphore de Thrace* is deservedly esteemed. His memoir *On the Springs and Conduits by which Constantinople is supplied with Water*, contains much curious information on the art of hydraulics as practised by the Turks. Andreossi had written also in 1810 a *History of the Canal of Languedoc*, in which he claimed for one of his ancestors, François Andreossi, the principal merit in the planning of that great work, which had till then been ascribed to the engineer Riquet. This book was the occasion of much controversy with Riquet's descendants, in which the astronomer, De la Lande, sided with the latter. Count Andreossi died in September, 1828, at Montauban.

ANDREW, kings of Hungary. [See HUNGARY.]

ANDREW, SAINT, one of the apostles, the brother of St. Peter. His father's name was Janus. From the first chapter of St. John's Gospel, he appears to have been one of the followers of John the Baptist, whom he left at the call of Jesus, being the first disciple whom the Saviour is recorded to have received. Andrew introduced Peter to Jesus. According to St. Matthew and St. Mark, Jesus found Peter and Andrew together, following their occupation of fishermen, as he was walking by the sea of Galilee, and called them, when they immediately left their nets and followed him; but this is supposed to have happened some time after the first interview recorded by St. John. That evangelist mentions Andrew as the disciple who intimated the presence of the lad with the few loaves and fishes, when the miracle of feeding the five thousand was performed. Such is nearly all that is stated respecting this apostle in Scripture.

The ecclesiastical historians, however, have professed to give us accounts in considerable detail of the latter part of his life. According to Theodoret, he employed himself for some years in journeying and preaching the faith throughout Greece; but Eusebius, and other writers, speak of Scythia as the province of his missionary labours. The common statement, however, is, that he suffered martyrdom at Patræ, now Patras, in Achaia, having been put to death by order of Egæus, the pro-consul of that province. The year in which this event took place is not mentioned; but both in the Greek and in the Latin church the festival commemorative of it is held on the 30th of November. The notion that St. Andrew suffered on a cross of the form of the letter X, appears to be of considerable antiquity; but the oldest writers say that he was nailed to an olive-tree. They used to keep, in the church of St. Victor at Marseilles, what was affirmed to be the very cross on which he had been suspended; it was enclosed in a silver shrine, and was of the common form, that is, with one limb perpendicular, and the other horizontal.

The Scottish historian, Fordun, delivers a legend respecting the relics of St. Andrew, which several of his countrymen have copied. In the middle of the fourth century, it seems, the bones of the saint, which still remained at Patræ, were in the custody of Regulus, an abbot, or, as other accounts style him, a bishop, of the Greek church. In the year 345, the Emperor Constantius II. gave orders that these precious remains should be brought to Constantinople; but on the third night before they were removed, an angel appeared in a vision to Regulus, and ordered him to abstract from the chest in which they were kept the upper bone of one of the arms, three of the fingers of the right hand, and the pan of one of the knees. Some accounts add a tooth to the list of items. Regulus having done as he was commanded, was, some years after, directed by another vision to take his departure, with the relics, from Patræ; and, having accordingly set out, he was, after

a long voyage, shipwrecked with his companions in the bay of St. Andrews, in Fifeshire, then forming part of the territory of the Picts. Hungus, the Pictish king, received the strangers with great hospitality; and by their instrumentality, he and his subjects were soon after converted, when a Christian church was erected at the place where the missionaries had been driven on shore, and was dedicated to the apostle, the fragments of whose skeleton they had brought with them. Such is said to have been the origin of the city of St. Andrews, and of the assumption of St. Andrew by the Scotch as their patron saint.

Several of the fathers, but none earlier than the seventh century, cite a book called the *Acts of St. Andrew*, professing to be written by that apostle, but which they condemn as a forgery of the Manicheans, or other heretics. There is still extant a narrative bearing this title, but professing to be written by the priests of the Church of Achaia, and entirely different from the former. It may be found in the sixth volume of Surius's *Vita Sanctorum*, and in other collections indicated by J. A. Fabricius in his *Codex Apocryphus Novi Testamenti*. Mention is also made in a decree of Pope Gelasius II., who flourished in the beginning of the twelfth century, of a Gospel of St. Andrew. His holiness condemns it as spurious; but it does not now exist.

ANDREW, (ST.) [See ISLE OF BOURBON.]

ANDREWS, (ST.) an ancient city of Scotland, on the coast of Fifeshire, and on the small bay of St. Andrews. The direction of the side of the bay on which the city stands is W.N.W. and E.S.E., and St. Andrews is open to the N.E. winds, which prevail greatly in April and May, and bring with them cold, unpleasant vapours, which load the air and check vegetation. The climate is, however, in general healthy, except for persons who are liable to rheumatism, or have weak lungs. Since the establishment of hot baths, the city has been much frequented as a favourite watering quarter.

The town stands on a lofty cliff or rock, and on a sort of peninsula, formed by the bay and the 'burn of Kinness,' or the 'Nether Burn,' a small stream which, skirting the town on the southern and eastern sides, forms, at its mouth, a harbour, guarded by piers, and capable of receiving vessels of 300 tons at spring-tides. On the N.W. of the town, 'the Links,' uneven downs formed by the sea, stretch away for nearly two miles to the mouth of the river Eden, and are used for the game of golf, which is much practised. There are similar downs S.E. of the town. The extremity of the peninsula on which the town stands is occupied by the ruins of the cathedral and by some other interesting remains of antiquity. From this part, the three main streets, North Street, Market Street, and South Street or Shoe-gate, diverge; the principal and most southern of them, South Street, runs nearly east and west. These three streets are intersected at right angles by the Lanes or Wynds. There was once a fourth street, called Swallow Street, running to the north of the others and inhabited chiefly by the merchants, but this has disappeared, and the site of it is occupied by a public walk called the 'Scores.'

Before the Reformation, St. Andrews was an opulent and commercial city. To its annual fair, which commenced in the month of April, and lasted several weeks, from 200 to 300 vessels from all parts of the commercial world resorted. When the town was in its most flourishing state, in the fifteenth and beginning of the sixteenth centuries, there were in it sixty or seventy bakers, and as many brewers. After the Reformation, it gradually decayed, and moreover suffered in the great civil war: so that Dr. Johnson, who visited it in 1773, thus spoke of it, 'One of its streets is now lost; and in those that remain, there is the silence and solitude of inactive indigence and gloomy depopulation.'

By the exertions of individuals, however, a considerable revival has been effected, and many additional improvements are in progress. The principal street is well built, straight and broad; and in this, as in the other two, the houses, which are of stone, are commonly three stories high; while the lightness of the numerous modern edifices diminishes the sombre appearance resulting from the general antiquity of the buildings.

The parish Church of St. Andrews is in South Street, and is a spacious structure, first erected in 1112, and repaired, or rather rebuilt in 1797. It is 162 feet long, and 63 broad, and will accommodate 2500 persons: on the wall inside, is a monument to the memory of Archbishop

Sharp, erected by his son, exhibiting, in rude sculpture, the murder of the unfortunate prelate, and setting forth his praises in a long inscription. There is a spire to the church. The chapel of St. Salvator's college is a handsome edifice with a Gothic front, situated in North Street. Within is the handsome monument of Bishop Kennedy, founder of the college. It is the place of worship for the parish of St. Leonard, which comprises a few districts in the town and neighbourhood; and the ministry of which was for a long period held by the principal of the United College, but this is not the case now. There are three dissenting places of worship, one Episcopal, the others belonging to the Burghers and Independents. The town house, or tolbooth, is in the centre of Market Street; and contains one or two antiquities of local interest, but little else worthy of notice. St. Andrews was made a Royal Burgh in 1140: the magistracy consists of a provost, a dean of guild and four baillies. The town, conjointly with Cupar, Anstruther Easter, Anstruther Wester, Crail, Kilrenny, and Pittenween, sends one member to parliament. The trade of St. Andrews is small. In 1792, a factory for sewing and tambouring muslin was established, which gave employment to above 100 girls as apprentices; but as this branch of industry is unnoticed in later authorities, it is probably extinct. The manufacture of sail-cloth was established about a year after, and promised to become considerable; but this has also been given up. A great number of golf balls are made. About 4000 annually are used in the town and neighbourhood, and about 9000 are sent to Edinburgh, Glasgow, and other places. Some ten or eleven vessels belong to the port, and are chiefly employed in the coasting trade; and eight or ten boats are engaged in fishing. The population of the parish of St. Andrews, which extends about nine miles in length, was in 1831, 5621. There are five fairs in the year.

The university of St. Andrews consists at present of two colleges; viz. the United College of St. Salvator and St. Leonard (formerly distinct), in which the several branches of general literature and science are taught; and the New College, or St. Mary's, which is appropriated to the study of divinity, or of kindred subjects, and is attended solely by theological students. There is no medical or legal school connected with either college.

This university, the most ancient in Scotland, was founded in the year 1411, by Henry Wardlaw, then Bishop of St. Andrews, who granted a charter with the immunities and powers usually granted to universities, to an association of certain men of learning, who had about a year before commenced a course of public lectures on divinity, the civil and canon laws, logic, and philosophy; and had attracted a considerable concourse of students. The charter of Bishop Wardlaw was confirmed by the pope; and in 1431, further immunities were granted by King James I. of Scotland, and ratified by succeeding sovereigns. The seat of the university at this period was the spot where St. Mary's College now stands, and was called the *Pædagogus*.*

St. Salvator's College was founded in 1455, or 1458,† by James Kennedy, nephew of James I., and successor of Wardlaw in the see of St. Andrews, and endowed with sufficient revenues for the maintenance of a principal, six fellows, and six poor scholars. The buildings of this college in North Street, form a quadrangle of 230 feet long by 180 broad, into which quadrangle you enter from the south by a gateway, over which is a steeple 156 feet high, and a clock: to the right of the gateway is the chapel already mentioned. The buildings of this college having gone very much to decay, a grant has been made by government, and a new structure has been erected on the east side of the quadrangle. St. Salvator's College is the seat of the United College.

St. Leonard's College was founded in 1512, by Prior Hepburn, and endowed by him from the revenues of an hospital for pilgrims, from the funds of the parish of St. Leonards,‡ and from property of his own. The before-mentioned hospital was made the seat of the college.

In 1747, it was found expedient to unite the two colleges. The joint establishment was accordingly transferred to

* A school had been taught on this spot even before the foundation of the university, but it was superseded by that institution.

† Bishop Kennedy seems to have set apart the revenues destined for the college, and to have granted the first charter in 1455: the second charter is dated in 1458. This last is very long, and contains all the statutes of the college.

‡ Authorities vary here:—in Sinclair's *Statistical Account* it is stated, that the parish was probably formed about the time of the erection of the college.

St. Salvator's, and the buildings of St. Leonard's were sold, and converted into dwelling-houses.

St. Mary's College was formed out of the original seminary or pedagogy of Bishop Wardlaw, by James Beaton, Archbishop of St. Andrews (for the see had been made archiepiscopal in the time of Bishop Kennedy's successor); and his designs were further carried on by Cardinal Beaton, the archbishop's nephew and successor in the see, and by Archbishop Hamilton, who succeeded the cardinal. The enlargement of the pedagogy by Archbishop Beaton appears to have been begun in 1538. In 1579, the college was remodelled under the direction of the celebrated George Buchanan. The buildings occupy two sides of a quadrangle, on the south side of South Street; and have lately been substantially and tastefully repaired.

The curriculum, or course of study in the arts, extends over four sessions. These studies are pursued at the United College, and the session lasts from the end of October to the beginning of May. St. Mary's College has three professors, viz., of divinity, church history, and oriental languages, besides a principal, who also reads lectures on divinity; and the complete course of a student includes four years, but the session is only of four months. The study of mathematics has always formed a principal branch of instruction at St. Andrews.

In each of the colleges are lodging-rooms for the students, which have been now for some time unoccupied; and there are bursaries or endowments, entitling the holders to a certain income for so many years. Fifty-five belong to the United College, and seventeen to St. Mary's. (*Journ. of Educ.* vol. iv., p. 36.) The students of St. Mary's pay no fees. The emoluments of the professors arise from their salaries, or, at the United College, from these with their fees in addition. The number of students at the university was, in 1826-27, 320. (*Journ. of Educ.*) Those who belong to the United College are required to attend divine service twice in the Sunday at the college chapel; except in the case of Dissenters, who are allowed to attend their own places of worship.

The revenues of the United College are somewhat more than 3000*l.* per annum, including the sums received on account of the bursaries; the disbursements in 1823 (the latest statement given in the report of the commissioners appointed by royal authority, some years ago, to visit the Scotch universities) rather exceeded the income; and there is besides a considerable debt. The revenue of St. Mary's, on the average for seven years before 1826, was rather greater than the expenditure, and amounted to above £1000. The university has little property distinct from that possessed by the colleges individually, except the library, which is entitled to a copy of every work entered at Stationer's Hall, and contained upwards of 40,000 volumes in 1830. The officer of highest dignity is the chancellor, but his office is merely honorary: the rector (who is appointed by the principals, the professors, and by the students of theology, and of moral and natural philosophy) is the acting head. He is appointed annually, and one of the principals, or of the professors of divinity or church history, must be elected. He is *præses* of the *senatus academicus*, by which body, consisting of the principal and professors of each college, all the academical degrees are conferred. The flourishing trade once carried on in medical degrees has been given up. A grammar-school, and a school for English writing and arithmetic, are under the patronage of the corporation. Dr. Bell, the founder of the Madras system of education, has given a splendid donation of 45,000*l.*, 3 per cent. stock, for the establishment of a comprehensive seminary of education in this his native city, to be called the Madras College. The buildings for this school, forming a large and handsome edifice on the south side of South Street, some distance west from St. Mary's College, are nearly completed.

The antiquities of St. Andrews are numerous and interesting. Those which are ecclesiastical stand near together just by the harbour. The most antient is the chapel, (situated about forty yards S.E. of the cathedral,) the foundation of which the legend ascribes to St. Regulus, (commonly called St. Rule,) the traditionary founder of the place, but which is probably 1000 years old at least. The story is, that a holy person, the abbot of a monastery at Patræ, (Patras,) in Achaia, having been warned in a dream to depart without delay to an island called Albion, situated in the farthest extremity of the Western world, set sail with

seventeen monks and three nuns, carrying with him some of the relics of St. Andrew; and was wrecked in the bay now called St. Andrews, (the shores of which were then covered with wood, and infested with huge wild boars,) and lost all except his companions and the precious relics. He succeeded in converting the King of the Picts, who then governed this part of the country, (near the end of the fourth century;) and the grateful prince erected for the saint the chapel of which the ruins still remain. They consist of the walls of the chapel, inclosing an area of thirty-one and a half feet by twenty-five. The greatest dimension is from east to west. At the west-end is the tower, a square building with a base of twenty feet each way, (measured outside of the walls,) and 108 feet high. There is no trace of the Gothic architecture in these ruins, which are doubtless very antient. Adjoining the west side of the tower was another chapel of which no part remains.

The cathedral of St. Andrews was nearly 160 years in building, (A.D. 1159, or 1161 to 1318,) and was demolished in one day, in June 1559, by a mob excited by a sermon of the celebrated John Knox. The eastern gable with its two towers is, however, still standing; and there remains also one of the towers of the western gable, part of the south wall from the western gable to the south transept, and the west wall of the south transept. The towers are each 100 feet high from the ground to the summit; they rose considerably above the roof of the church. The architecture varies, Saxon and Gothic (or late Norman and early English) being intermixed. The western end was of later erection, and in a much richer and more ornamented style than the other; and exceeded it in width by ten or twelve feet. The length of the cathedral, as nearly as can be measured from the unevenness of the ground, was 350 feet, (Sinclair's *Statistical Account of Scotland*), or 370 feet. (Grierson, and *Beauties of Scotland*), and the breadth of the transept from north to south was 160 feet, (Sinclair's *Statistical Account of Scotland*), or 180 feet, (Grierson.) The stone is by no means of so durable a nature as that with which St. Regulus's chapel is built; and the dilapidation has been further increased by the use of the materials for later erections. The ruined church of St. Leonard's adjoins the college of that name.

An extensive wall about 870 yards in length, twenty-two feet high, and four feet thick, with sixteen round or square turrets at different distances, was erected by Prior Hepburn (the founder of St. Leonard's College) in the beginning of the sixteenth century, to enclose for nearly the whole of their circuit the grounds of the great priory of St. Andrews, which had been erected about A.D. 1120. The enclosure is about eighteen acres, and contains the ruins of the cathedral and St. Rule's chapel, besides the relics of some other buildings belonging to the priory. This wall having been constructed of durable stone is tolerably entire, and has three gates still standing; one, a stately gothic arch, fronts the end of South Street.

There are some relics of two monasteries, one of the Dominicans, founded by Bishop Wishart in 1274, and the other of the Observantines (a species of Franciscans), founded by Bishop Kennedy at least 150 years later. Part of one of these edifices, though it is not decided to which of the orders it belonged, is used for the grammar-school, and stands in South Street, about 200 yards from the west port; it has, however, been entirely modernised. Another fragment of the same convent with an arched roof is, perhaps, the most beautiful specimen of pointed architecture in St. Andrews. The other convent was about 104 yards from the west port of North Street outside of the town. Both were demolished in consequence of Knox's preaching in June, 1559, when the cathedral was destroyed.

On the shore of St. Andrew's Bay, on a ridge or cliff, washed on the N. and E. sides by the sea are the ruins of the castle, which serve as a land-mark to seamen. There are some parts of the walls standing on the N. and E., but others have fallen from the encroachment of the sea, which has here gained considerably on the land, while a little way N.W. of the castle, (on 'the Links,') as we have seen, it has thrown up earthy matter. The keep or donjon at the north-west corner is entire. This castle was built by Bishop Roger about A.D. 1200, and subsequently enlarged. In 1336, it was taken and garrisoned by Edward III. of England; re-taken the following year, and nearly demolished. Bishop Trail repaired it towards the end of the fourteenth century, and it became the episcopal residence. It was

further repaired and beautified, and new works were erected by Cardinal Beaton in 1546; but it was demolished by an act of council in or about 1547, and though it was again partially repaired by Archbishop Hamilton, it never recovered from this overthrow.

In the cliff between the harbour and the castle is a singular cave, consisting of two apartments.

St. Andrews was the scene of several remarkable events, during the progress of the Reformation in Scotland. The fires of persecution were repeatedly kindled, for the town was the ecclesiastical metropolis of the kingdom, and the stronghold of the Catholics. Here in 1527 Patrick Hamilton, the first Protestant martyr in Scotland, was burned; and in 1545, Wishart, one of the most eminent of the Scotch reformers, suffered; Cardinal Beaton, the then archbishop, looking on from a window of the castle. The martyr, with his dying breath, foretold the downfall of his persecutor, and his prophecy was remarkably verified about a year after. Norman Leslie, son of the Earl of Rothes, with fifteen associates, proceeded to the castle, and with great address and resolution cleared it of the cardinal's retinue, and of the workmen employed in the repairs or new erections, amounting altogether to 150 persons, and proceeding to the cardinal's chamber, deliberately murdered him. The conspirators with their friends held out in the castle for several months against the troops of the government aided by a body of French; but were at last obliged to surrender upon terms. It was upon this surrender that the act of council for the demolition of the castle was issued. The murder of Archbishop Sharp, in 1679, took place on Magus Moor, about three miles S.W. of St. Andrews, and within sight of the town.

St. Andrews is thirty-nine miles N.N.E. of Edinburgh; and in lat. 56° 19' 33" N., long. 2° 50' W. from Greenwich.

It is said that the name of the district where St. Regulus arrived was Mucross; and the promontory on which the city stands was called Kilrymont till the middle of the ninth century. The navigation of the bay is dangerous. (Grierson's *Delineations of St. Andrews; Beauties of Scotland*, and Sinclair's *Statistical Account of Scotland*.)

ANDREWS (LANCELOT), an eminent English prelate, was descended from an ancient Suffolk family, and was born in the parish of All-Hallows Barking, London, in 1565. His father, Collier says, was a merchant of good repute;—according to the *Biographia Britannica*, he had spent the most part of his life at sea. Young Andrews was educated first at the Coopers' Free School at Ratcliff, and then at Merchant Taylors' School, from which he was sent to Pembroke Hall, Cambridge, by Archdeacon Watts, on one of the exhibitions founded by the latter in that College. He greatly distinguished himself at the University by his studious habits and extensive acquirements; and also in certain lectures which he read as catechist displayed the first promise of that talent for pulpit oratory for which he was afterwards celebrated. Having taken orders, he soon became known as a preacher. His first patron was the Earl of Huntingdon, who took him with him to the north of England; but he had not been long there before he obtained the notice of Walsingham, the Secretary of State, who gave him first the lease of the parsonage of Alton in Hampshire, and soon after obtained for him the vicarage of St. Giles's Cripplegate, London. To this preferment were afterwards added the dignities of prebendary and canon residentiary of St. Paul's, and prebendary of the collegiate church of Southwell. The mastership of Pembroke Hall, and the appointment of chaplain in ordinary to the queen followed; and so greatly was her majesty delighted with his manner of preaching, that she was not long in giving him a stall in Westminster Abbey, a place which he soon exchanged for the deanery of that church. He held this situation when James I. came to the throne. With that monarch he immediately became a great favourite, and the bishopric of Chichester having become vacant, he was presented to it, and was consecrated on the 3d of November, 1605. The king at the same time made him his lord almoner. In 1609 he was translated to the see of Ely; and was soon after made a privy-councillor both for England and Scotland. When James, in 1617, visited the latter kingdom, Bishop Andrews was one of the persons by whom he was accompanied. In 1618, he was advanced to the bishopric of Winchester, and was at the same time made dean of the chapel royal. These were his last preferments.

He died at Winchester-house, in Southwark, on the 25th of September, 1626, and was buried in the church of St. Saviour's, where a handsome marble monument, bearing a long Latin inscription, was erected over his remains. His tomb was opened, and his coffin discovered, in the course of the recent reparation of the church.

The principal work which Bishop Andrews published during his life was a thick quarto volume, printed in 1609, with the title *Tortura Torti*; being an answer to a treatise in which Cardinal Bellarmine, under the name of Matthew Tortus, had attacked the doctrine laid down by King James in his *Defence of the Rights of Kings*, respecting the authority of Christian princes over persons and causes ecclesiastical. Andrews undertook his performance on the command of his majesty; and was considered to have executed his task with great ability. He is also the author of a *Manual of Private Devotions and Meditations for every Day in the Week*, and a *Manual of Directions for the Visitation of the Sick*. After his death, a volume, containing ninety-six of his sermons, was, by the direction of Charles I., printed under the care of Bishops Laud and Buckeridge; and another volume, consisting of a collection of his tracts and speeches, also appeared in 1629. His work, entitled *The Moral Law Expounded, or Lectures on the Ten Commandments*, was first published in 1642. His *Academica Sacra, or Collection of Posthumous and Orphan Lectures delivered at St. Paul's, and St. Giles's Cripplegate*, appeared in a folio volume, in 1657. Bishop Andrews was, also, one of the authors of the common translation of the *Bible*. The portions in which he was concerned were the Pentateuch, and the historical books from the Book of Judges to the Books of Kings inclusive.

All the writings of Bishop Andrews display abundant learning; but his eloquence, notwithstanding the delight it appears to have afforded his contemporaries, is but little calculated to please the present age. Overspread as it is with verbal conceits and far-fetched allusions, and exhibiting in this way a perpetual labour of ingenuity, it altogether wants that simplicity and directness of effect which is the soul of good writing. Not that there is not a great deal of excellent sense wrapt up in its tinsel tropes, and other puerile and grotesque decorations; but the whole life and spirit of every thought is most commonly suffocated under a load of dead verbiage. The bishop's style, however, would seem to have wonderfully fascinated every body in his own times. Fuller who is greatly taken with it, and who affirms that Dr. Andrews was 'an inimitable preacher in his way,' in an anecdote which he tells with the view of showing how difficult or impossible it was for those who attempted to copy him to match their model, unconsciously records a severe and, at the same time, well-deserved condemnation of the manner of writing which he so much admires. 'Pious and pleasant Bishop Felton,' he says, 'his contemporary and colleague, endeavoured in vain in his sermons to assimilate his style, and therefore said merrily of himself, I had almost marred my own natural trot by endeavouring to imitate his artificial amble.'

Bishop Andrews was all his life a hard student, and is stated to have made himself conversant with all the learning of his age. After he had been three years at the university, we are told, it was his custom to come up to London for a month every year; and during that space, which he spent in the house of his father and mother, he always put himself into the hands of a master, and studied some language or branch of science with which he was before unacquainted. Casaubon, Cluverius, Grotius, Vossius, and other eminent scholars of the time, have all highly eulogized his extensive erudition, which was wont, it appears, to overflow in his conversation, as well as in his writings. He was also celebrated for his talent at repartee, of which the following instance is told by the writer of a life of Waller, the poet, prefixed to his works. Waller having one day gone to see James I. at dinner, saw the Bishop of Winchester and Dr. Neale, Bishop of Durham, standing behind the king's chair, and overheard the following conversation: 'His majesty asked the bishops,—My lords, cannot I take my subjects' money when I want it, without all this formality in parliament? The Bishop of Durham readily answered, God forbid, sir, but you should; you are the breath of our nostrils. Whereupon, the king turned, and said to the Bishop of Winchester, Well, my lord, what say you? Sir, replied the bishop, I have no skill to judge of parliamentary cases. The king answered, No put off, my lord; answer

me presently. Then, sir, said he, I think it lawful for you to take my brother Neale's money, for he offers it.'

Bishop Andrews, we ought to add, adorned his learning and shining talents by the highest reputation for piety, hospitality, charity, and munificence. One of Milton's early Latin poems is an elegy on the death of this distinguished prelate, in which he is bewailed in a strain of the most impassioned regret and admiration.

ANDRISCUS. [See PHILIPPUS.]

ANDRO/MACHĒ, the wife of HECTOR. It is also the title of one of the extant tragedies of Euripides.

ANDRO/MACHUS, a native of Crete, and physician to the Emperor Nero. He was the inventor of a celebrated compound medicine called Theriacle (*Θηριακή*), the preparation of which he described in a poem which has been preserved in the collection of Galen's works.

ANDRO/MEDA, a constellation, so called by the Greeks from Andromeda, the mythological daughter of Cepheus and Cassiopeia, who was bound to a rock and thus exposed to a sea-monster, from whom she was delivered by Perseus. This constellation occupies a considerable region of the heavens below Cassiopeia, by which it may be thus found. A line drawn through the brightest star of the five in Cassiopeia, marked β , and the pole star, passes through a star of the first magnitude in the head of Andromeda, marked α , and called Alpherat. A line drawn through ϵ Cassiopeia, at the other corner, and the pole star, passes through Almach in the foot of Andromeda, marked γ , while in the line between the two stars thus found, lies Mirach, marked β , in the girdle of Andromeda. The following list, taken from the *Mem. R. Astron. Soc.* vol. v. shows the references to the different stars of this constellation in different catalogues. The first column contains the letter, by which the star is denoted; the second its number in Flamsteed's catalogue; the third that in the Astronomical Society's catalogue, and the fourth the magnitude of the star.

ANDRONI'CUS was the advocate of the Jews under the reign of Ptolemæus Philometor in their proceedings against the Samaritans in Egypt, who, by asserting the authority of the temple on Mount Garizim, or Gerision, against the temple at Jerusalem, occasioned a controversy which terminated in bloodshed. The Egyptian Jews (although they had built, about the year 150 B.C., an heretical temple of their own, in the province of Heliopolis) zealously defended the authority of the temple at Jerusalem. After the arguments were exhausted, both parties took up arms, and having found that blows could not decide the matter, they appealed to the King, Ptolemæus Philometor, who appointed a solemn day of judgment. In full court it was agreed, that those who were found in error should be killed for the bloodshed already committed. The Samaritan advocates, Sabbai (Sabbæus) and Theodosius, lost their cause against Andronicus, and were put to death. The arbitrary administration of justice in those times, and the character of Ptolemæus Philometor, render this account not quite incre-

dible. (See Josephus's *Antiquities*, lib. xiii. cap. 7, ed. Aureliæ Allobrog., p. 434; and Jost's *Geschichte der Juden*, vol. ii. pp. 308, 309.)

ANDRONI'CUS COMNENUS, emperor of Constantinople, was grandson of Alexis I. In his youth he distinguished himself in the army under his cousin, the Emperor Manuel, against the Turks and Armenians, but having entered into a treasonable correspondence with the King of Hungary, he was arrested and confined in a tower of the palace, where he remained twelve years. He contrived to escape, and after several romantic adventures arrived at Kiew, in Russia, where he won the favour of the Grand Duke Jeroslaus. Like Alcibiades, Andronicus could assume the manners of every country, and his athletic constitution could support the vicissitudes of all climates; he could pass suddenly from the fatigues and privations of the camp to a life of luxury and debauch. He was a great favourite with the fair sex, and he won the affections of no less than four royal princesses in succession, beginning with Eudocia, the emperor's niece, who for him forsook the palace, and accompanied her lover in his early campaigns. Andronicus, in his exile at Kiew, became instrumental in forming an alliance between the Russian prince and the Emperor Manuel, and thus obtained his pardon from the latter. He led a body of Russian cavalry from the banks of the Borysthènes to the Danube, and assisted the emperor against the Hungarians at the siege of Semlin. After the peace, having returned to Constantinople, he protested against the adoption of Bela, Prince of Hungary, who had married the only daughter of the emperor, as presumptive heir to the throne. Andronicus was himself next in the order of succession. The Emperor Manuel however having married a second wife, Maria, daughter of Raymond of Poitou, Prince of Antioch, had by her a son, who was afterwards Alexis II. Meantime Andronicus, who held a command in Cilicia, fell in love with Philippa, Maria's sister, who gave herself up to him, as Eudocia had done before. The emperor, although himself dissolute in conduct, reproved this connexion of Andronicus with his own sister-in-law; and Andronicus, being obliged to leave Philippa, undertook, accompanied by a band of adventurers, a pilgrimage to Jerusalem, where he won the favour of Almeric, the Christian king of that country, and one of the successors of Godefroy de Bouillon. Andronicus received from him the principality of Beroth (Berytus), on the coast of Syria. There he fell in love with a third princess, Theodora, the young widow of Baldwin III. King of Jerusalem, who was herself of the Comnenian line and a distant relation to Andronicus. She lived openly with him as his concubine, and had two children by him. Andronicus being no longer safe in Palestine from the hostility of the Emperor Manuel, repaired, accompanied by Theodora, to Damascus, where the Sultan Noureddin received him hospitably. From thence he travelled to Bagdad, and other parts of the east, and at last settled among the Turks in Asia Minor, whence he made frequent incursions into the Greek territories. For this he was excommunicated by the church and outlawed by the emperor. The governor of Trebizond having found means to seize Theodora and her two children, and send them to Constantinople, Andronicus in despair, made his submission to the emperor, and repairing to Constantinople, sued for pardon in the most abject manner. He was banished to Oenoe, a town of Pontus, on the coast of the Euxine, between Cape Heracleum and Cape Jasonium, where he remained till the death of Manuel, in 1180, and the disorders of a disputed succession, induced the patriarch and the principal patricians to recall Andronicus, as the only man who could restore peace to the empire. He arrived in the capital in the midst of acclamations, acknowledged the young Alexis as emperor, but arrested the empress-mother, who had been in some measure the cause of the troubles. Andronicus was associated in the empire as colleague and guardian to Alexis. He then developed his ambitious views. He first caused the empress-mother to be tried on a false charge of treasonable correspondence. She was condemned unheard, and was strangled, and her body thrown into the sea. He next murdered young Alexis himself, and then assumed the undivided authority as emperor in 1183. He married Agnes, Alexis's widow and sister to Philippe Auguste of France, who was still almost a child. 'Andronicus's short reign,' says Gibbon, 'exhibited a singular contrast of vice and virtue' when he listened to his passions, he was the

scourge; when he consulted his reason, the father of his people. In the exercise of private justice he was equitable and rigorous; he repressed venality, and filled the offices with the most deserving candidates. The provinces, so long the objects of oppression or neglect, revived in prosperity and plenty, and millions applauded the distant blessings of his reign, while he was cursed by the witnesses of his daily cruelties. The antient proverb, that bloodthirsty is the man who returns from banishment to power, was verified again in Andronicus. (*Decline and Fall of the Roman Empire.*) He put to death, or mutilated in a cruel manner, all those who, during his long exile, had traduced him, opposed his views, or insulted his misfortunes, as well as those who were the friends of the murdered empress and of her son. A wretch of the name of Aaron, who had been secretary to the Emperor Manuel, and had his eyes put out on account of treason, suggested to Andronicus not to content himself with blinding those he suspected, but to cut out their tongues also, by means of which they might still have injured him. Many of Andronicus's intended victims escaped to Nicæa and Prusa, where they made a stand, but were overpowered, and those unfortunate towns were treated with the greatest barbarity. At last, so many terrors drove the people of Constantinople to revolt; Isaac Angelus, one of the proscribed and a descendant in the female line from Alexis I., took refuge in the church of St. Sophia. A crowd assembled and proclaimed him emperor. Andronicus was then, with his young wife, in one of the islands of the Propontis; he rushed to Constantinople, but was overpowered, taken prisoner, and dragged to the presence of Isaac Angelus, who, without any form of trial, gave him up to the personal revenge of his enemies. He was insulted and tormented in every possible manner; his teeth, eyes, and hair were torn from him, and lastly, he was hung by the feet between two pillars. In his painful agony he was heard to appeal to heavenly mercy, entreating it 'not to bruise a broken reed.' At last some one ran a sword through his body, and put an end to his sufferings. This dreadful catastrophe happened in September, 1185; Andronicus was then past sixty years of age.

ANDRONICUS CYRRHESTES, an architect who constructed, or, at least, a person whose name is attached to, one of the existing remains of antient Athens, commonly called the Tower of the Winds; the building takes this name from the figures of the eight winds being cut in relief on the exterior wall of the building, with their names above them on the frieze. (See Spon, ii., p. 135, Amsterdam, 1679.) This monument stands to the north of the Acropolis, and is thus described by Vitruvius:—'Those who have paid most attention to the winds make them eight in number, and particularly Andronicus Cyrrhestes, who built at Athens an octagonal marble tower, and cut on each face the figure of the several winds, each being turned to the quarter from which that wind blows; on the tower he erected a marble column (meta), on which he placed a Triton of bronze, holding out a rod in his right hand; and he so contrived it, that the figure moved round with the wind, and constantly stood opposite to it; the rod, which was above the figure, showed in what direction the wind blew.'

This building was intended for a sun-dial, and it also contained a water-clock, which was supplied with water from the spring under the cave of Pan on the north-west corner of the Acropolis. Colonel Leake is disposed to assign the date of this building to about B.C. 159. (See Leake's *Topog. of Athens*; *British Museum, Elgin Marbles*, vol. i., p. 29.)

ANDRONICUS, LIVIUS. [See LIVIUS.]

ANDRONICUS PALÆOLOGUS, the elder, son of Michael, emperor of Constantinople, was raised by his father as his colleague to the throne in 1273, and after Michael's death in 1282, he reigned forty-six years more. The reign of Andronicus, like that of most Byzantine emperors, was continually disturbed by religious controversies, civil wars, and foreign attacks. In 1301, Othman first invaded the territory of Nicomedia, the passes of Mount Olympus having been left unguarded by the neglect or parsimony of the Byzantine court. A formidable host of Catalonian and other adventurers came to Constantinople in 1303, to give Andronicus their assistance against the Turks, but in fact to live at the expense of the empire, and to plunder both sides of the Channel. They defeated the Turks in Asia, but they ravaged the country, sacked Philadelphia, be-

sieged Magnesia, which had a Greek garrison, seized Gallipoli on the Hellespont, and behaved, in short, worse than the Turks themselves. Andronicus, partly by force and partly through bribes, succeeded at last in getting rid of these troublesome allies, at an enormous cost. In 1320, Michael, son of Andronicus, having died, Michael's son, Andronicus, distinguished by the historians by the appellation of 'the younger,' revolted against his grandfather; and after several years of a ruinous war, was crowned as colleague to the old emperor in 1325. Another sedition broke out in 1328, which ended in the abdication of the elder Andronicus, who retired to a convent under the name of the monk Anthony. He died in his cell four years after his abdication, and in the seventy-fourth year of his age. He was a weak and bigoted, though not unlearned, prince. It was during these disastrous wars between the two Andronici that the Ottomans effected almost without resistance the conquest of all Bithynia and advanced within sight of Constantinople, while other Turkish emirs took possession of Lydia and Ionia and the adjacent islands. The ruin of the seven churches of Asia was then consummated. Andronicus, the younger, attempted bravely to stem the torrent, but was defeated and wounded by Orchan, the son of Othman, who took Prusa, Nicæa, and Nicomedia. He was, however, spared the mortification of seeing the Ottomans on the European coast. He died in 1341, in the forty-fifth year of his age, leaving by his wife Jane or Anne of Savoy, a boy, John Palæologus, who was put under the guardianship of John Cantacuzenus. (Gibbon's *Decline and Fall*; the Byzantine historians Gregoras, Pachymer, and Cantacuzenus; and Hammer, *Geschichte des Osmanischen Reiches.*)

ANDRONICUS, RHODIUS, or the Rhodian. It appears from Plutarch, Strabo, Galen, Aulus Gellius, Ammonius, Simplicius, and other antient writers, that there resided at Rome, about a century before the birth of Christ, an eminent Peripatetic of this name, who had previously taught philosophy at Athens. He is said to have first arranged, indexed, and published the works of Aristotle, after they had been brought to Rome in the library of Apellicon of Teos, by Sylla; the manuscripts had been communicated to Andronicus by Tyrannion, the grammarian, who seems to have been originally employed to put them in order. Some of the authorities also refer expressly to the Commentaries of this Andronicus on certain of Aristotle's works. The first work, however, supposed to be by this writer, which was recovered in modern times, was a short treatise, published by David Hoeschelius, in 12mo., at Augsburg, in 1594, under the title of *Andronici Rhodii Peripatetici Philosophi Libellus Nēpi Παθῶν*. In his preface, Hoeschelius referred shortly to the different antient authors who had mentioned Andronicus. In 1607, Daniel Heinsius published, in a quarto volume, at Leyden, from a MS. which had fallen into his hands, a Greek Commentary, or Paraphrase, on Aristotle's *Nicomachean Ethics*, probably so named from having been originally addressed to his son Nicomachus. Heinsius accompanied the text of his author with a Latin translation; but although in the manuscript the work was attributed to Andronicus, the Rhodian, he did not consider himself warranted to insert that name in the title-page. The inscription on the manuscript, he says in his preface, was evidently by an illiterate hand; and he insinuates that there is no proof that Andronicus, although he arranged and indexed the writings of Aristotle, ever wrote a commentary on any of them. In 1617, however, he published a second edition of the Paraphrase at Leyden, in octavo, in which he entitles it *Andronici Rhodii Ethicorum Nicomacheorum Paraphrasis, &c.* In this edition the former preface is withdrawn, and another is substituted, in which he refers to the other antient authors, besides Plutarch and Strabo, who have spoken of Andronicus, and expresses his conviction that the work is really by him. He was well acquainted, he says, with the several passages in his newly-added authorities, which tend to render this not improbable, although they had escaped his recollection when he published his former edition. It is most likely that his attention was called to them by having, in the interim, met with the preface by Hoeschelius to the treatise *Nēpi Παθῶν*; especially as we find him now reprinting that treatise at the end of the Commentary. The next edition of the Commentary appeared at Cambridge in 1679. It professes to be an exact reprint from the text of Heinsius, but of which edition is not said, although Heinsius himself, in his

second preface, speaks of his first edition as being full of blunders. This second preface the Cambridge editor suppresses, and prints instead of it the other, which Heinsius had withdrawn. To that he adds another of his own, an inspection of which may possibly explain his curious selection from the two written at different times by his predecessor. It consists chiefly of an elaborate display, at full length, of passages respecting Andronicus from the writers previously indicated by Heinsius and Hoeschelius. All this learning the worthy editor evidently wishes to pass off as his own. Heinsius, accordingly, he gravely tells us, preserves a deep silence respecting his author; and to bear out this assertion he prints, as we have said, the original preface only of that eminent scholar. If Heinsius, however, is defrauded of some glory by this clever management, it must be confessed that he is only foiled at his own weapons, and receives no more than the treatment he had himself practised on Hoeschelius. The facts, we think, are worth recording as another illustration of the common saying, that there are tricks in all trades. It may be added, that in 1809 the curators of the Clarendon press at Oxford produced a fourth edition of the *Paraphrase of Andronicus*, in which with amusing scrupulosity they have followed the previous edition of the sister university in all particulars, the ingenious selection from the prefaces of Heinsius included.

After all, great doubts have been entertained by several critics as to the work being really the production of Andronicus the Rhodian. The different opinions upon the subject may be found in Bayle. Gabriel Naudé conceives Olympiodorus, who lived in the sixth century after Christ, to be the author. Saumaise (Salmassius) also is decidedly of opinion that it is not the work of the Rhodian peripatetic. Others have even attributed it to an Andronicus Callistus, a native of Thessalonica, who lived in the fifteenth century, and came to Italy after the taking of Constantinople. He gave lessons in Greek in different cities of Italy, Angelo Politian being one of his scholars; after which he came to Paris, and was the first who taught the language in the university there. He died in 1478. There is as much diversity of conjecture about the authorship of the short tract *Περί Πλάτωνος*; it is generally believed at any rate not to be by the author of the *Paraphrase*. It is stated in the *Biographie Universelle*, that a manuscript in the Imperial Library of France (now the Bibliothèque du Roi) cited by M. Sainte Croix, in his *Examen des Historiens d'Alexandre*, p. 524, attributes the *Paraphrase* to a Heliodorus of Prusse, that is, Brusa in Bithynia, we suppose.

An English translation of the *Paraphrase on the Nicomachea* appeared in a quarto volume at London, in 1807, with the following title: *The Paraphrase of an anonymous Greek Writer, hitherto published under the name of Andronicus Rhodius, on the Nicomachean Ethics of Aristotle*, translated from the Greek by William Bridgman, F.L.S.

ANDROS. [See BAHAMAS.]

ANDROS, an island of the Grecian Archipelago, lying off the S.E. end of Eubœa, from which it is distant six miles. It lies in a N.W. and S.E. direction, is twenty-one miles long and eight broad, with a population of about 18,000. The island is very high and mountainous, and the highest summits retain the snow during many months in the year. The town called Andros, or Castro, is on the eastern coast, besides which there are sixty-six villages scattered over the island. The soil is very fertile; and the numerous gardens, which are well laid out, produce excellent lemons, oranges, and pomegranates. Much wine is made, but all consumed by the inhabitants, who are great drinkers. Silk, to the amount of about 3000 pounds on an average, is exported annually. It is the practice to sow wheat and barley together, of which they make their bread, but there is not sufficient grown for the consumption of the island; the deficiency is easily made up from the neighbouring island of Eubœa. On the west shore, there is a port called Gabriel, partially sheltered by small islands from the S.W., but on this side of Andros there are no inhabitants, the coast being so very steep and rocky. The N.W. point, called Point Guardia, is in 37° 57' N. lat., 24° 42' E. long.

ANDROSCOGGIN, or AMARISCOGIN, a river of North America, which rises in about 45° 12' N. lat., 71° 15' W. long., on the east side of the highlands of New Hampshire and Maine. The Chaudière, which enters the St.

Lawrence opposite Quebec, has its sources near those of the Androscoggin, on the north and west side of the same highlands. The Androscoggin flows by numerous branches for about twenty-five miles south into a number of lakes, the chief and most western of which is Umbagog. The united waters forming a large stream flow from this lake in a western direction, which soon becomes a southern one, for thirty miles, under the name of Amariscoggin. The river having reached the northern base of the nucleus of the White mountains, turns due east, and piercing the mountain-chain flows in this direction for fifty miles. Here it makes another bend at right angles, and runs south for thirty miles, to the latitude of 44°. Below this point, by a curving course of twenty miles south-east, then east, and finally north-east, it joins the Kennebec at Merry-meeting Bay, about six miles above the town of Bath, in the state of Maine. The entire course, measured along the windings, as given by the maps, is not less than 200 miles. Below the mountains, the river is called the Androscoggin; it has no large tributaries, but is increased by numerous rivulets, and, like the other rivers of Maine, is, for its length, a very large one. The tide ascends the Androscoggin to near Durham, about thirty-five miles from the open ocean. Though obstructed by falls and shoals, like the Kennebec, both these rivers afford great facility for inland navigation: the chief article transported down them is timber. (See Darby's *Geographical View of the United States*.)

ANDUJAR, a town of Spain, in Andalusia, 38° N. lat., 4° W. long., 40 miles E.N.E. of Cordova, and 19 N.W. of Jaen, situated on an elevated plain at the foot of Sierra Morena. The river Guadalquivir embraces it on the east and south. The confined situation of Andujar renders it very sultry in summer, and subjects the inhabitants to bilious and putrid inflammatory fevers. The soil is very fertile, and produces wheat, barley, oil, wine, honey, and silkworms. The wines of Andujar are of a sharp taste, from their containing a large portion of tartar, but are rendered palatable by a particular process called by the Spaniards *arropar*, or sweetening. At Andujar the coolers, called *alcarrazas*, are manufactured of clay. The inhabitants are principally employed in agriculture, but there are also at Andujar some tanneries, and manufactories of soap and earthenware. There is a very ancient bridge of fifteen arches over the Guadalquivir, which is in a very bad state of repair. In January, 1823, the river overflowed, and damaged one of the piers; in consequence of which, two of the arches fell down. The general post and coach-offices for all Andalusia are at this town.

The population of Andujar amounts to 13,662 souls within the city, but a greater number of persons live in the numerous *cortijos*, farms, of the neighbourhood. Andujar contains five parish churches, six convents of monks, four of nuns, one hospital, one school, and two alms-houses, one for twelve old men and another for the same number of aged females. (See Miñano; Ponz, *carta v.*, n. 6—26, tom. xvi.)

ANDUZE, a town in France in the department of Gard. The town itself is ill built, but it is in a pleasant country, on the right or S.W. bank of one of the streams called Gardon, and which is distinguished as the 'Gardon d'Anduze.' The inhabitants, who amount to more than 6000, are mostly protestants, and are engaged in the manufacture of hats, cloth, serge, silk stockings, pottery, and glue, which find a sale at the great fair of Beaucaire, in the same department. [See BEAUCAIRE.] It is about 22 miles N.W. of Nîmes, the departmental capital.

ANEGADA, or the DROWNED ISLAND, one of the lesser Antilles, and the most northern of the group known as the Virgin Islands. The surface of Anegada is the production of lithophyte, based on a submarine foundation. The island is for the most part a dead level. On the south-east, there is a gradual rising of the ground from north to south to the elevation of sixty feet, and this is the highest point of the island. The south side is a continued mass of shelves, loosely covered with vegetable mould, mixed with sand. This mould is the result of sea-weed, which has lost its saline properties through exposure to the sun: it is light, and of a dark brown colour, and in many places covers the ground only to the depth of a few inches. Where the shelves are intersected by openings which occur continually and of various widths, larger quantities of sea-weed have been detained, and a considerable amount of vegetable mould has been accumulated, in which plants grow of a

healthy and vigorous appearance. The few trees found on the island grow in these situations. The northern, western, and eastern sides of the island are less favoured, being covered with sandy deposits thrown forward by the surf. The sand is frequently formed into hillocks forty feet high, and where they do not occur, detached masses of limestone and coral may be seen, many of which are upwards of thirty feet high. Behind these rocky hillocks some patches of productive soil are found, and these are cultivated as garden-ground by the inhabitants. Several ponds are met with on the surface of the island, from some of which considerable quantities of salt are gathered.

There is abundance of fresh-water on almost every part of the island, even in the immediate vicinity of the sea and of the salt-ponds. The water, by filtering through the surface soil, is very speedily deprived of its saline particles.

The vegetable productions of Anegada are not numerous, but it is singular that several of them are not observed in any of the other Virgin Islands. It appears probable that the seeds of these must have been carried there by currents, or conveyed by birds from the Spanish main.

Anegada is chiefly noted for the numerous wrecks which have happened on the reef by which its windward or eastern side is bordered, and which continues, under the name of the Horseshoe, about four leagues to the south-east, terminating seven miles from the east end of Virgin Gorda. The chief profit of the inhabitants comes from these shipwrecks; and, except on such occasions, the only labours in which they engage are those of raising provisions for their subsistence, and cultivating some small patches of cotton, the produce of which is taken for sale to the neighbouring island of Tortola.

The length of the island, in a direction east-south-east, is ten miles, and its greatest breadth four miles and a quarter. The south-east point of the island is in $18^{\circ} 44' N.$ lat., and $64^{\circ} 16' W.$ long. The population consists of eleven white and twenty-one coloured and black families. (See Purdy's *Colombian Navigator*, and *Journal of the Royal Geographical Society*, vol. ii.)

ANEMOMETER, from the Greek language, signifying *wind-measurer*, is an instrument for measuring the force of the wind, by finding what mechanical effect the wind to be measured will produce upon the apparatus. The first anemometer was invented by Wolf, and is described by him in his *Elementa Matheseos*, vol. ii. p. 319 (Geneva edition, 1746). It consists of four sails, similar to those of a windmill, but smaller, turning on an axis. On the axis is a perpetual screw, which turns a vertical cog-wheel round a second axis, placed transversely to the former. To the second axis is attached a bar, on which a weight is fixed, so that the sails cannot turn without moving round the bar in a vertical circle. When the wind acts upon the sails the bar rises, and this continues until the increased leverage of the weight furnishes a counterpoise to the moving force of the wind. The number of degrees through which the bar is moved to produce this effect is measured on a dial, the hand of which turns on the axis of the cog-wheel.

The principle of Dr. Lind's anemometer is as follows:—

A, a curved tube of glass, as represented in the figure, is partially filled with water. The bore of the tube is diminished at the bottom, as a check on the oscillations to which the water is subject from slight variations in the force of the wind. The wind acts upon the open end A, and depresses the water to B, until the column of water b C, the difference between the levels b and C, is a counterpoise to the force of the wind on B. This difference can be ascertained by the graduated scale. Hence, when the area of the bore at B is known, and the height of b C observed, the column of water is found the weight of which is equivalent to the force of the wind. The velocity may thence be found by observing (see *AERODYNAMICS*) that the velocities are nearly as the square roots of the resistances, and that the moving force of a wind of 20 feet per second on a square foot is 12 ounces.

The following table, calculated by Dr. Hutton, who made some experiments with Dr. Lind's anemometer, at Woolwich (which is given in his *Mathematical Dictionary*), may be used with that instrument, and indicates what velocity of wind corresponds to various differences between the levels.

Difference of Levels in inches.	Force of Wind in pounds.	Velocity per hour in miles.
$\frac{1}{4}$	1.3	18.0
$\frac{1}{2}$	2.6	25.6
1	5.2	36.0
2	10.4	50.8
3	15.6	62.0
4	20.8	76.0
5	26.0	80.4
6	31.3	88.0
7	36.5	95.2
8	41.7	101.6
9	46.9	108.0
10	52.1	113.6
11	57.3	119.2
12	62.5	124.0

In Regnier's anemometer, a bar, carrying a flat wooden surface at right angles to it, protrudes from a box, through a hole in the front of which it slides. This bar is met by a spring, which resists its further entry, until force is applied against the wooden surface. In the interior of the box, the under side of the bar carries rackwork, which plays on a cog wheel, the axis of which, passing through a side of the box, carries a hand round a dial-plate. The flat surface of wood is presented to the wind, which presses upon it and forces back the bar, carrying the cog wheel and hand through an angle, greater or less, according to the greater or less impulse of the wind.

Various other contrivances have been proposed; but those which we have described contain their main principles. For a table of the force of winds, see *AERODYNAMICS*.

ANEMONE is a genus of the natural order *Ranunculaceæ*, in which are comprehended many beautiful flowers. It consists of lowly herbs, usually perennials, with white or purple, or scarlet, or even yellow blossoms, in which there is no distinct calyx, and which are succeeded by a cluster of grains, each terminated by a long silky feathery tail. As the species generally grow on open plains or in high exposed situations, their feathery grains produce a singular shining appearance when waved by the breeze, whence has been derived their name (from the Greek *ἀνεμώνη*), which literally signifies Wind-flower, the appellation actually bestowed by the English.

All the anemones possess, in common with other *Ranunculaceæ*, the property of extreme acidity. The leaves of *A. pulsatilla* will raise blisters on the skin; if chewed, they produce irritation of the throat and tongue; and their roots, as well as those of *A. pratensis*, nearly related species, produce nausea and vomiting if administered in very small doses, on which account they have been strongly recommended by some medical men, in various complaints. The bruised leaves and flowers of *A. nemorosa* have been found to cure the tinea in the head of children. The following are the most remarkable species:—

1. *A. pulsatilla* or pasque flower; this grows wild upon exposed downs in various parts of England, as on the Gogmagog Hills near Cambridge, the heath at Newmarket, &c. It has large purple flowers and finely cut hairy leaves; and is very nearly the same as the *A. pratensis*, the use of which, in diseases of the eye, has been so strongly recommended by Baron Stoeck and others.

2. *A. nemorosa*, the wood anemone; found abundantly in woods all over England, covering the ground with its neat white flowers under the shelter of bushes as early as March and April. It is a perennial plant with knobby roots, and a short stem having one or two smooth, bright green, deeply cut leaves. It is poisonous to cattle.

3. *A. pavonina*, the Peacock anemone; a native of the vineyards in Provence, about Nice, and in other parts of the south of Europe. This is not very uncommon in gardens, where it is usually, but improperly, named *A. stellata*. It is known by its scarlet or scarlet and white flowers, which are usually double, and have their divisions very sharp-pointed. In habit it is like *A. coronaria*, for a variety of which it is often mistaken. It is one of the handsomest of the cultivated species.

4. *A. coronaria*, the common garden anemone. Found in a wild state in moist meadows in the south of France, Italy, and Greece, and different parts of Asia Minor; Dr. Russell speaks of it as abundant near Aleppo. In these places it is seen only in a single state, but even then sporting into a

variety of colours, the principal of which are white, scarlet, and purple in different shades. In the gardens it is too well known to require description: the single varieties are usually called *poppy anemones*; the double kinds owe their peculiar state either to a multiplication of the petals, or to a conversion of the stamens and pistilla into petals; these have been procured by patient cultivation for some hundred years, and are still improving. The method pursued has been to save seeds only from the kinds that have the greatest vigour, or the greatest tendency to a multiplication of their parts, and wherever a double flower is accidentally capable of producing seed, to prefer it to all others. By this means habits that were originally accidental become fixed, and capable of being further acted upon by the persevering gardener. A course of this sort patiently followed up, has enabled the Dutch to improve the race of anemones so much as to obtain them within a few years with stems nearly half a yard high, and with blossoms six inches across.

5. *A. stellata*; a native of various parts of Germany, France, and the Levant, is also often seen in our gardens, where it is called *A. hortensis*. It differs from the last in having smaller and narrower petals, very rarely double flowers, a greater tendency to purple in their colours, and much broader leaves. It is not so liable to vary as the last species.

Gardening books are filled with directions for the management of these plants; all of which, in this as in most other cases, may be reduced to a few simple rules, resulting, indeed, from experience, but which might have been just as well deduced from the consideration of the natural habits of the species. 1. They grow wild in rich and moist pastures; the soil for them should therefore be fresh loam, with as great a proportion of stimulating manure as they can be made to bear. 2. They are natives of the hottest parts of Europe, where the winter's cold is not more than the olive will bear; they should therefore never be exposed to the severest frosts of England, but should be protected by a covering of some kind, either in the shape of frames or a mulching of decayed tan. It is true that they are hardy enough to exist and flower without this care, but the beauty of plants protected is infinitely greater than that of such as are left exposed in the open border. 3. They commence their growth during the mild winters of their native countries, and are ready as soon as the spring is sufficiently advanced to start up into flower. As the summer advances, and the heat and drought increase, they perfect their seeds and lose their leaves, when they fall into a state of rest; summer and autumn are, therefore, their real winter, and, consequently, it is at this time they should be taken up and prepared for the succeeding season. 4. When they are in a growing state in their native countries, the sun's rays have but little force, and they are consequently not prepared to bear much exposure; for this reason, florists find it necessary to shade them, when they flower during the hot weather of our English summers.

Like all other rules in gardening, the above directions may be modified and departed from without any great evil; but if the object is to cultivate this class of flowers in the greatest perfection, and to improve their race, these rules will be found too important to be materially neglected.

For *A. Hepatica*, see *HEPATICA*.

ANEMOSCOPE, an instrument for determining the direction of the wind; usually constructed by connecting with the spindle of a weathercock the hand of a dial on which the points of the compass are marked.

ANETHUM. [See *FENICULUM* and *PIMPINELLA*.]

A'NEURISM, is a Greek word (*ἀνευρυσμός*), literally signifying, 'a widening, or extension': it is now used to signify a tumour, consisting of a preternatural enlargement of an artery. The artery is the only seat of this disease; and any artery of the body may be the subject of it, but it is much more common in some arteries than in others. The corresponding disease in a vein is termed *VARIX*.

An **ARTERY** is composed of three membranes which are firmly united, and form the walls of a strong, elastic, and extensible tube. These membranes are called *tunics* or *coats*. In the healthy state of the artery these tunics yield only to a certain extent to the impulse of the blood, so that the tube possesses only a certain diameter; but in a state of disease the impulse of the blood distends these tunics to a preternatural extent, causing that part of the artery which is diseased to swell out into a tumour or bag. The distension of the coats of the artery progressively increasing, they are at last capable of no farther stretch-

ing, and consequently are torn asunder and burst. But the inner and middle coats of the artery are not as extensible as the external coat; the two former coats are therefore ruptured a considerable time before the latter gives way, in which case the only proper coat of the artery forming the wall of the aneurismal tumour is the external. This coat in its turn getting progressively thinner and thinner as the dilatation goes on, at length bursts like the former; the blood escapes, and life is suddenly extinguished. But sometimes the tumour does not burst even after the rupture of the external coat of the artery; for there is placed around the artery a dense and strong membranous sheath consisting of what is termed cellular membrane, which sheath is far more extensible than any of the coats of the artery, and it is found that sometimes the aneurismal sac or the bag-like tumour which the dilated artery forms, consists only of this condensed cellular membrane, all the proper coats of the artery having been rent and destroyed by the progressively distending force. Thus an aneurism may consist simply of the dilatation of the coats of an artery without the rupture of any; or of the dilatation of some with the rupture of others; or of the rupture of all, the bag of the tumour being formed solely by the cellular sheath of the artery.

When the coats of the artery have burst and this portion of the tube is dilated into a sac, it is evident that this sac is beyond the direct current of the circulation, and that the larger the bag, the farther its contents will be from the influence of the direct current of the blood. The consequence is, that the blood contained in the aneurismal sac undergoes a peculiar change, a modification of the process of coagulation [see *BLOOD*]; the thinner part of the blood being removed, while a portion of the thicker part, or the fibrin, remains. In this manner there is left upon the internal surface of the sac a stratum of the thicker or fibrous part of the blood. Successive depositions are made of this fibrous part of the blood by which the cavity of the tumour is gradually diminished. At length the sac becomes entirely filled with this substance, which forms for it a firm plug. The deposition of this fibrin is not confined to the aneurismal sac, but is continued into the artery itself, both above and below its dilatation, until it reaches the next important ramification which is given off from the artery, where it stops. In this manner the circulation through the aneurismal portion of the vessel is prevented; the blood is determined into other channels; this portion of the vessel, being no longer of any service in carrying on the circulation, is blocked up, and in this manner is effected a spontaneous cure of the disease.

But this beautiful curative process, though it occasionally happens, is not the usual course. When the external coat or the cellular sheath of the artery are stretched beyond a certain point, it would seem that its vitality is diminished: at length a part of it mortifies or dies; an eschar is formed: the eschar sloughs away; an opening is thus formed in the tumour; the blood rushes out, and the patient dies. This is the mode in which the aneurismal sac bursts when the aneurism is situated on the external part of the body. But if the aneurism be internal the process is different. The tumour becoming thinner and thinner by successive distention, bursts suddenly by a crack or fissure, through which the blood is discharged.

The first symptom which denotes the formation of an aneurism, is the perception of an unusual throbbing in the diseased artery. If the situation of the artery be such that it can be seen or felt, a small tumour is manifest. This tumour, when carefully observed, is found to have a pulsatory motion, the pulsatory motion, as well as the tumor itself, disappearing when the part is compressed, but instantly reappearing on the removal of the pressure. Commonly, the tumour is without pain, and without any discoloration of the skin. The magnitude of the tumour, whatever its size when first discovered, is steadily progressive; in proportion as it grows larger the pulsatory motion diminishes, and when it has attained a very considerable size the pulsation is no longer perceptible. The tumour continually enlarging, produces a variety of effects on the parts with which it comes in contact. Some it pushes aside, others it carries with it, and others it destroys. The adjacent muscles, for example, whether they are situated directly over the aneurism, or are at one side of it, are usually stretched, displaced, dwindled, and sometimes entirely confounded with the contiguous parts. The nerves, too, are frequently pushed out of their natural situation, or, if they adhere to the sides of

the sac, as they often do, they are necessarily stretched as the tumor enlarges, and this distension of the nervous cords sometimes occasions intense pain. The cartilages and bones, pressed upon by the advancing tumor, gradually disappear, and at length are so completely destroyed that not the slightest vestige of them remains. In general, as long as the tumor is small, it is unattended with pain, but the changes which it produces in other parts, such as the stretching of the nerves and the absorption of the bones, is sometimes attended with intolerable pain, capable of being mitigated by no means hitherto discovered. Death at last puts an end to the pain and the patient together; the approach of the fatal event being clearly indicated by the increasing thinness, softness, and darkness of the tumor.

The importance in practice of discriminating between this most dangerous disease and all other tumors is manifest; but the distinction is not always easy, or at any rate is not always made. Many a fatal accident has happened in consequence of incisions having been made into aneurisms which were mistaken for abscesses. Vesalius was consulted about a tumor of the back, which he pronounced to be an aneurism: soon afterwards an imprudent practitioner made an opening in the swelling and the patient bled to death. Ruysch relates that a friend of his opened a tumor near the heel, not suspecting it to be an aneurism, and the hæmorrhage, though suppressed at last, placed the life of the patient in the utmost jeopardy. A person consulted Boerhaave about a swelling at his knee, who cautioned him against allowing it to be opened; it was opened, and the man died on the spot. Even Ferrand, head surgeon of the Hôtel Dieu, mistook an axillary aneurism for an abscess, plunged his bistoury into the swelling and killed the patient. The characters by which the aneurismal swelling may be distinguished from all other diseases are given at great length in surgical books.

There is something in the structure of the larger arteries which predisposes to this disease. Their coats are thinner in relation to the magnitude of the column of blood with which they are filled than the coats of the smaller arteries. The internal are much more subject to aneurism than the external arteries. The curvatures of the arteries are another predisposing cause. The period of life at which aneurism is most frequent is between the ages of thirty and fifty. Sir Astley Cooper, however, states that he has seen the disease in a child only eleven years old, and that he has operated for it with success in a man of eighty-five. It is much more common among males than females. Out of 63 cases of this disease, 56 were males, and only 7 females. Aneurism so often follows a sudden violent shock sustained either by the whole body or by a limb, and more especially by the sudden violent extension of a limb, as apparently to justify the common opinion that external violence is among the most frequent exciting causes of the malady.

Excepting in the exceedingly rare case in which the spontaneous cure, already explained, is effected, this disease, when left to itself, uniformly proves fatal by the ultimate rupture of the tumor, in consequence of which the patient expires either instantaneously from the great and sudden loss of blood, or by degrees from repeated losses of it. And yet anterior to the time of Galen, who lived about the middle of the second century, there is to be found no record whatever of this terrible malady. The older practitioners, indeed, who believed that the arteries were air-tubes, could have had no conception of the existence of an aneurism. It has been justly observed, that were the number of individuals in Europe who are now annually cured of aneurism by the interference of art, to be assumed as the basis of a calculation of the number of persons who must have perished by this disease, from the beginning of the world to the time of Galen, it would help to convey some conception of the extent to which anatomical knowledge is the means of saving human life.

The cure of aneurism consists in the obliteration of the preternatural cavity of the artery. The obliteration of this cavity is the sole object of the operation, which is found to be the only sure and effectual mode of curing the disease. This operation consists in cutting down upon the artery and passing a ligature around it above its dilatation. The immediate effect of the ligature of course is to stop the flow of blood into the sac; its ultimate effect is to excite inflammation in the coats of the vessel, by which its sides, brought into close contact by the ligature, permanently adhere together, thus inducing an obliteration of the cavity of the vessel. The success of the operation depends entirely on

the completeness of the adhesion of the sides of the vessel, and the consequent obliteration of its cavity. But this adhesion will not take place unless the portion of the artery to which the ligature is applied be in a sound state. If it be diseased, as it almost always is, near the seat of the aneurism, when the process is completed by which the ligature is removed [see INFLAMMATION], hæmorrhage takes place, and the patient dies just as if the aneurism had been left to itself. For a long time, surgeons were in the habit of applying the ligature as close as possible to the seat of the aneurism: they laid open the aneurismal sac in its whole extent, and scooped out the blood contained in it. The consequence was that a large deep-seated sore, consisting of parts in an unhealthy state, was formed; and it was necessary to the cure that this sore should suppurate, granulate, and heal,—a process which the constitution was frequently unable to support. Moreover, there was a constant danger that the patient would perish from hæmorrhage, through the want of adhesion of the sides of the artery. The profound knowledge of healthy and of diseased structure, and of the laws of the animal economy by which both are regulated, which John Hunter had acquired from anatomy, suggested to this eminent man a mode of operating, the effect of which, in preserving human life, has placed him high in the rank of the benefactors of his race. This consummate anatomist saw that the reason why death so often followed the common operation, was because a process essential to its success was prevented by the diseased condition of the artery. He observed that while the vessel close to the aneurism was always diseased, at some distance from the aneurism it was in a sound state: it occurred to him, that if the ligature were applied to this distant part, that is, to a sound instead of a diseased portion of the artery, the process necessary to the success of the operation would not be counteracted. But to this there was one capital objection, namely, that it would often be necessary to apply the ligature around the main trunk of an artery, before it gives off its branches, in consequence of which the parts below the ligature would be deprived of their supply of blood, and must therefore mortify. He was well acquainted, however, with that arrangement of the blood vessels which has been explained under the term ANASTOMOSIS. Reflecting on the number and freedom of the communications of the arterial tubes, he conceived it possible that a limb might receive a sufficient supply of blood to maintain its vitality through the medium of its collateral branches only. For an aneurism in the ham, he, therefore, boldly cut down upon the main trunk of the artery which supplies the lower extremity, and applied a ligature around it, where it is seated near the middle of the thigh, in the confident expectation that, though he thus deprived the limb of the supply of blood which it received through its direct channel, it would not perish. His knowledge of the processes of the animal economy led him to expect that the force of the circulation being thus taken off from the aneurismal sac, the progress of the disease would be stopped; that the sac itself, with all its contents, would be absorbed; that by this means the whole tumor would be spontaneously removed, and that an opening into it would be unnecessary. The most complete success followed this noble experiment; and the sensations which this philosopher experienced on witnessing the event constituted an appropriate reward for the application of profound knowledge to the mitigation of human suffering. After Hunter followed Abernethy, who, treading in the footsteps of his master, for an aneurism of the femoral, placed a ligature around the external iliac artery; lately the internal iliac itself has been taken up, and surgeons have tied arteries of such importance, that they have been themselves astonished at the extent of their success. Every individual on whom an operation of this kind has been successfully performed is snatched by it from certain and inevitable death. (See Cooper's *Surgery*; Hodgson on the *Diseases of Arteries and Veins*; Bell's *Surgery*; Abernethy's *Surgical Works*; *Use of the Dead to the Living*, &c., &c.)

ANGEL (COIN.) Dr. Johnson defines it as 'a piece of money anciently coined and impressed with an angel, in memory of an observation of Pope Gregory, that the pagan Angli, or English, were so beautiful, that, if they were Christians, they would be Angeli, or Angels.' But we must remark, that Pope Gregory's observation was made in the seventh century; and the coin called the angel was not struck in England till the middle of the

fifteenth century. The angel was originally a gold coin of France, where it was first coined, at least by that name, in 1340. (See Ducange, *v. Moneta*, and Le Blanc, *Traité Hist. des Monnoyes de France*, 4to. Amst. 1692, p. 207.) In France, where it was soon followed by the half and quarter angel, it was always of fine gold, but not always of the same weight. It appears to have been introduced with its minor divisions, into England, by Edward IV., in 1465, (see Leake, pp. 150–164,) and was continued as a coin by King Henry VI. when he returned to the throne. Angels and half-angels are the only gold coins known of Richard III. (Leake, p. 170.) When first introduced, the angel was rated in value at 6s. 8d., and being of the same value as the noble, was sometimes called the noble angel. This value was continued at Henry VIII.'s first coinage of gold. In the coinage of that king's latter time, the value was raised to 8s., and so continued through the reign of Edward VI. Queen Mary's angel went for 10s., which value continued to the end of the reign of Charles I., the last of our kings who coined the angel. So base was Henry VIII.'s gold coinage of this money, that Stow, in his *History of London*, says, 'I have seen twenty-one shillings given for an old angel to gild withal.' Queen Elizabeth, (according to Nicolson's *Historical Library*, p. 267, from Fynes Moryson's *Itin.* Part i. li. 3 c. 6.) in the 43rd year of her reign, (1600–1601) contracted not only for the coining of angels, and their usual divisions, but for pieces of an *angel and a half* and *three angels*, of the finest angel gold; but it is presumed that the contract for these larger pieces was never completed, as no such coins have been seen by our collectors. The usual device upon the obverse of the angel, was the figure of St. Michael standing upon the dragon, and piercing him through the mouth with a spear, the upper end of which terminated in a cross, or cross-crosslet. The reverse of the earlier ones had a ship, with a large cross for a mast, with the royal arms in front. The angels of James I. and Charles I. have the mast of the ship with a main-top, and no cross. The obverse had the king's titles surrounding the device. The reverse, from Edward IV. to Edward VI., bore the inscription 'PER CRUCEM TVAM SALVA NOS CRISTE REDEMPTOR.' The reverses of the angels of Philip and Mary, Elizabeth, and James I., bore, partly at length, and partly abridged, the sentence, 'A DOMINO FACTUM EST ISTUD ET EST MIRABILE [IN OCULIS NOSTRIS.]' Charles I.'s angel had on the reverse, AMOR POPULI PRÆSIDIVM REGIS. Foikes (pl. xiii. of his *Gold Coins*) has engraved a piece in silver, struck from the reverse only of a die, intended for an angel by King Charles II., but never coined; with the same inscription on the reverse as his father's angel. The only distinction by which the angels of Henry VI. are known from those of Henry VII. is, that in the former, the archangel Michael stands with his left foot upon the dragon; in the latter, the angel stands with both feet upon the dragon. In the collection of Lord Pembroke there is a six-angel piece; but it is not certain that it was intended for a coin. The Angelets of Edward IV., and to Henry VIII., have on the reverse, O CRUX AVE SPES UNICA. The angelets of Edward VI. have the same inscription on the reverse as the angel.

ANGE'LICA, a genus of plants belonging to the natural order *umbellifera*; it comprehends several species, the principal part of which are to be met with in botanic gardens, and one that was formerly very much cultivated as an esculent plant, on account of which we admit the genus here. This, the *Angelica archangelica*, or *Archangelica officinalis*, as it is now sometimes called, is a native of the banks of rivers and of wet ditches in all the northern parts of Europe; in this country it grows abundantly on the banks of the Thames below Woolwich, and in several other places. It is a biennial plant, with a large fleshy aromatic root, blackish externally, but white within; and a stout furrowed branched stem as high as a man. Its leaves are of a clear bright green, shining, and divided into a very large number of heart-shaped finely serrated lobes. The flowers are white, and disposed in round, very compact umbels: they are succeeded by large broad-winged grains of a pale yellowish-brown colour. Each partial umbel is surrounded at its base by seven or eight pointed undivided bractes.

For the sake of its agreeable aromatic odour, this plant has been much cultivated, and is so still on the continent. Its blanched stems, candied with sugar, form a very agreeable sweetmeat, possessing tonic and stomachic qualities. Its roots contain a pungent, aromatic, stimulating principle,

[*Angelica archangelica*, a diminished figure.]

1. A partial umbel of the natural size. 2. A separate flower.
3. The back of one of the partial umbels, showing the bractes.

which has caused them to be employed in scrofulous diseases: they have been administered in the form of infusion and of powder, as diuretics and sudorifics; but in this country they are no longer employed as curative agents.

A very common wild species, the *Angelica sylvestris*, or wild angelica, which is found all over the meadows near the Thames above London, possesses similar properties, but they are weaker, and therefore less important.

ANGELO (BUONAROTTI, MICHEL), the father of epic painting, and scarcely less distinguished as a sculptor and architect, was descended from the noble family of Canossa in Tuscany. He was born in the year 1474, a period peculiarly favourable to genius, when the states of Italy emulated each other in the cultivation of the liberal arts. Michel Angelo, the bent of whose powers manifested itself in his earliest childhood, learned the elements of design in the school of Domenico Ghirlandaio, a celebrated professor in Florence. While he pursued his studies with this master, a seminary was established for the promotion of sculpture by Lorenzo

de' Medici, and Michel Angelo was invited among other youths to study from the collection of antique statues arranged in the Medicean gardens. It is said that the sight of these splendid works determined him to devote himself entirely to sculpture; he began, not merely by copying, but by investigating the principles on which the Greek artists had wrought, and having found a head of a laughing faun, considerably mutilated, he imitated that part of it which was perfect, and restored what was wanting. Lorenzo, who frequently visited the garden, was struck by this demonstration of vigorous capacity; and being pleased no less with the simple manners of the youth, and his evident devotion to his art, he invited him to reside entirely in his house, where he remained three years, treated with paternal kindness, and having the advantage of associating with the first literary characters of the age. At the suggestion of Politian, who also resided with Lorenzo, he executed for this illustrious patron a basso-relievo in marble, the subject of which was the Battle of the Centaurs; he resumed the pencil also during this period, and made many studies from the works of Masaccio. Lorenzo died in 1492. His brother Pietro continued to patronize Michel Angelo, but in a different spirit. Treating art as a toy, he employed him, during a severe winter, to make a statue of snow; and manifesting in all things the same frivolous spirit, he precipitated, by his bad government, the downfall of his family, which was driven from Florence in 1494. On this event, Michel Angelo retired to Bologna, where he contributed two statues to the church of the Dominicans, and after a year's residence in that city, returned to Florence. During this time he made the celebrated statue of a Sleeping Cupid, which was sent to Rome, where it was shown as a piece of sculpture which had been dug up from a vineyard, and was pronounced by various connoisseurs to be a genuine antique, and superior to anything which contemporary art was capable of producing. This statue having been purchased at a high price by the Cardinal S. Giorgio, the trick became known, and Michel Angelo's reputation was so much augmented by it, that the cardinal, though vexed at the deception, invited him to Rome. He devoted himself during this his first residence in the imperial city, to intense study, and executed several works, particularly a Virgin weeping over the dead body of Christ, for St. Peter's church, which excited astonishment, not only by its excellence, but by the apparent facility with which the greatest difficulties of art were surmounted.

Several great works in art having at this time been projected by the government of Florence, Michel Angelo, at the earnest advice of his friends, returned to that city, and the first undertaking on which he exercised his talents was a gigantic statue of David, hewn from a solid block of marble. This work had been commenced some years previously by one Simon da Fiesole, who, finding that he had undertaken a task wholly beyond his capacity, had abandoned it in despair. The misshapen mass which had been thus left, Michel Angelo accommodated to a new design, and produced from it the sublime statue which ornaments the great square at Florence. The Gonfaloniere, Pietro Soderini, was now anxious to enrich the city with some grand production of Michel Angelo's pencil. Leonardo da Vinci had been commissioned to paint an historical picture for one end of the hall of the Ducal palace, and Michel Angelo was engaged to execute another at the opposite extremity. He selected a subject from the wars of Pisa, in which a number of men, while bathing in the Arno, are surprised by a sudden attack on the city, and start up to repulse the enemy. Trumpets are sounding; some of the warriors endeavour, with gestures of furious impatience, to draw their garments over their wet limbs; others rush half-clad into the combat; horse and foot are intermingled, and the whole scene breathes fierceness and slaughter. This cartoon, with the exception of a few dismembered fragments, has perished, but as long as it existed, it was studied by artists from all countries, and Benvenuto Cellini, a scholar and admirer of Michel Angelo, affirms, that he never equalled it in any of his subsequent productions. Michel Angelo had at this time attained only his twenty-ninth year, and had not only established his reputation as the greatest artist of his day, but had created by the novelty and grandeur of his style a new æra in the arts. Julius II., a pontiff who, in the energetic cast of his character, bore a strong resemblance to Michel Angelo himself, having now succeeded to the papal chair, called him immediately to Rome, and commissioned him to make his monument, a

work conceived on a scale which Michel Angelo felt to be commensurate to his powers. He made a design, which, had it been finished according to his original intention, would have surpassed in grandeur, beauty, and richness of ornament every ancient and imperial sepulchre. It was to have had four fronts of marble, embellished with forty statues, besides several mezzos-relievi in bronze. To this design Rome and the world are indebted for the magnificent church of St. Peter's; for Michel Angelo having suggested to the pope that the interior of the old edifice would not allow sufficient space for the monument to be properly seen, the pontiff determined to rebuild the church on a larger scale. While the monument was in progress, the pope delighted to come and inspect it; but the work was interrupted by an accident which strongly marks the character of the artist. Having occasion to make some communication to his holiness, and not having found admission on two applications, in the latter of which he felt himself somewhat superciliously treated by one of the officers in attendance, he gave directions to his servants to sell his goods to the Jews, and immediately set off for Florence. He had scarcely reached Poggibonzi before five couriers had arrived from Julius commanding his immediate return, but Michel Angelo was inflexible, and continued his journey. On arriving at Florence, he set about finishing the cartoon of Pisa, but three briefs were dispatched to Soderini the Gonfaloniere, requiring that he should be sent back. Michel Angelo excused himself, alleging that he had accepted a commission from the Grand Sultan to go to Constantinople for the purpose of building a bridge. The pope, in the mean time, had gone on political affairs to Bologna, and Soderini, fearing he should himself incur the papal displeasure through Michel Angelo's contumacy, persuaded him to go to that city. Immediately on his arrival, and before he had had time to adjust himself, he was conducted by the pope's officers before his holiness, who, looking at him with an angry glance, said, 'What, then! instead of coming to seek us, thou wast determined that we should come to seek thee?' Michel Angelo excused himself, saying, 'that he had quitted Rome, being unable, after his faithful services to his holiness, to endure the indignity of being denied admission to him.' A bishop in attendance, intending to say something in extenuation, observed to the pope, that such persons, however expert in their professions, were usually ignorant of everything else: 'Who told thee to interfere?' exclaimed Julius, bestowing at the same time a hearty blow with his staff on the shoulders of the ecclesiastic; and commanding Michel Angelo to kneel, he gave him his benediction, and received him into full favour, giving him directions at the same time to make his statue in bronze. Michel Angelo soon completed the clay model; the statue was the personification of majesty, but the face had so terrible an expression, that the pope demanded, 'Am I uttering a blessing or a curse?' Michel Angelo replied, 'that he had intended to represent him admonishing the people of Bologna, and inquired if his holiness would have a book placed in one of the hands: 'Give me a sword,' answered the warlike pontiff, 'I know nothing of books.'

On his return to Rome, Julius was induced by the advice of his architect, Bramante, to suspend the execution of the monument, and he gave orders to Michel Angelo to paint the vault of the Sistine Chapel. It is said, that Bramante was instigated by unworthy motives in giving this counsel to the pope, either imagining that the large sums which his holiness was expending in sculpture would leave less at his command for the purposes of architecture; or that Michel Angelo, who preferred the practice of sculpture to that of painting, would incense the Pope by refusing to perform his commission; or finally, that, should he attempt it, he would expose his inferiority as a painter to Raffaele d'Urbino, who was Bramante's nephew. Such are the motives ascribed to Bramante, although, it would appear, on no very rational grounds. If, however, Bramante was really actuated by any unworthy motive, never did an evil intention more completely defeat itself. Michel Angelo, indeed, who was absorbed in the execution of the monument, most earnestly endeavoured to decline the task of painting the chapel, and even alleged that he thought Raffaele better qualified to perform it; but Pope Julius allowed no impediment to stand in the way of his will, and Michel Angelo, finding himself without an alternative, and impressed with a sense of the vastness and grandeur of the task, commenced his cartoons. He invited from Florence several artists distinguished as painters in fresco, a mode of practice in which he was then inexperienced, and the roof of

the chapel was commenced by these assistants, under his direction; their execution, however, fell short of his expectations, and entering the chapel one morning, he dismissed them all, threw their work from the walls, and determined on executing the whole himself. Having advanced to the third compartment, he had the mortification to find his labour frustrated by the bad quality of his materials, in which fermentation had taken place, and in utter disappointment he renounced the undertaking. The pope, being made acquainted with this misfortune, sent to him his architect, San Gallo, who investigated the cause of the failure, and taught him how to correct it. Thus reassured, he proceeded, and the pontiff hearing at length that the ceiling was half completed, could control his impatience no longer, and ordered the chapel to be opened for his inspection. Many other persons found admission, and among the rest Raffaele d'Urbino, who then first became acquainted with Michel Angelo's powers as a painter. Struck with admiration, he immediately changed his own style, and with the candour natural to a great mind, thanked God that he had been born in the same age with so great an artist. The work was now carried forward without interruption, and the whole was completed within one year and eight months from the time of its commencement; an achievement which, whether we consider the magnitude and sublimity of the performance, or the almost incredibly short time in which it was executed, is unparalleled in the history of art. The chapel was opened on All Saints' day, with a solemn mass, at which the pope assisted in person. The roof is divided into twelve compartments, in which is painted the history of the antediluvian world. In three of the first compartments Michel Angelo has personified the Supreme Being, dividing the light from the darkness—creating the sun and moon—and giving life to Adam. The attempt to portray the Deity by visible representation is repugnant to our present ideas, but it was at that time sanctioned by the church, and is almost atoned for by those images of divine power and majesty which Michel Angelo has here embodied. The eleventh subject of the series on the roof is the Deluge, and the twelfth is from the story of Noah, showing the remnant of the human race preserved after that awful event. On the sides of the chapel is a series of designs representing the persons who compose the genealogy of Christ, and between these compartments are the colossal figures of the Prophets and Sibyls, seated in solemn meditation. The effect of the whole work is adapted with admirable accuracy to the vast height at which it is seen, and it is impossible to contemplate it without reverence and astonishment. The reign of Julius terminated in 1513, when Leo X. succeeded.

It might have been expected that Leo X., whose name is associated with the ideas of taste and munificence, and who affected fully to appreciate the powers of Michel Angelo, would have engaged him on some work worthy of his talents. There is, however, in his whole conduct towards this great artist a display of injustice not easily explained. He obtruded on him the task of building the façade of the church of S. Lorenzo at Florence—a commission against which the artist most strenuously protested; but the pope overruled all objections, and compelled him to go to Carrara, in order to excavate marble for the purpose. He was afterwards directed to procure it from the quarries of Pietra Santa: the difficulties of conveying it hence were found almost insurmountable, and we cannot read without surprise and indignation, that during the whole pontificate of Leo, a period of eight years, this extraordinary man was employed in hewing rocks and excavating a road. The short reign of Adrian VI. which followed, although generally unfavourable to the arts, was less injurious to Michel Angelo, as it allowed him leisure to proceed with the monument of Julius II.; but on the accession of Clement VII. that work was again interrupted, and he was called on by the new pontiff to build a library and sacristy for the church of S. Lorenzo. The civil wars of Florence ensued soon after, and we find Michel Angelo acting in the capacity of engineer. On the expulsion of the Medici he was appointed superintendent of the fortifications by the local government, and he evinced extraordinary skill in fortifying the important post of San Miniato. Having continued his services until he felt that they could no longer be effectual, and considering the fall of the city inevitable he withdrew to Venice, and during his residence there, it is affirmed by some authorities, that he gave the design for the bridge of the Rialto.

He returned to Florence at the earnest entreaty of his fellow-citizens, who seemed to attach more importance than himself to his services, but, as he had foreseen, the city was soon after compelled to surrender, and he judged it prudent to conceal himself, as did several of the citizens who had distinguished themselves in its defence. Michel Angelo has been reproached with ingratitude to the Medici for the part he took in those transactions, but he is, perhaps, to be praised rather than condemned for having sacrificed his private feelings to the duty he owed his country. As soon as the tumult consequent on the sack of the city had subsided, Clement VI. ordered strict search to be made for Michel Angelo, received him kindly, consulted him on various works, and the great picture of the Last Judgment was then projected. The death of Clement, in 1533, suspended these intentions, and Michel Angelo now hoped that he should be enabled to complete the monument of Julius II. This work had been the favourite employment of his life, and he had devoted to it all his powers, but it had proved to him, almost from its commencement, a source of inquietude. Each pontiff, since the death of Julius, had on his accession demanded the services of Michel Angelo, and compelled him, in spite of his earnest remonstrances, to discontinue his labours on the monument; in the meantime, the heirs of Julius, being impatient for its completion, harassed him with threats and complaints, large sums of money having been paid him during the progress of the work. Clement VI. insisted that Michel Angelo had a right to consider himself rather the creditor than the debtor; but Paul III., when Michel Angelo urged his obligation to the heirs of Julius, as a reason for declining the commissions he offered him, threatened to tear the contract with his own hands. He came, however, attended by ten cardinals, to see the work which had occasioned so much litigation, and pronounced it to be miraculous. Being shown, at the same time, the cartoons which had been prepared for the Last Judgment, he determined that nothing should impede the immediate execution of that work, and undertook to arbitrate himself between Michel Angelo and the heirs of Julius. The monument was at length finished, by mutual agreement, on a smaller scale than had been originally projected, and placed in the church of San Pietro in Vinculo. Michel Angelo now found himself at liberty to proceed with the picture of the Last Judgment; he devoted to that immense work the labour of eight years, and it was finished in 1541. We are accustomed to connect with this performance an impression of everything which is great in art; nevertheless, whoever expects to find in it that which is usually attached to our ideas of painting, an effect agreeable to the eye, will be utterly disappointed. Art, indeed, was not at that time considered a medium of amusement merely, but a vehicle for religious impressions; and as the leading feeling associated with the awful idea of the last judgment is that of terror, so Michel Angelo has made terror the predominating sentiment of his picture. In the Messiah we see rather the inexorable judge than the merciful Redeemer; he turns to the left, and fulminates his sentence on the wicked, who fall thunder-struck. These groups, precipitated through the air, are seized by demons who spring from the abyss beneath. This is the finest part of the picture, for there is little among the groups of the righteous, who on the opposite side are ascending into heaven, which expresses the happiness of the blessed. That part of the picture in which the dead are seen rising from their graves is admirable. The excellence of the work consists in the unparalleled powers of invention displayed in the various groups, and in the profound knowledge of the human figure by which the artist was enabled so effectually to embody his conceptions; but considering the composition as a whole, it must be acknowledged, that, without impairing the solemn impression proper to the subject, a more picturesque arrangement might have been admitted, and that even the sentiment would have been augmented by more powerful combinations of light and shadow. It was pronounced by contemporary criticism that Michel Angelo had in that work excelled all his former productions; but the deliberate judgment of time, we believe, inclines to decide that his great name as a painter is better sustained by the compartments in the roof, and on the sides of the Sistine chapel, than by the picture of the Last Judgment. The career of Michel Angelo is an example of the splendid results produced by great powers in conjunction with great opportunities. We next find him engaged in constructing the magnificent fabric of St. Peter's church. He

egan by substituting for the Saracenic design of San Gallo, a more Christian and superb model in the shape of a Greek cross. 'This fabric,' to use the language of Fuseli, 'scattered into infinity of jarring parts by his predecessors, he concentrated; suspended the cupola, and to the most complex, gave the air of the most simple of edifices.' On this work he was occupied during the whole remainder of his life. He found opportunities, however, to direct fortifications, to adorn the Capitol with magnificent buildings, to finish the Farnese palace, and give designs for other works of architecture. But circumstances connected with the building of the church embittered his latter years with serious causes of trouble. As he had occasion, among the number of persons employed in the undertaking, to promote some and dismiss others, he was beset by cabals, and harassed by opposition; and machinations were even employed to deprive him of his office: but he was uniformly supported by the pontiffs, especially by Julius III., who regarded him with profound respect and veneration. Old age came upon him not unaccompanied with the physical infirmities which belong to it, but he retained the vigour and alacrity of his mental faculties to the close of his long life. He died on the 17th February, 1563, having nearly attained his 89th year. His last words were, 'In your passage through this life, remember the sufferings of Jesus Christ.' He was buried with due honours in the church of the Apostoli at Rome; but his remains were afterwards removed to the church of Santa Croce, at Florence.

Considered either in relation to the degree or the variety of his talents, Michel Angelo holds a foremost place among the great men of an age which has left the most durable impressions upon the arts and literature of Europe. As a painter and sculptor he created his own style, which, as it owed nothing to his predecessors, so it has remained unapproachable either by rivalry or imitation. As an architect, he converted the fabric of St. Peter's from an incongruous structure into the noblest temple which was ever erected to the honour of the Deity. The few poetic compositions which Michel Angelo has left can add little to his vast reputation, except as an evidence of his versatility; it may be observed, however, that they are by no means unworthy of such a mind, and that, even in point of versification, they rank among the best in Italian literature. His talents in engineering need no other attestation than the fact, that Vauban, the celebrated French engineer, in passing through Florence, was so impressed with the skill evinced in the fortifications of San Miniato, that he ordered plans and models of them to be made for his own especial study. The moral qualities also of Michel Angelo are entitled to our respect. He was benevolent, temperate, and pious; and although he felt the dignity of his own character, and knew how to enforce respect from the arrogant and the supercilious, in his general deportment he was mild and unassuming. He had acquired considerable wealth by the exercise of his various talents, and he employed it liberally; he assisted his friends, provided for his servants, and during the siege of Florence, he supplied the government with sums by no means inconsiderable, considered as the contribution of an individual. For the labour of building St. Peter's church, continued through many years, he refused all remuneration, declaring that he dedicated that service to the glory of God. Although no man was ever more entitled to the claim of intuitive talent than Michel Angelo, no man ever trusted to it less: his practice was incessant, he continued his studies to the last, and so untiring was his energy, that even while engaged in the military operations of Florence, he proceeded with his works in statuary and painting. His predilections were decidedly in favour of sculpture, in preference to the other arts: yet it may be doubted whether his reputation is not more permanently based on his paintings in the Sistine chapel. Beauty, so essential an element in sculpture, was certainly not the branch of art in which he excelled: nevertheless, in subjects wherein that quality is not indispensable, he sometimes reaches a point of unimagined excellence; nor can there be found perhaps, in the whole range of Greek sculpture, any thing approximating to the profound sentiment and terrible energy exhibited in the statues of Lorenzo and of Moses. As a painter, he has no competitor in the highest qualities of art, except Raffaele, to whom, it appears to us, he stands in the same relation which, in our literature, Milton bears to Shakspeare. In depth of pathos, in discriminated expression, in varieties of character, and the power of telling his story, Raffaele is certainly superior to Michel Angelo;

but if the truth of that axiom be admitted, that sublimity, in its highest degree, is more than an equivalent for all other qualities, then is Michel Angelo, without doubt, the greatest painter that ever existed.

ANGELO CARAVAGGIO. [See CARAVAGGIO.]

ANGELN is that part of Schleswig which is enclosed by the bay of Flensburg, the Baltic, and the Schlei. The largest diameter of this district, from N. to S. and from E. to W., is about twenty English miles. Its surface comprehends about 230 square miles, of which the population amounts to 30,000. Among their neighbours the inhabitants are distinguished for bodily strength, an independent spirit, and love of liberty; they are industrious, and in a country where the criminal calendar is insignificant, they contribute towards it the smallest number: in this district prosperity is general. The eastern part of it is very fertile; the western is more sandy: of late great progress has been made in agriculture; but the roads are so indifferent, that they are a subject of general complaint. *Angeln* has not, like other parts of Schleswig, a peculiar political constitution. Fifteen of its northern parishes belong to the *Amt* (the government or county) of *Flensburg*, and the eighteen southern ones to that of *Gottorf*.

ANGER, (according to Aristotle, *Rhetor. b. ii., c. 2.*) is a desire of revenge, accompanied with pain, on account of an apparent slight improperly offered to a person or some one connected with him. From this definition it appears, first, that in order to excite the passion of anger it is necessary that a slight should be offered; and secondly, that the slight produces a desire of revenge, which is painful until it is either gratified or assuaged. A slight is an act or forbearance by which a man appears to indicate his opinion that another person is not worthy of notice; and it may be shown both in active and passive conduct; actively, as when a person insults, reviles, ridicules and banters, or annoys, vexes and teases another: passively, as when a person omits the marks of attention and respect which an inferior owes to a superior, or an equal to an equal, or when he treats another with contempt. In the cases of abuse, insult, and unseemly or misplaced ridicule, as well as where there is a scornful indifference or a want of respectful behaviour, the pain is caused by the undue assumption by which an equal appears to make himself a superior, and an inferior an equal. Hence it is (as an ancient historian has remarked) that men care more for insult than injury; as the one seems to be the aggression of an equal, for his own profit; the other to be the insolence of a superior, arising from spite or mere wantonness*. In the cases of annoyance and vexation, the pain of the person angered is caused by the feeling that the object of the other party is purely to give pain, without any advantage accruing to himself.

The pain excited by the slight is instantly followed by a desire of revenge. The desire of revenge is not a general desire that ill may come to the person offering the slight, but a desire of personally painning him, so that he may know by whom the pain is inflicted, and the person angered may have the gratification of being himself the executioner of his own retribution. The satisfaction of the desire of vengeance is always pleasurable, and in brutal and uncultivated minds is attended with all the marks of the most triumphant exultation. So strong indeed is the temptation of gratifying this craving after retaliation, when the means of indulging it are in our power, and so great the difficulty of foregoing the pleasure which it affords, that Shakspeare enumerates among the rare instances of female perfection—

* She who being angered, her revenge being nigh,
Bids her wrong stop, and her displeasure fly.

No angry person, however, would feel his desire of revenge satisfied by learning that the object of his anger has suffered some grievous calamity, as that he has lost a near relation or a large sum of money: he wishes that the pain should be inflicted *in return* for the slight shown to him, and by *his own* agency. Anger, therefore, is different from hatred; the one is a passion which is commonly extinguished by the lapse of time, even if the desire of vengeance is not satisfied; the other is a settled habit of the mind which never varies: the one is attended with pain, the other is without pain. Anger is always personal, and is felt only towards individuals: hatred is often general, and embraces not only individuals, but whole classes, as murderers, tyrants, heretics &c. There are even national hatreds, and misanthropy

* On a similar reason was founded the advice of Bernadotte to Louis XVIII. that France was to be governed with an iron hand, and a velvet glove: a remark capable of a much wider extension.

is a hatred of the *whole human race*. Anger is often satisfied with a slight infliction of pain, whereas hatred desires nothing less than the extinction of the persons hated; hence pity is consistent with anger, but never with hatred. Anger seeks to inflict pain; hatred desires to do harm. Anger requires a personal retaliation, hatred is pleased that harm should come to the person hated, from whatever quarter, and by whatever means. (See Aristot. *Rhet.*, b. 2. c. 4.)

As anger is a bad passion, the object of which is the infliction of pain, it ought to be restrained; and one of the most important parts of moral discipline is the proper regulation of the desire of revenge which characterises it. The proper government of this passion consists not in altogether suppressing it, which is indeed impossible, as every person must feel pained at an undeserved slight, but in repressing the desire of vengeance to which that pain gives rise. It is a rule, to which every exception should be questioned with the utmost jealousy, that in a political society all vengeance for vengeance sake is immoral. This, however, does not prevent a person from shewing *his displeasure* at an improper slight: so that the reproof be given without animosity, and arise from a desire of preventing future affronts or vexation, not of satiating a thirst for revenge.

Although anger is a bad passion, and in a state of civil society its effects are much oftener hurtful than beneficial, its *use*, (or, as it is sometimes said, its *final cause*) is not the less obvious. In a state of nature, before the institution of government, if instead of men being prompted by the constant and violent influence of a passion to retaliate harm for harm, the retribution of wrongs had been left to the irregular operation of cool reason, it may be doubted whether the collision of interest and the mutual resistance which arose from each man being the avenger of his own cause, and which were the origin of political government, would ever have existed.* Hence revenge (as Lord Bacon has said) is a sort of wild justice; that is, in a society where there is no administration of law, it takes the place of legal justice: and it is better that wrongs should be avenged than that they should be done with entire impunity.† In the barbarous states of society which have prevailed at different times in Arabia, Greece, Germany, Scotland, and other countries, the imperfect security of person which existed was owing chiefly to the duty of revenge imposed by traditional feelings and opinions on the family of a murdered person. But when the exercise of sovereign political power is once firmly established, together with an efficient administration of law by regular judicatories, the use of revenge, as an instrument for the suppression of wrongs, has ceased, and it must give place to a far better substitute. The good, says the French proverb, is the enemy of the better; and on this principle, a political society, both in its legal and moral code, must discard that instrument to which it may, indeed, in great measure, owe its *existence*, but which is incompatible with its *continuance* in a state of happiness and tranquillity. The private retaliation of wrongs is the scaffolding by means of which the structure of civil society was erected, but which disfigures its beauty and impairs its utility when completed. [See PUNISHMENT.]

ANGEBURG, one of the circles of the government of Gumbinnen, in the province of eastern Prussia, containing a surface of 360 square miles, and about 26,000 inhabitants. Angerburg is the name also of a small town, with a castle, lying on the Gross-Mauer Lake, in this province. It makes linens and woollens; has a manufactory of salt, and a fishery; and some trade in timber. The population is about 2900. It is in 54° 8' N. lat., 22° 15' E. long; seventy miles S.E. of Königsberg.

ANGERMANNLAND is a province of Sweden on the Baltic Sea, or rather on that narrow part of it, called the Gulf of Bothnia. It is now comprehended under the political division of Angermanland-Län or Hernösand-Län, of which it forms the northern, most extensive, and important part; the southern, and smaller, is the ancient province of Medelpad. The political union of these provinces obliges us to treat of them together, which may be done the more easily, as they resemble one another in almost every respect.

* It is remarked by Soame Jenyns, that those effects which were required to be constantly produced by mankind, such as the nourishment of the body by eating and drinking, its preservation from physical harm, the propagation of the species, &c., have been entrusted by Providence to our appetites or passions, and never to our reason: the operation of the former being regular and unintermitted, of the latter capricious and uncertain. See the admirable review of his metaphysical work by Dr. Johnson.

† See Bishop Butler's Sermon on Resentment.

Angermanland-Län extends from 62° 10' to 64° 20' N. lat., and from 15° 40' to 19° 20' E. long. Its greatest length lies along the coast, and may amount to between 140 and 150 miles. Its breadth varies from about 20 to 100 miles. On the north it is bounded by Umea-Län or Western Bothnia, on the west by Östersund-Län or Yämtland, on the south by Gefle-Län or Helsingland, and on the east by the Gulf of Bothnia. Its area is calculated to amount to 216 Swedish or 9508 English square miles, so that this province is somewhat larger than the counties of Northumberland, Durham, and York taken together.

The surface of this extensive country varies extremely. On the coast, hills succeed hills without interruption, they are steep and rise sometimes to nearly a thousand feet above the level of the sea. They are divided from one another by steep valleys several hundred feet deep, the bottom of which is occupied by winding rivers, or fine mountain-lakes, on the banks of which meadows and woods are intermingled in the most pleasant manner; the woods commonly clothe the slopes of the hills and sometimes their summits. If to this picture we add the inlets of the sea, which often pass through the narrow openings between the hills, and the large, rapid rivers, expanding at intervals like lakes, we shall acknowledge the justness of the opinion of Dr. Clarke, who compares this province with the country about the Lago Maggiore in Italy, and affirms that all this part of Sweden is as much worth seeing, and would as amply repay the trouble of a journey thither, as any part of Europe. But this description only applies to the coast and to the country extending about twenty or twenty-five miles from it. Farther westward, no insulated mountains are seen, the whole country, for a distance of about ten miles and upwards, rising higher and higher to more than a thousand feet above the level of the sea, and on this height it runs on almost like a plain through Jamtland till it reaches the foot of the Scandinavian mountains, and the boundary of Norway. From these heights the rivers descend in long, and sometimes narrow valleys, and in their descent frequently form cataracts.

The coast of this country, though high, rarely rises to 200 feet, and is very much intersected by bays, some of which run several miles into the land, especially Hämmarsunds-Fiard, Deger-Fiard, and Ullangers-Fiard, all three situated to the north of the mouth of the Angerman-Elf. An uninterrupted series of islands extends along the coast: most of which are small, uninhabited rocks, called *skär* (pronounced *share*), only visited in summer by fishermen. Some, however, are several miles in length, as Bröman, to the south of the mouth of the Ljungan-Elf, Alnön, opposite to the Sundswall, and Hernö and Hamsö, in the embouchure of the Angerman-Elf.

The rivers which traverse Angermanland-Län are the largest in Sweden, but they do not rise in the province. Their sources are in the Scandinavian mountains, to which this province does not extend. The most important is the Angerman-Elf, which rises in an alpine lake, called Kult-Tön, near the boundary of Norway, in that part of Umea-Län called Asele Lapmark. Running for nearly half its course in a south-eastern direction, it receives all the waters descending from the Styelling Föttl, and the great chain in Asele Lapmark; it then enters, by a southern course, Angermanland, where its waters are increased by two large rivers, coming down from Jamtland. Its general course is still directed to the south or south-south-east. No river of Sweden is, in its natural state, navigable, so far as the Angerman-Elf. It may be ascended by vessels of every description upwards of forty-five miles, and by merchant-vessels to Sollefteå, nearly sixty miles. At the last place navigation is interrupted by a cataract, and higher up, other water-falls likewise impede the transport of goods. But in late years, the Swedish government has paid much attention to rendering it navigable. Not far from its mouth Dr. Clarke found the breadth of the river from one end to the other to be two miles, and he adds, that the Rhine exhibits not a grander, and that the banks of the latter are at no more beautifully adorned, than those of the Angerman-Elf. The whole course of the river amounts to upward of 100 miles. The Indals-Elf, which traverses the southern part of Angermanland-Län, or Medelpad, is properly the channel by which the lake called Storsjön (the great lake) discharges its waters. This lake is situated in a country surrounded by an elevated country, which exhibits even snow-covered mountains on the west and south.

these mountains numerous rapid rivers descend to the lake, which discharges these collected waters by one outlet, the river Indals-Elf. It issues from the lake on its northern side, and flows for some distance to the north; it then turns to the east, and descends from the high-lands to the coast, and in this descent still receives some considerable rivers. The latter part of its course is to the south-east. It is one of the swiftest rivers of Sweden, full of rapids and cataracts, and only navigable for boats and craft, for a short distance. Its inundations are much dreaded; one of them, in 1796, laid waste all the valleys through which it flows, and changed the course of the river in many places. Since that time its water has been turbid, and the salmon and other fish, which formerly abounded, have left it; only a kind of whiting (*salmo lavaretus*) is occasionally taken. It runs about 140 miles. The third and most southern river is the Ljungan-Elf. It rises in that part of Osternsunds-Lan which bears the name of Heryedalen, in the most elevated part of the Scandinavian peninsula, from which it descends with a rapid course through a narrow valley; but as it approaches the boundary of Angermanland-Lan the valley widens and the course of the river becomes less rapid. After its entry into this province it receives its only great tributary, the Giman, and falls into the sea to the south of Sundswall. Twenty years ago this river was not navigable; but since the cession of Finland to Russia it has been rendered navigable in many parts of its course in order that Stockholm may not be under the necessity of deriving its firewood from a foreign country. By examination it was ascertained that two-thirds of this river may be rendered fit at least for floating down the wood and timber which abound on its banks. Its course can hardly be less than 200 miles.

The lakes though small are very numerous, and, according to the calculation of Forsell in his statistical tables, occupy more than one-tenth of the whole surface, or, more exactly, 22·22 Swedish or 977·68 English square miles.

The climate, though very healthy, is also very severe, as might be expected in such a latitude. The winter commonly lasts seven or even eight months, and people often travel in sledges in May. Then follows a spring of two or three weeks, and the summer begins in the middle of June. The heat increases rapidly, and the vegetation is so vigorous, that in a couple of days the grass attains the length of a finger, and commonly more; rarely eleven or twelve weeks pass between the sowing and the reaping of the corn. The sky is generally serene and clear, and rain is not frequent, and very rarely continues half a day. But the valleys are covered in the morning by a dense fog, rising from the lakes and rivers, which imparts the necessary moisture to the fields, and hinders the night frosts in August and September from damaging the crop. The summer ends in the beginning of September, a short autumn follows, rarely longer than the spring, and then comes the winter with all its severity.

Travellers commonly speak with rapture of the fertility of this province, and assert that it surpasses all the other parts of Sweden. But this remark can only apply to tracts of very small extent, especially to the valleys along the large rivers, and to the low land about the lakes. By far the greatest part is sterile; and all the broad and long ridges of the high country contribute little or nothing to the maintenance of the inhabitants. In Forsell's table the arable land is calculated to occupy only 1·28 Swedish, or little more than 56 English square miles, consequently not much more than one-fourth of the surface of the smallest of our counties, Rutlandshire. The meadows extend over a space equal to 6·40 Swedish, or 281 English square miles, nearly the extent of Middlesex. The remainder is covered with mountains, heath, and forests, which only furnish abundant pasture in summer.

Bears, wolves, and foxes, are numerous, but the two former only in those parts which are distant from the coast. Deer was formerly found in greater numbers, but has much decreased, except roe-deer, which is still frequent in many parts. The elk is only met with in some forests of Medelpad. The smaller animals whose skin is used as fur, as hermelins, martens, &c., are found everywhere, but not in any great numbers.

Blackbirds of a large size, woodcocks, heathcocks, and partridges exist in the forests in such numbers, as can hardly be conceived. Many thousands are annually killed, and brought in winter to Stockholm and even to Gothen-

burg, from which latter place some are brought to England. Eagles of considerable size inhabit the solitary places.

Fish abound in the sea, the rivers, and the lakes. The sea-fishery affords a livelihood to many families by the immense number of strömlings, a smaller kind of herrings, which in summer-time are caught along the coast. This fish is found along the whole eastern coast of Sweden, but is nowhere so numerous as here, which brings the fishermen from more southern places, especially from Getle, to pass the summer on the islands along the coast. The produce of this fishery is not exported, but it forms an important branch of internal commerce. In the rivers the salmon-fishery is important, especially in the Angerman-Elf and Ljungan-Elf; trout also abound in some of them.

The forests which cover the greatest part of the country, the upper part of the slopes, and even sometimes the tops of the hills and mountains, consist chiefly of pine, fir, and birch. The oak does not succeed, on account of the severity and length of the winters. These forests not only afford the necessary firewood to the inhabitants, but also some articles of exportation. In some of the higher parts of the country, where the crops are scanty and subject to be destroyed by the early night-frost in September, the inner bark of the pine is mingled with flour in making bread.

The metallic riches of this province are not important. Iron, indeed, is found in some places towards the boundary of Jamtland, but is not much worked.

Fruit-trees do not succeed to the north of 62° 30', and the last apple-trees which produce ripe fruits grow at Sundswall. At Hernösand apple-trees are planted, but the fruit does not ripen. Nature, however, has supplied this deficiency by numerous kinds of wild-growing berries. Besides different sorts of vaccinium and rubus, which are common in some other parts of Europe, there are two species of delicious berries, which are peculiar to the north of Sweden, the *rubus arcticus*, and the *rubus chamaemorus*, or cranberry, of which the first is by far the more delicate, and very extensively used: all trials to transplant it to the south of 62° have been unavailing. Cranberries are exported to England.

Though only a very small portion of the whole surface is allotted to agriculture, it cannot be said that this most important branch of industry is neglected; not only are the fields cultivated with great care and attention, but continual efforts are made to extend the dominion of agriculture more and more. The inducement is great, as the produce of agriculture is by no means sufficient for home consumption, and a considerable quantity of corn is imported from Wasa and other towns of Finland. Rye, barley, and oats succeed pretty well, whenever they are not destroyed by early night-frost. Wheat does not succeed every year, and therefore its culture has been almost entirely abandoned. The culture of flax and potatoes is extensive, though the former does not ripen to seed. Hemp is, likewise, cultivated. The kitchen-gardens are commonly only planted with cabbages and turnips.

The uncultivated ground in the woods, and on the long and broad backs of the mountains, affords pasture in abundance, and, consequently, the rearing of cattle is an important branch of industry. But as these pastures are very distant from the villages to which they belong, a custom has been introduced which also prevails in the Alps of Switzerland; the cattle are sent in June to the pasture, accompanied only by one or two girls, who pass the whole summer in a cottage rudely constructed of wood and branches of trees, take care of the cattle, defend it from the bears, and perform the labours of the dairy. As the summer pasture is so abundant, the inhabitants are much more intent on extending their meadows than their corn-fields: that they may be able to increase their stock of cattle, and not want the necessary fodder for the winter. Many persons, therefore, who are obliged to buy corn, bring considerable quantities of butter to the market, and even some cheese of indifferent quality. Their cattle is of a middling, or rather small size, but well adapted for their pasture. Horses are bred in numbers; they are also of a middling size, but larger than those of the southern provinces of Sweden, swift and hardy. Sheep too are numerous, but the wool is coarse, and only employed by the country people for their own use. The pig is not much attended to, because this animal encroaches on the food of man, which here is rather scarce. In many places in the higher valleys goats are kept in great numbers.

The scanty population of this country might lead us to suppose that no kind of manufacturing industry could be maintained, but this is not the case. The manufacture of linen is very extensive. Great quantities of it are made, especially in the country along the coast to the north of Hernösand. The finer sorts are said not to be inferior to those of Holland, but many think that this assertion is somewhat too favourable to the Swedish peasant women who make it. At all events, the manufacture is considerable, as in the year 1825 not less than 595,870 ells (of nearly two English feet) were exported to Stockholm. The legislature of Sweden has encouraged this branch of industry by premiums, and since that time not only all the flax grown in the province, but also a considerable quantity brought from Russia, is worked up. No other branch of manufacturing industry is carried to any extent, because the peasants, living at great distances from one another, have been accustomed to satisfy all their necessities by their own labour.

Since government has rendered the rivers more navigable than they were twenty years ago, great quantities of timber are floated down the Angerman-Elf and the Ljungan-Elf. The timber is sawed and sent to England. The exportation in 1825 amounted to 16,379 dozen planks and boards, and since that period it has much increased. Tar is also made, but much less than in the more northern province of Umea-Län.

The coasting trade to and from Stockholm, and some places in Finnland, gives occupation to some people who live in the lower valley of the Angerman-Elf.

To maintain internal commerce, some annual fairs are established in the more inland parts of the country. That of Sollefå, up to which place the Angerman-Elf is navigable for merchant-vessels, as we have already observed, is known over all the north of Sweden, and visited by Laplanders, Norwegians, and even by merchants of Stockholm. Here are sold horses, fish, butter, hides, tallow, rein-deer, meat, &c., to a large amount. Another fair is held at Hammar, likewise on the banks of the Angerman-Elf, but it is not so considerable; planks and boards, and coarse linen, are the chief articles sold here. But such fairs are a poor substitute for a town, well provided with shops and every kind of merchandise. This has induced some peasants to become travelling merchants, and these people go on business as far as Stockholm and Drontheim in Norway, whence they import many fine horses.

The two towns of Angermanland-Län are Hernösand and Sundswall. The former, the capital of the province, and the seat of the provincial government, is situated on the island of Hernö, at the mouth of the Angerman-Elf, and joined to the continent by a bridge. The bays between the island and the continent form the spacious harbour of the town, which itself consists of well-looking houses, mostly built of wood. Its streets are large, and, for the most part, paved. The principal articles shipped here are planks and deals, and the linen made by the country people. The first go to England, the latter to Stockholm. But the greatest part of the inhabitants, whose number in 1825 amounted only to 1840, gain their livelihood by the fishery of the strömlings. A few vessels are built. This town has an excellent grammar-school, a society for the improvement of agriculture, an hospital, and a poor-house.

Sundswall is situated in the southern part of Angermanland-Län, or in Medelpad, in a very fine, pleasant valley, much admired by Dr. Clarke and other travellers, and on a bay, into which the Ljungan-Elf discharges its waters, opposite the island of Alnön. The houses are neat, though mostly of wood, but the streets not paved. It has some commerce, especially in planks and deals; but the greater part of the inhabitants, who, in 1825, amounted to upwards of 1600, are engaged in the fishery of the strömling.

At Wifsta, a small place, with a good and safe harbour, five miles to the north of Sundswall, a few vessels are built. There are besides two other places, from which great quantities of planks are shipped, Nyland, on the Angerman-Elf, about twenty-four miles from its mouth, and Swartwick, at the embouchure of the Ljungan-Elf. The property of the latter harbour has been acquired by an English mercantile house, Peter Dixon and Company.

The whole population of this country was, about the middle of the last century, estimated at about 42,000; but the census of 1825 gives it 72,237; and for the year 1830, it was calculated by Forsell, to amount to 78,821; so that every English

square mile, at present, is inhabited by only eight or nine persons. The inhabitants are nearly all of Swedish origin. A few Finlanders, who settled among them two centuries ago, have lost their peculiar habits and customs, and nearly their language. The Laplanders, and their herds of rein-deer, pass the winter in the higher parts of the province, but in the summer they leave it, and go to the mountains. No part of this country rises to 2200 feet above the level of the sea, which, according to Von Buch, is the height on which these animals find, in summer, the climate and pasture adapted to them.

The inhabitants of Angermanland are of a middling size, and do not attain the large stature of the Dalecarlians; but they are stout, vigorous, and, at the same time, quick in their motions and work. They are gifted with great talent, and show it in some arts, especially in architecture and carving. Many churches are built by simple peasants, and the rules of acoustics exactly observed. Their manners are frank, courteous, and graceful, more than those of the other inhabitants of Sweden. They are of a cheerful temper, good-natured, and hospitable. Their houses have the appearance of neatness and prosperity, and this appearance is by no means fallacious; for the people are actually more prosperous and wealthy than other Swedes, inasmuch as they are also more laborious and industrious.

The town of Hernösand is the seat of a bishop, whose diocese extends over the whole north of Sweden: besides Hernösands-Län, he has the inspection of the clergy in Östersunds-Län, Umea-Län, and Pitea-Län.

(See Von Buch's *Travels through Norway and Lapland*; Dr. Clarke's *Travels in various parts of Europe, Asia, and Africa*; Schubert's *Travels through Sweden, Lapland, Norway, Finnland, and Ingermanland*; and Forsell's *Statistical Tables*; *Map of Forsell*.)

ANGERMUENDE, a circle in the Prussian province of Brandenburg, containing 25,000 inhabitants. Also the capital of the preceding circle, built on the shore of a small lake; it has a population of 3000 souls, produces woollens and linens, and raises some tobacco: it lies forty miles north of Berlin.

ANGERS, an important town in France, in the department of Maine and Loire, of which it is the capital now, as it once was of the province of Anjou. It is on the banks of the Mayenne, (chiefly on a gentle declivity rising from the east or left bank,) a little below its junction with the Sarthe, and a very few miles above its influx into the Loire. In the ancient parts of the town the streets are narrow, and many of the houses are built of wood, though in some the wood is concealed by a thin covering of slate; several have open galleries in front and deep projecting roofs, which appear calculated to afford the shelter required by the climate: the galleries are light and carved in stone, and the vine, which grows luxuriantly in the district, is frequently seen entwined round their Gothic mouldings, or running across the street from house to house. The more modern quarters are regularly and well built. Among the principal edifices are the castle and the cathedral. The former on a steep rock, at the base of which the Mayenne flows, has walls of great height and thickness, flanked by eighteen massive circular towers, the work of early ages; the chapel and palace within the castle, built by René of Anjou, in the fifteenth century, are of much later date than the rest of the building. It is defended on the side of the town by a deep moat. The town itself is surrounded by ancient and extensive walls, of dark brown stone, and strengthened by towers. The cathedral, dedicated to St. Maurice, stands on an eminence in the centre of the town; it has two lofty spires. The architecture of the interior exhibits exquisite work, and there is fine painted glass and tapestry of great antiquity. The tomb which contained the remains of René, king of Sicily (above mentioned), and of his daughter, Margaret of Anjou, queen of our Henry VI., was destroyed at the revolution, during which many convents (they were numerous in Angers) were destroyed, the ruins of which still remain. There are the fragments of a Gothic bridge over the Mayenne, which once served to connect the town with some fortifications on the opposite bank; and a church, remarkable for its curious and ancient architecture, is in the state in which it was left by our King John, who committed great devastation in this place. There are several public walks, as the 'Turcie,' the 'Champ de Mars,' and 'Le Bout du Monde, (the world's end.) &c.

The manufactures of Angers are of sail-cloth, camblet

serge, handkerchiefs, hosiery, &c.; and there are establishments for bleaching wax, and refining sugar. Besides the articles from their own factories, the inhabitants carry on a trade in the agricultural produce of the surrounding district, corn, wine and brandy, flax, hemp, wax, honey, and dried fruits. In the neighbourhood are extensive slate-quarries, which give employment to 3000 workmen, and furnish annually 80,000,000 slates. The population of the town is about 30,000, which is rather less than that given in the *Encyclopédie Méthodique*, (Paris, 1782,) viz., 34,000, showing a diminution within the last half century. In 1670, before the revocation of the edict of Nantes, it is said to have been 50,000.

Angers is the see of a bishop, and the seat of a '*cour royale*' (assize court). It has an '*académie*,'* '*collège royal*,' (high school,) a school for the deaf and dumb, and a '*séminaire*,' (place of education for the priesthood,) a public library of 26,000 volumes, a museum of natural history, a fine collection of French paintings, a botanic garden, an agricultural society, and a royal school of arts and trades. The hospital of St. John, said to have been erected by our Henry II., has an extensive Gothic hall, used as a chamber for the sick, of great width and height, with a double row of light columns supporting the roof. There are two theatres.

The traveller Bernier, and the poet and philologist Menage, were natives of Angers. In the time of its subjection to the Romans, the town was called Juliomagus and subsequently Andecavi. It is 178 miles S.W. of Paris; latitude 47° 28' N., longitude 0° 33' W.

The arrondissement of Angers contains 59 communes and 92,810 inhabitants. Its extent is equal to 436 square miles, or 279,040 acres.

ANGERSTEIN GALLERY. [See NATIONAL GALLERY.]

ANGINA PECTORIS, literally, 'a contraction or tightening of the chest,' a disease so named from the anguish felt in the chest. This disease is characterized by a sudden attack of severe pain in the lower part of the chest, commonly inclining to the left side; the pain is sometimes so severe, that the patient feels as though he must die: the pain generally extends to the left arm, and occasionally also to the right; it is often attended with a sensation of fainting or of suffocation, and with palpitation of the heart, but frequently these latter symptoms are absent; the pulse is commonly quick, weak, irregular, or intermittent, though sometimes it is little affected; the countenance is commonly pallid, and the expression anxious and depressed. This attack comes on in paroxysms, which last from a few minutes to half an hour and more. There is no regular interval between the paroxysms, and no distinct warning of their return. They usually come quite suddenly, from slight causes, and often when no cause can be assigned. The health at first is tolerably good during the intervals, but in the progress of the disease a great variety of uneasy sensations distress the patient even when the paroxysm is absent, chiefly those which indicate a disordered state of the digestive and respiratory organs.

Much investigation has been instituted to ascertain the seat and nature of this disease; and although physicians are not yet unanimous in their opinion in regard to either, yet sufficient evidence has been accumulated to determine both with a high degree of probability. It seems upon the whole to be established that it is primitively a nervous affection, and that the nerves in fault are those which supply the lungs and heart—the lungs in consequence of the disease of its nerves being unable perfectly to decarbonize the blood, and the heart, in consequence of the disease of its nerves, not being duly nourished, and consequently not being able to carry on the circulation with the requisite energy and regularity. On inspection of the organs after death of those who perish by this disease, in the immense majority of cases appreciable disease is discoverable both in the lungs and in the heart, but more especially in the latter. The most frequent morbid appearances in the heart are ossification of the coronary arteries (the nutrient arteries of the organ); ossification of the valves of the heart; preternatural accumulation of fat on its external surface; enlargement of its cavities; and, above all, change of structure in its muscular substance, which becomes pallid, soft, flabby,

thin, and easily torn. This change in the muscular substance of the heart is by far the most constant morbid appearance; but even this, as well as the other organic changes, must be considered as the effect rather than the cause of the disease, in whatever degree these organic changes may be the cause of death.

Angina pectoris is most frequent at the meridian of life and beyond it; it may occur in adolescence, but it is very rare at that period. It is much more frequent in the male than in the female. Out of one hundred cases, seventy were upwards of fifty years of age, and seventy-nine were males. It is remarkably under the influence of mental causes, if it be not in the first instance induced by them. When it has once occurred, a paroxysm is readily produced by any emotion, whether of a pleasurable or a painful nature, but more especially by the latter. Anxiety of mind, any depressing passion, or anger, places a person subject to this disease in the most imminent danger. Many persons have died suddenly, instantaneously, under the influence of such emotions. There is conceived to be a close connexion between this disease and gout. Without doubt it is very often found in persons who are subject to gout, and the less the gout affects the extremities, in its regular and decided form, the more frequently and severely such persons suffer from angina pectoris.

It is of the nature of this disease to proceed progressively from bad to worse. At first it is a temporary evil of short duration, recurring, perhaps, only at distant intervals; but if it be neglected, the intervals become shorter and shorter, and the paroxysms more and more severe. Complete success often attends the early, active, and judicious treatment of it. This, therefore, is eminently one of those diseases, the first accession of which should excite serious alarm, and induce every one to adopt without delay, and with the greatest regularity, the means best fitted to prevent the recurrence of it.

Those means are, in the paroxysm, absolute rest. The paroxysm often comes on in walking or during some bodily exertion: the patient has the feeling that the continuance of such exertion would prove instantaneously fatal; and it is really highly dangerous. Unless in very severe cases, the paroxysm usually goes off spontaneously, in a few minutes, on sitting perfectly still, or, which is often better, on lying down. If the pain do not quietly subside, vigorous friction with a stimulating liniment should be applied over the whole chest, and the patient should instantly take some warm antispasmodic and stimulant medicine, such as two ounces of the camphor julep, with a dram of ether or of the aromatic spirit of ammonia. But much more active measures may be necessary; and this is a disease so serious in its nature, and requiring so much delicacy and skill in the management of it, that the patient ought to place himself under the best medical guidance he can procure as quickly as possible. It is during the interval that the most effectual treatment must be employed. It is impossible to discuss here the remedies which the physician should resort to, the reasons which should determine his choice, and the different states which should modify the treatment in adaptation to individual cases. But it is very important to state, that angina pectoris is one of those diseases in which the concurrence of the patient with the efforts of the physician is indispensable. Unless the patient resolve and firmly adhere to his resolution strictly to conform to the plan prescribed in diet, in exercise, in every locomotive movement, in sleep, temperature, and medicine, but above all in the regulation of the mind, the physician can do but very little for him.

ANGIOSPERMIA. [See DIDYNAMIA.]

ANGLE OF CONTINGENCE, or CONTACT, the opening made by a curve and its tangent. [See CURVATURE.]

ANGLE (CURVILINEAR), the rectilinear angle made by the tangents of two curves at the point where they meet, as ABC.

* Although there is only one institution in France designated 'university,' yet that term will convey to the English reader the best idea of what the French term an '*académie*.'

ANGLE (HORARY), the angle formed with the meridian of any place by a great circle, which passes through a star and the pole.

ANGLE OF INCIDENCE, REFLECTION, REFRACTION, ELONGATION, ELEVATION, THE VERTICAL.—see these several terms.

ANGLE, PLANE, SPHERICAL, SOLID, PARALLACTIC.—see these terms.

ANGLE OF POSITION, usually the curvilinear angle made by two great circles drawn through a star to the poles of the ecliptic and equator. It may be used to signify the angle made by lines drawn from any point under consideration to any two points which are used in determining the position of others.

ANGLE (RECTILINEAR), from the Latin word *angulus*, of the same signification. The notion (for it can hardly be called definition) is the *opening* made by two straight lines which cut one another. The term *inclination* is also used synonymously with angle; thus, the angle or opening of two lines is called their inclination to one another.

To investigate a more precise definition for this word, we must recollect that any species of relation is entitled to the term *magnitude*, and becomes the object of arithmetic or geometry, so soon as it can be shown that the notion implied in one or other of the words equal, greater, or less, is always derivable from the consideration of two such relations. Take the two angles or openings made at the points A and B by the straight lines AP and AQ at A, and by BR and BS at B, and transfer the first figure to the second, so that the point A shall fall upon B, and the straight line AQ upon BS; or rather, let as much of AQ as is equal to BS fall upon BS, and let the remainder of AQ form a continuation of BS: also let AP and BR be made to lie upon the same

side of BS. We have now no longer any control over the position of A P with respect to A Q, since the first figure is not to undergo any change except that of simple removal into another position. If, after AQ has been placed upon BS, AP then fall upon BR, the two openings or angles at A and B are the same. If A P, in its new position, fall between BS and BR, the opening or angle at A is less than that at B; and if A P fall further from BS than BR does, the angle at A is greater than that at B. The angle at A is called the angle PAQ, and that at B, the angle RBS. Hence the notion of one angle being twice or three times, &c., as great as another may be fixed.—For example, the angle

MAP being made up of the two MAN and NAP, each of which is equal to the angle DBC, is twice DBC; the angle QAM is three times DBC; RAM is four times DBC: and so on. Similarly, the angle DBC is one-half of PAM, one-third of QAM, &c. The angle made by two lines does not depend upon the length of these lines; if a part DE be cut off from BD, the angle is not altered, that is, the angle EBC is the same as DBC. If Be and Bd be respectively equal to BE and BD, and if BCed turn round B, the same *quantity of turning* which brings Be into the position BE, will bring Bd into that of BD.

When we cast our eyes on two angles, the sides containing which are nearly equal in both, we judge of their comparative magnitude by the spaces which are included between the lines. But this is not a notion capable of being rendered rigorous, because one boundary of the space is indefinite. Nevertheless we may correct this method of judging, and produce a precise idea of an angle, if we admit the propriety of comparing with one another spaces which are absolutely infinite in extent. The longer the lines are, the more nearly is the preceding notion absolutely correct, because the space

at and near the mouth of the angle; which for want of a definite boundary is doubtful as to whether it is or is not to be considered a part of the angular opening, becomes less and less with respect to that about which there is no doubt. If then we suppose the lines which contain the angle to be produced without end, the infinite spaces so imagined will be correctly in the same proportion to one another as the angles. The objection to introducing this into geometry is the real or supposed want of rigour in the comparison of unbounded spaces. [See INFINITE.] It must be remarked, however, that the disputed theory of parallels follows immediately and rigorously from the preceding, (see *Library of Useful Knowledge, Study of Mathematics*, pp. 77, 78; and Lacroix, *Eléments de Géométrie*, p. 23, note,) and it is therefore in the choice of every person to decide for himself whether he will add the words in italics to the first of the two following axioms, and *prove* the second, or *omit* the words in italics, and *assume* the second.

1. Two spaces, *whether of finite or infinite extent*, are equal when the one can be placed upon the other, so that the two shall coincide in all their parts.

2. Through a given point, not more than one parallel can be drawn to a given straight line.

In order to bound the preceding spaces, and compare angles by means of spaces or lines, it is necessary to draw arcs of circles having equal radii through the two points.

Let PQ and RS be arcs of circles having the equal radii

AQ, BS. Then the angles PAQ and RBS are in the same proportion as the spaces (called *sectors*) PAQ, and RBS, and also as the lengths of the arcs PQ and RS. This proposition, which is Euclid, vi. 33, is not so far from first principles as its position would appear to indicate. For the fifth book, on proportion, is entirely independent of, and might be considered as antecedent to, the first four books; if this were supposed, the preceding proposition might be easily made to follow book i. 23, or even i. 8. We might even place it immediately after the doctrine of proportion, by a proof founded on simple superposition, provided we assume (what is tacitly assumed in various parts of the first book of the elements, i. 4, for example) that an angle may be conceived equal to another angle before we know how to construct equal angles.

If a line setting out from A be conceived to revolve round the point A, it will in every position form two openings or angles with its original position AB. For example, in the position AC, AB and AC will form the smaller angle BAC, and the larger angle made up of the angles CAF, FAK, and KAB. Only the former of these is usually considered in geometry, but the latter is frequently used in analysis. When half a revolution has been made, and AB has come to AF, at first sight we might say there was no angle formed; but on looking at the preceding position AE, we see that the opening of BA and AF is greater than that of BA and AE. The half of this opening BAF, that is, BAD, is called a right angle. A whole revolution makes AB pass through four right angles, and, in analysis, if we wish to point out that the line AC is supposed to have made a complete revolution, and to have come into the position BAC for the second time, the angle made with AB is said to be 4 right angles + BAC.

An angle is said to be *obtuse* when it is greater than a right angle, and less than two, and *acute* when it is less than one right angle.

For the most important properties of angles see TRIANGLE, PARALLEL, POLYGON, TRIGONOMETRY.

The methods of measuring an angle, of which we think

necessary to take notice, are three in number. The first is the one universally employed in *theoretical* investigations, and is as follows:—in the last figure but one, the number which expresses what proportion the arc P Q is of the radius, is the number chosen to represent the angle. It is shown in geometry that if any number of arcs be drawn with the centre A, subtending the same angle P A Q, what part soever any one of them is of its radius, the same part is any other of its radius. That is, whatever circle may be chosen, the preceding measure gives the same number for the same angle. For example, if the arc P Q be equal to the radius, the angle P A Q is the angle 1. If P Q be two-thirds of the radius the angle P A Q is the angle $\frac{2}{3}$. The unit of this measure is therefore the angle whose arc is equal in length to its radius. It is customary to say that an angle or arc (for the terms are frequently confounded) thus measured, is given in parts of the radius: but this expression does not convey much meaning, and we cannot propose any better, unless it might be judged proper to say it is measured in *theoretical* units, meaning thereby in the units which are always employed in pure theory. The *theoretical* unit would then be the angle subtended by the arc which is equal to its radius.

The semi-circumference of a circle contains its radius

3'14159, 26535, 89793, 23846

times, very nearly. This is then the number of theoretical units contained in two right angles. The right angle is therefore

1'57079, 63267, 94896, 61923

and the following are the angles of one degree, one minute and one second, to which we shall presently come:

·01745, 32925, 19943, 29577 degree
·00029, 08882, 08665, 72160 minute
·00000, 48481, 36811, 09536 second.

In the second measure, in which angles are said to be measured in *space*, (the word *space* being here opposed to *time*, as we shall see, and not to *length*), the whole angle traced out in one revolution, equal to four right angles, is divided into 360 equal parts, each of which is called one *degree* and marked thus (°). Each degree is divided into 60 equal parts, each called one *minute* (′), and each minute into 60 equal parts, each called one *second* (″). Formerly, the second was divided into 60 equal parts called *thirds*, and so on, but it is now usual to use the tenths, hundredths, &c., of seconds. The present table therefore stands thus:

A whole revolution = $360^\circ = 21600' = 1296,000''$
A right angle = $90^\circ = 5400' = 324,000''$

Degrees.	Minutes.	Seconds.
1	60	3600
	1	60

To convert an angle from *theoretical units* into *degrees &c. of space*, observe that the last mentioned unit is

206264''·806247096355 in seconds
3437'·746770784939 in minutes
57°·295779513082 in degrees

and multiply the number which expresses the angle in theoretical units by the one among the preceding numbers which has the same denomination as that to which the angle is to be reduced. As many decimals may be taken as shall be considered necessary. The following table, however, will be found more convenient.

Degrees.	Minutes.	Seconds.
1	·05729578	·03437747
2	·11459156	·06875494
3	·17188734	·10313240
4	·22918312	·13750987
5	·28647890	·17188734
6	·34377468	·20626481
7	·40107046	·24064227
8	·45836624	·27501974
9	·51566202	·30939721

EXAMPLE. What number of minutes and decimals of minutes does the angle contain which expressed in theoretical units is 1'7906?

From the minutes column take out the rows opposite to 7, 9, and 6; write them so that the first figure of each shall fall under its corresponding figure in 1'7906, and add, but take only so many out of each row as will serve to fill up the places under the first row, increasing the last figure

of each broken row by 1, when the first neglected figure is 5 or upwards.

·7906

03437747
2406423
309397
2063

06155630

Place the decimal point *three* places off the unit's column for *degrees*, *five* for *minutes*, and *seven* for *seconds*. This gives 6155'·630, since the present calculation is made for minutes. Further to illustrate the placing of the decimal point, let the angle theoretically expressed be ·096, to be turned into degrees and decimals of degrees, and afterwards to seconds and decimals of seconds.

0· 096
.....51566202
.....3437747

0 055003949

Bring down the preliminary ciphers, and then cut off three places, which gives 5°·5003949. Again, for the seconds

0· 096
.....185638325
.....12375882

0 0198014213

Cut off *seven* places, which gives 19801''·4213

Given an arc of a circle and the radius to determine the degrees, minutes, or seconds in the angle at the centre, divide the arc by the radius, and proceed with the quotient as above.

For the converse problem, given the degrees, minutes, and seconds in an angle, to express the same in theoretical units, the following table is given:—

	Degrees.	Minutes.	Seconds.
1	·01745329	·00029089	·00000485
2	·03490659	·00058178	·00000970
3	·05235988	·00087266	·00001454
4	·06981317	·00116355	·00001939
5	·08726646	·00145444	·00002424
6	·10471976	·00174533	·00002909
7	·12217305	·00203622	·00003393
8	·13962634	·00232710	·00003879
9	·15707963	·00261799	·00004363

EXAMPLE.—It is required to express in theoretical units the angle $89^\circ 52' 34''$. Take out the row corresponding to each figure from the column having the same denomination, taking seven places only for a unit's figure, and the whole eight places for the tens, increasing the last figure when necessary, as before: add and make seven decimal places.

For 80° 1'3962634
.. 9° ·1570796
.. $50'$ 0'0145444
.. $2''$ ·0005818
.. $30''$ 0'0001454
.. $4''$ ·0000194

1'5686340

and the answer is 1'5686340.

Given any angle, and a radius, required the circular arc subtended by that angle; proceed as above and then multiply by the radius. Thus to a radius of 100 feet, the arc which subtends an angle of $89^\circ 52' 34''$ is

1'5686340 \times 100 or 156'86340 feet.

In the attempt to effect a universal change of weights and measures, which followed the French Revolution, the circle was divided into 400 degrees, each degree into 100 minutes, each minute into 100 seconds, and so on. This innovation obtained only a partial introduction, and is now almost entirely abandoned. When used, it is customary in this country to distinguish the French degrees by the name of *GRADES*, and to denote one grade by 1° or 1^g . The convenience of this method, from its close affinity with the decimal system, is certainly great: for example, grades and decimals of grades, such as $12^\circ 1329$ are converted into grades, minutes, and seconds, by mere separation of the figures: thus, $12^\circ 13' 29''$

It is not necessary to give complete tables of reduction from the new French to the antient system, as they would so seldom be useful; the following is all that is necessary—

18" is	0° 9	or	54'	or	3240"
1'	" 0° 009	"	0' 54	"	3240"
1"	" 0° 00009	"	0' 0054	"	0' 324

The third method of measuring angles, in which they are said to be measured in *time*, is confined to astronomy, and is derived from the complete apparent revolution of the heavens which takes place in 24 hours. That is, if a line revolve round a point at the rate of a whole revolution in 24 hours, or a right angle in 6 hours, the times of moving through different angles are made the measures of their comparative magnitudes. Thus 4^h 32^m 60^s is the angle moved through in 4 hours, 32 minutes, and 60 seconds. The following tables are useful in turning angles measured in degrees, &c., of space into the corresponding measures in time, and the converse.

TIME INTO SPACE.				SPACE INTO TIME.			
Hours.	°	Min. Sec.	° ' "	°	h. m. s.	"	s.
1	15	1	0 15	1	0 4	1	0 067
2	30	2	0 30	2	0 8	2	0 133
3	45	3	0 45	3	0 12	3	0 200
4	60	4	1 0	4	0 16	4	0 267
5	75	5	1 15	5	0 20	5	0 333
6	90	6	1 30	6	0 24	6	0 400
7	105	7	1 45	7	0 28	7	0 467
8	120	8	2 0	8	0 32	8	0 533
9	135	9	2 15	9	0 36	9	0 600
10	150	10	2 30	10	0 40	10	0 667
11	165	11	2 45	11	0 44	11	0 733
12	180	12	3 0	12	0 48	12	0 800
13	195	13	3 15	13	0 52	13	0 867
&c.	&c.	50	12 30	50	3 20	50	3 333
				60	4 0		
				70	4 40		
				80	5 20		
				90	6 0		
				100	6 40		
				200	13 20		
				300	20 0		

In these tables, where there are two headings, either the upper or under of both must be used. The following are examples.

To turn 18^h 11^m 35^s·3 into degrees, &c., of space. From the first table,

18 ^h	is	150°	0'	0"
11 ^m	"	120	0	0
35 ^s	"	2	30	0
3	"	15	0	
30 ^s	"	7	30	
5	"	1	15	
0 ^s ·3	"		4·5	

18^h 11^m 35^s·3 is 272° 53' 49"·5

To turn 97° 54' 23" into hours, &c. From the second table,

90°	is	6 ^h	0 ^m	0 ^s
7°	"	28	0	
50'	"	3	20	
4'	"		16	
20"	"		1 333	
3"	"		0 200	

97° 54' 23" is 6^h 31^m 37^s·533

In astronomy 30° is sometimes called a sign, in allusion to the arc of the ecliptic, through which one of the signs of the zodiac extends: Thus 2° 30' 4" 12" means 63° 4' 12".

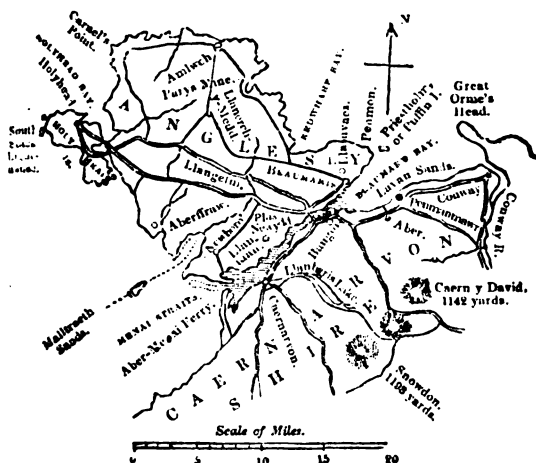

ANGLE (TRISECTION OF). [See TRISECTION.]

ANGLES, or ANGLI. The earliest record of this people we find in Tacitus' book on the Germans (chap. xl.); but this author only mentions their name, states a few particu-

lars relative to their religions, and intimates that they were a branch of the Suevi. Having spoken of the Semnones as the most antient and illustrious tribe of the Suevi, he thus continues: 'But the Langobards are ennobled by their small number; being surrounded by a multitude of the most valiant nations, they live in a state of security, not by submitting to them, but by fighting battles and braving dangers. After them follow (in this description he is proceeding north-westward) the Reudigni, the Aviones, the Angli, the Varini, the Eudoses, the Suardones, and the Nuithones; all these are protected by woods and rivers. Singly, these nations present nothing that is remarkable, except that they in common worship *Hertha*, that is, Mother Earth, believe that she interferes with human affairs, and journeys in a chariot among the nations. In an island in the ocean there is a holy grove where a consecrated vehicle is kept, covered with a vest: nobody but the priest is permitted to touch it. He knows when the goddess is present in this sanctuary, and putting cows to the vehicle he honours her with great devotion. These are days of rejoicing, and festivals are kept in whatever place the goddess visits, and honours with her presence. During these days they do not go to war, nor take arms in hand; hostile weapons are laid aside: peace and quietness only prevail, and are cultivated till the priest brings back to her temple the goddess satiated with the converse of mortals: immediately thereafter the chariot and the vests, and if we choose to believe it, the goddess herself are washed in a secret lake. Slaves perform this service, who are instantly swallowed up by the lake. From this a mysterious fear arises, and a holy wonderment at what that can be which is beheld only by men who must lose their lives. This portion of the Suevi extends into those parts of Germany which are *less known*. This description at all events will convince most readers that Tacitus knew very little about these nations. Lindenbrog and Leibnitz (*Scriptor. Rerum Brunsvicens.* tom. i. p. 81) have preserved fragments of the antient laws used in common by the Angli and the Varini. D'Anville has in his map assigned to them the same district which they occupied in the fifth century before their emigration to England, and parts of which the modern Angles still occupy. He allots to them the greatest portion of modern Schleswig and some part of Holstein, making the German ocean their western boundary, the Saxons their nearest neighbours on the south, the Varini on the south-east, and the Jutes on the north. It is impossible to fix with accuracy any boundaries for the Angli from the account given by Tacitus, but his statement appears perfectly reconcilable with D'Anville's map and the Saxon Chronicle; and it is remarkable that D'Anville in every respect agrees with the last-mentioned record, although it may be doubted whether he knew it, or paid any attention to it. The difficulties raised by German critics and historians, such as Haus and Dörfer, that the Angles, if inhabiting only the district of modern *Angeln*, were too insignificant a nation to occupy Great Britain, are indeed idle: for 1st. it has never been asserted that their domain did not extend beyond the boundaries of modern *Angeln*; 2d. the numbers which Hengist and Horsa first led over to England to the assistance of Vortigern against the Pihts were not so great, as to render it impossible even for a small tract of land, inhabited by a warlike race of men, to produce them: 3d. it was never asserted that the Angles *alone* occupied England, but that soon after their first attempt the Saxons and the Jutes joined them, or co-operated with them; 4th. these critics do not sufficiently attend to the circumstance, that the occupation of England was effected as much by circumvention as by open force, and that the Angles obtained new allies in the Pihts whom they at first came to expel. It is, therefore, needless to extend the boundaries of the Angli to the Elbe and Travemünde: or even to spread them over the whole of the Cimbric Chersonesus (Modern Jutland). [See SAXONS.]

ANGLESEY, or ANGLESEA, an island in the Irish sea, on the north-west coast of Wales, in which principally it is included, and from the main land of which it is separated by the narrow strait, (or, as it is sometimes, though incorrectly, termed, river,) Menai. This strait has a direction very nearly north-east and south-west, with little variation throughout its course. It is thought that Anglesey was once united with the main by an isthmus, at a place called Pwll Ceris, where may still be traced a line of small rocks crossing the channel. It appears also that the Menai

wider than formerly, lines of stones having been observed below the present high-water mark, which seem to have

been once boundaries or fences between the sea and the land. (Rowlands's *Mona Restaurata*.) From the south-west end of this channel, the coast runs in a north-west direction to the farthest point of Holyhead Island, which is separated from the rest of Anglesey by a sandy strait, across which the Holyhead road is carried by a long embankment or causeway, in the centre of which is an opening for the water, arched over. The general direction of the coast on the north-east side of Anglesey is similar to that on the south-west side, (viz., north-west and south-east,) except near Beaumaris, where the land juts out into the sea. The remaining part of the coast from the extremity of Holyhead Island first curves inward, forming Holyhead bay, and then runs east to beyond Amlwch. The length of a line drawn from south-west to north-east, along the shore of the Menai from Aber-Menai Ferry to Trwyndŷ Point, opposite the little island of Priestholm, is 17 miles: a line drawn at right angles to the above from Carnel's Point, in the north-west, to the Menai, is about 20 miles long; and these may be taken as the breadth and length of the island. A much longer line may, however, be drawn, running nearly east and west, from the extremity of Holyhead Island to Point Trwyndŷ, mentioned above; this distance is about 27 miles. (Evans's large *Map of North Wales*, Llwynygroes, 1795.) The number of square miles of surface is variously given. The population, in 1831, was 48,300. There are several smaller islands round the coast. Holyhead, the largest of these, is at the western extremity; Priestholm, or Puffin Island*, at the eastern; the others are insignificant. This island had, in early times, the names of Ynys-Dowell, (the shady or dark island,) Ynys-Fon, (the farthestmost island,) and Ynys-y-Cedeirn (the island of heroes). By the Latin historians it is called Mona (which name it shared with the Isle of Man); the name of Anglesey, (Angle's ey, Englishman's Island), it received from the Saxons. It was a great seat of Druidical superstition. Suetonius Paulinus, the Roman commander, landed here (A.D. 61) in spite of the resistance of the natives, and the terrors which the Druids sought to strike into the hearts of the invaders: he cut down the sacred groves, and gave a blow to the Druidical superstition, from which it never recovered. The island was abandoned by the Romans for a time in consequence of the great revolt under Boadicea, and again conquered by Agricola A.D. 76. Several Druidical remains still exist, cromlechs (flat stones resting upon others) and carnedd's (heaps of stones) of two cromlechs in the park of Plas Newydd, the seat of the Marquis of Anglesey, the larger has its upper stone 12 feet 7 inches long, 12 feet broad, and 4 feet thick, supported by five tall stones. There is at Tre'r Dryw, in the parish of Llanidan, a large circular inclosure 180 feet in diameter, surrounded by a mound of earth and stones evidently brought from other parts, for the bottom of the bank, within and without, is level with the ground on which it is raised (Rowlands). It is supposed to have been the seat of a Druidical consistory. Near are the remains of a cromlech and a Gorseddau, or heap of stones, now dispersed, and of a large circle of stones. Rowlands supposes the whole to have been sur-

rounded by an oak grove. In the neighbourhood are the remains of a square entrenchment with a double rampart and moat, called Caer-leb, and some other relics of Druidical structures. Caer-leb is supposed to have been the residence of the archdruid.

[Cromlech in the Park of Plas Newydd.]

Egbert, monarch of the West Saxons, conquered the island in the former part of the ninth century, but the princes of North Wales having recovered it, Aberffraw, one of its towns, became the seat of government, and continued to be so till the final subjugation of Wales. During the reign of our William II., (Rufus,) near the close of the eleventh century, Anglesey was again attacked and ravaged by the English, in retaliation for some depredations committed by the Welsh borderers. It was laid waste in the following century during the civil contests of the Welsh themselves, unsuccessfully invaded by the Irish in the time of Henry III. A.D. 1245; and finally subdued by Edward I., a detachment of whose army was cut off by an unexpected onset from the inhabitants after they had appeared to submit. It was again made the scene of contest in the struggle between Charles I. and his parliament. [See BRAUMARIS.]

The climate of Anglesey is rendered by the sea breezes milder than that of the adjoining part of Wales; snow seldom lies long, even in the depth of winter; but the air is, from the same cause, loaded with frequent mists in autumn, at which season intermittent fevers prevail. The surface of the island is comparatively flat, and the absence of wood, as well as of quickset hedges, gives it a barren appearance. The air is so unfavourable to the growth of trees, that in most parts the gentry can with difficulty raise a plantation around their own houses. There are, however, considerable woods in the neighbourhood of Beaumaris, and at Plas Newydd, the seat of the Marquis of Anglesey, on the Menai Strait. The limited extent of the island does not admit the formation of any considerable stream. Many rivulets descend from the interior, but none of them have any claim to notice. The coast forms several harbours, the principal of which are Beaumaris and Holyhead. That of Amlwch has been formed by excavating the rock. Anglesey was formerly a place of considerable trade, and the names of ports and havens yet remain, the use of which has long been given up.

The soil of the island is various: the lands on the sea-coast, especially on the western side, are sandy: the low grounds are chiefly covered with a black soil, approximating to peat earth, from which the peasantry dig turf for fuel, and in which they frequently find large trunks of trees, hard and black as ebony, buried several feet under ground. The more prevalent soil is, however, a stiffish loam, which, when manured with sand, produces abundant crops. The sand chiefly used as manure is that from the western side of Redwharf Bay, on the east coast; it has a large intermixture, amounting to two-thirds, or from that to four-fifths, of sea shells. Various kinds of marl are found in the island, but the use of these as manures has declined: lime is used abundantly. The chief agricultural productions are oats and barley; of wheat the proportion is small, and of rye still smaller. Potatoes are grown in greater quantity than in any other part of North Wales, and the cultivation of the turnip is on the increase. Pasturage is, however, the great object of the farmers' attention, for only one-eleventh of the enclosed lands is estimated to be under tillage. Cattle form

* This island takes its name from the number of the puffins which frequent it. During part of the summer it swarms with these and other birds of passage.

one of the staple productions of the island, and numerous herds are exported. These, before the erection of the bridge, were compelled to swim over the Menai strait. The yearly export is estimated at about 8000 head, but such numbers are of course liable to change. The dairy is so little regarded, that the produce of it is hardly sufficient for the consumption of the island. The Anglesey sheep are the largest native breed in North Wales; they have white faces and legs, and are generally without horns. The export is from 5000 to 7000 head annually. The export of hogs used to be considerable, but the quantity of Irish pigs brought to England has, in a great degree, caused it to be given up. The horses are in no repute. (Davies's *General View of the Agriculture of North Wales*.)

The coasts of Anglesey supply an abundance of fish; some of which are not common elsewhere. Shell-fish are abundant.

The mineral riches are also great. The Mona and Parys copper mines, on the north-east coast, began to be worked about 1762, but at first with little success; they have since produced immense wealth to the proprietors. (See AMLWCH.) Mr. Pennant supposes these mines to have been worked by the Romans, and traces of the antient operations were perceived by him. Lead ore, rich in silver, has been found also in Parys Mountain. Limestone ranges traverse the island; marbles, both white and variegated, are procured; mill-stones are quarried at Redwharf and Penmon; and there are coal-mines at Malltraeth, but they do not appear to have been worked with much success. They are, however, remarkable in a geological point of view, because they afford the only known instance in this country of a coal formation in the slate. The coal-field is irregular and uncertain. Several unprofitable trials have been made, and occasionally coal has been worked to a considerable extent. In one pit a vein three feet and a half thick was found at a depth of only twenty-five yards. A singular phenomenon occurs in this formation: large alluvial boulders of coal, some of which weigh a ton or upwards, are found scattered upon the surface. (See COAL FIELDS.) It may be observed, that Anglesey is the only part of the whole principality of Wales in which granite has been observed, and there only in a small spot near the centre. The inhabitants do not carry on any great manufacture: they buy wool at Caernarvon and Bangor fairs, and make coarse blue cloths, blankets, flannels, &c., just sufficient for their own use.

The main road to Holyhead, the usual place of embarkation for Dublin, runs through the island. It crosses the Menai Strait over a magnificent suspension-bridge, the under side of the roadway of which is about 100 feet above high-water mark, so as to admit the passage of the largest vessels which navigate the strait; and the distance from centre to centre of the pyramids of masonry from which the bridge is suspended is 580 feet, rather more than the width of the strait at low water, but considerably less than the width when the tide is up. (Provis's *Historical and Descriptive Account of the Menai Bridge*.)

The communication between the island and the main was formerly entirely by ferries, of which there were five or six; that of Porthaethwy, or Bangor, now superseded by the Menai Bridge, being the principal.

The county of Anglesey is divided into three cantrefs, a division which originated at a very early period; and these cantrefs are subdivided each into two comots (cwmwds). Of the period when the subdivision was made, there appears to be some doubt. For civil purposes, these comots are equivalent to hundreds. It is in the diocese of Bangor and in the province of Canterbury, and in the North Wales circuit.

The market towns are Beaumaris, (population in 1831, 2497,) the county town, on the south-east coast (see BEAUMARIS); Holyhead (population 4282), the great place of embarkation for Ireland, situated on an island of the same name, on the west coast (see HOLYHEAD); Llannerch-y-Medd, on the road to Amlwch, with a market, once the most considerable in Anglesey, but of less extent since the opening of that at Llangefni; Llangefni, a few miles from the Menai Bridge, on the road to Holyhead (population 1753); Aberfraw, on the south-west coast, once the residence of the Welsh princes (population 1367); and Newborough, not far south-east of Aberfraw (population 804); but the markets of the last two seem to have come into disuse, while a customary one has grown up at Amlwch (population

6285),* a place of greater importance than either. (See AMLWCH.) Holyhead, Amlwch, and Llangefni, are now united with Beaumaris in the privilege of returning a member to parliament; and the county returns another. The county election and that for the united boroughs are both held at Beaumaris; and the poll for the county is taken at Beaumaris, Holyhead, and Llangefni.

The chief gentlemen's seats are Plas Newydd, on the Menai, the seat of the Marquis of Anglesea; and Baron Hill, near Beaumaris, the seat of Sir R. B. Williams Bulkley, Bart. There are few antiquities except Druidical, the chief of which have been noticed above. Beaumaris castle will be noticed in the article BEAUMARIS; there are also the remains of a priory at Llanvaes, and of another at Penmon, both in the same neighbourhood. The conventual church of the latter is used as the parish church. An agricultural society was established in the island in 1808. The measures in use here differ from the common ones; the acre of land is about two-thirds of the statute acre, and the yard of cloth contains forty inches. (Rowlands's *Mona Antiqua Restaurata*; Pennant's and Bingley's *Tours in North Wales*; Davies's *Gen. View of the Agric. of North Wales*.)

ANGLO-SAXONS. [See SAXONS.]

ANGOLA, a country on the west coast of Africa. According to M. Degrandpré, a French officer of marine, whose *Voyage à la Côte Occidentale d'Afrique, fait dans les années 1786 et 1787*, appeared at Paris in two volumes, 8vo., in 1801, the name is often used to comprehend the whole extent of coast from Cape Lopez Gonsalvo in lat. 0° 44' S. to S. Felipe de Benguela, in 12° 14' S. The whole of this space appears to be considered as one country by the natives; but by them it is called, not Angola, but Congo, and is divided into the separate districts of Loango, Congo Proper, Angola, and Benguela. The country properly called Angola commences only about lat. 8° 26' S., where it is divided by the river Danda from Congo, and is bounded on the south by the river Coanza, in lat. 9° 20' S. The country immediately to the south of the Coanza is commonly considered to be part of Benguela, although that name appears to be sometimes used as applicable only to the country to the south of the river Catumbela, immediately above S. Felipe de Benguela, at most to that south from the river Longa in lat. 11°. Anciently, Benguela, which afterwards became a separate kingdom, is said to have formed one of the provinces of Angola, and to have extended as far south as to Cape Negro, in lat. 16° S. This is the account given by Father J. A. Cavazzi de Monte Cuculo, a Jesuit, who resided in Angola for many years as a missionary, and whose description of the country may be found in Labat's *Relation Historique de l'Ethiopie Occidentale*, 5 vols., 12mo., Paris, 1732. The proper name of Angola is said to be Dongo-Angola; and Dongo is the abbreviation most in use among the natives, or at least among those on the coast.

The coast of Angola was first discovered by the Portuguese navigator, Diego Cam, in 1486. Very soon after this the Portuguese began to form settlements both along the banks of the Zaire, and at various points of the coast to the south of that river. It was not, however, till 1578 that the town of Loando San Paolo, commonly called St. Paul de Loando, the capital of Angola, was begun to be built. Since then, the Portuguese governor has resided here, and has been called governor of Angola, instead of governor of Congo, as formerly. In 1640, the Portuguese were driven from St. Paul by the Dutch, who retained possession of the place till 1648, when it was recovered by its former masters. It has ever since remained in the hands of Portugal.

Mr. Bowdich, in his *Account of the Discoveries of the Portuguese in the Interior of Angola and Mozambique*, states, on information derived from Count Saldanha de Gama, who had been governor-general of Angola, that the Portuguese settlements extend into the interior for about seven hundred miles from that coast. It is not to be understood, however, that the whole of this territory is, in any sense, under the dominion of the crown of Portugal. It only possesses a few forts, and some commercial establishments, called *Fairas*, or Fairs, at great distances from each other. Two of the fairs are seven hundred miles inland, and are under the superintendence of a Portuguese resident. The Portuguese colonists and the natives meet at these stations for the pur-

* The population given is that of the parishes. These are often more extensive than the towns; that of Amlwch contains part of the town of Llannerch-y-Medd, which is in different parishes.

poses of exchange. In one of Mr. Bowdich's maps, Cahenda, which is called the most distant of these fairs, is placed between the 18th and 19th meridians; but in another, two fairs are set down near each other, in about long. 23° E. Cahenda is on the south bank of the river Manibella, which appears to be the origin of the Benga. There is, or was, a capuchin mission here. Lower down the river is Bangoa Quitamba, in long. 17°, where a carmelite mission is stated to have been established. The forts in the interior of Angola, laid down in Mr. Bowdich's map,—which was constructed in 1790, partly from personal inspection, by Lieutenant-colonel Furtado, an officer of engineers,—are Fort Massangano, at the junction of the river Lucala with the Coanza, about long. 16° 15' E. from Greenwich; Fort Cambambe, higher up the Coanza; Pungo Andongo, at the junction of the Gango, or Moconga, which flows from the south, with the Coanza, a little beyond the 18th meridian; Fort Pedras, in the same vicinity, but not on the river; and Fort Ambaca on the Lucala, about long. 17° 35'. At Massangano there is a garrison of a hundred infantry, and one of sixty at each of the other forts, formed of natives, but commanded by Portuguese officers.

The force kept up at Loando, according to Count Saldanha, is always composed of one regiment of the line, a thousand strong, three hundred cavalry, and two hundred artillery. Descriptions of this town may be found in a *Voyage to Congo made in the Years 1666 and 1667*, by the fathers Angelo and Carli, and in Merolla's *Voyage to Congo in 1682*. Translations of both are printed in the 16th volume of Pinkerton's *Voyages*, and also in Churchill's *Collection*. The city, which in Mr. Bowdich's map is placed in lat. 8° 45' S., is built partly on the mainland, and partly on the Island of Loando, which lies about a mile from the shore, and according to Merolla is ten leagues in length. Bowdich says, that it varies from one hundred to three hundred yards in breadth. St. Paul de Loando was formerly celebrated for the magnificence of its churches and other ecclesiastical buildings. Cavazzi speaks of it as being surrounded, instead of bastions, by temples and monasteries. Besides a cathedral, it contained in those days a convent, an hospital, and a Jesuit's college of great extent. It was formerly the seat of a bishopric; but the bishop, Count Saldanha thought, had taken up his residence in one of the Azores. Both Captain Owen, in H. M. S. the *Leven*, and Captain Vidal, in the *Barracouta*, touched here in 1825, in the course of their survey of the African coast. Captain Vidal, sailing towards the north, arrived off St. Paul, on the afternoon of the 8th of November, when guns were fired at the ship from a large battery hewn in a rocky cliff, and presenting a double tier of artillery. The *Leven* arrived on the 6th of December, and both ships remained till the 19th of that month. The present town is described as situated considerably to the north of the ancient town and port, the former of which is in ruins, and the latter blocked up. The churches and other public buildings were found to be in a state of great decay, and the garrison is stated to consist of only six hundred men. The soldiers are said to be mostly convicts. Mention is made, however, in another place, of a respectable corps of cavalry, which, perhaps, is not included in the number just quoted. The principal part of the city stands on an eminence, which juts out towards the island, and on the extremity of which the largest citadel is placed. There are two other batteries besides this. The low-lying part of the town, however, is the most crowded. It is inhabited, for the most part, by the negroes of the country, and consists merely of a crowd of mean hovels. Bowdich states the whole population of St. Paul at 8000. The entire length of the town is described, in Captain Owen's *Voyage*, as extending for about a mile and three-quarters along the shore. The new harbour is three miles and a half long, and deep and commodious. The market was found to be well supplied with fruit and vegetables, and bullocks and goats were also in great plenty. The country around is described as dusty and parched; but the town is well supplied with excellent water brought daily in tank-boats from the river Benga, which flows into the sea some miles to the north of St. Paul. The old accounts say that plenty of good water is found by digging in the Isle of Loando. This vicinity, according to the account in Captain Owen's *Voyage*, is the only part of the west coast of Africa, to the south of the Gambia, where horses will thrive.

The most detailed account that has been given of the geo-

graphy of Angola is that furnished in Labat's book, principally from the work of Father Cavazzi. But of the seventeen provinces, into which he describes the country as having been antiently divided, only the following seven belong to what is properly called Angola:—Loando, that in which the capital is situated; Danda, adjacent to the river of the same name, described as abounding in corn, fruit, and venison; Benga, on the banks of the Benga, (otherwise called the Zenza,) and altogether inland; Moseche, between the Lucala and the Coanza, being the province in which the two forts of Massangano and Cambambe are situated; Illamba, between the Danda and the Benga, divided into the lower province next the sea, and the higher, called otherwise Lambo, farther inland; Oarii, to the east of the former, and Embacca, or Membacca, comprehending the upper region of the Lucala, being the province in which the fort called Ambaca by Mr. Bowdich is situated. Various additional particulars may also be collected from Mr. Bowdich's book. Nearly five hundred miles beyond the most distant Portuguese fair is Cassange, where it is stated that, during the government of Count Saldanha, a respectable merchant of the name of Da Costa, who had at one time commanded the militia in the interior, established himself, and lived many years in perfect harmony with the natives. To the north of the Cassanges are the Cachingas, and to the east of them are the Domges, with whom they are always at war, and who are said to maintain a trading connexion with the Portuguese settlement of Mombaca, on the opposite coast of the continent. The natives say, that the Congo and the Coanza have both their source in a great lake, which lies on the eastern limits of Cassange; and also, that there is in that region a third river larger than either of these, which they call the Casati. The Coanza, it appears, has been actually traced by the people of the country to the distance of fifteen days' journey beyond the Quindonga islands, in long. 20° 30', through the territories of the Moganguelas and Somghos, two dependencies of Cassange. The islands of Quindonga in the river were taken possession of by a Portuguese force during the government of Count Saldanha. The district in which they lie is called Mattemba, and is to the east of Upper Illamba, already mentioned. In this neighbourhood, according to some authorities, are the Giagas, or Jagas, whose atrocities make a great figure in all the old accounts. But Mr. Bowdich says that Jaga is an epithet which is borne by the Cassanges, and that it denotes a race who were originally nomadic warriors, in contradistinction to Jova, which means a stationary people. The Giagas mentioned by the old writers certainly resided far to the west of Cassange. To the north of Mattemba, and separated from it by the Lunini, a branch of the Congo, is the district of Ginga, the ancient capital of which, Cabasa, is reported by the natives to be four days' journey north of the Coanza, and three days' journey south of the Congo. It is placed in Mr. Bowdich's map, nearly in 8° S. lat., and on the same meridian with the Quindonga islands. It is necessary to observe, however, that very little dependence is to be placed upon these notices, the very vagueness of which indicates that they have been in great part derived from nothing better than the loosest rumours, while a comparison of the accounts given by different authorities would show them to abound in contradictions and inconsistencies. Both Cavazzi and Father Canneccattim, who resided for some time in Angola as a missionary, and wrote a Grammar and Dictionary of the language of the country, published at Lisbon in 1804 and 1805, make the Giagas to be the people of Mattemba, or Matamba, and to have been so called from one of their queens, Gingha, or Anne Zingha, or Gongo Amena, the history of whose wars with the Portuguese, in the seventeenth century, occupies a large space in Cavazzi's narrative.

The language spoken throughout the whole of Angola Proper is the Bunda, which appears to be merely a dialect of the Congoese, or that spoken as far north as Cape Catharine. It is reported by tradition to have originated in Cassange, and to have been introduced into the parts nearer the coast by conquest. A Grammar and Dictionary of this tongue have been compiled, as we have mentioned above, by Father Canneccattim: and some account of its peculiarities is given by Mr. Bowdich from these works. The most important which he notices are that the singular and plural of the nouns, the voices, tenses, and persons of the verbs are distinguished by prefixes, and the article varies in case and number with the noun. A language

nearly the same appears to be spoken as far east and south as Moolooa, in 13° S. lat. and 32° E. long.; and it is probably not so entirely different from that used in Benguela as Mr. Bowdich asserts. In the account which he gives of the journey made through that country by Gregorio Mendez in 1785, it is stated that at Bumbo, in 14° 40' S. lat. and 14° 45' E. long. the jargon spoken by the natives was found to be easily intelligible to those who understood the Bunda language.

The government, laws, and religion prevailing among the natives of Angola are, in their general features, the same with those of the other negro tribes of Africa. The supreme authority in each district is in the hands of a single ruler, who is subject to no regular control. A tax is levied by the Portuguese from the inhabitants of Loando, and of the other small districts where they have erected forts. Ample details respecting the native superstitions may be found in Labat's volumes. In the course of the sixteenth century various missions were sent out by successive popes with the object of diffusing the knowledge of Christianity among the inhabitants of this part of Africa; and by dint of force as well as of persuasion, a good many converts were made. There is reason to believe, however, that the number of negro Christians in Angola is now very inconsiderable. The most enduring labours of the pious and intrepid missionaries are the accounts which several of them have given to the world of the country which their zeal induced them to visit.

The writer who, in recent times, has professed to give the fullest account of the climate and natural productions of Angola, is M. Degrandpré. But his statements really do not refer to Angola, properly so called, at all, but to Congo; the most southerly port which he had visited being Ambriz, which is only in 7° 20' S. lat., about a whole degree distant from the confines of Angola. This, he says, was the nearest port to St. Paul at which the Portuguese would suffer foreign ships to touch. From other authorities it appears that the country, though hilly, is not so much so as a great part of Benguela. Cavazzi describes the confines next Congo as defended by high mountains and sandy deserts. There are no considerable mountains, however, in the space between the Danda and the Coanza until you proceed up the country as far as to the higher Illamba. The hills then rise beyond each other in successive terraces. The rivers, with the exception of the principal branch of the Coanza, all appear to originate in this district, or in those farther to the east. Most of them have been already mentioned, and they all fall into the sea either by the Danda, the Benga, or the Coanza. In the higher Illamba, Cavazzi states, are iron-mines, being the same, we suppose, which are mentioned by Mr. Bowdich as having first begun to be wrought in 1770, but as having been soon after abandoned, on account of the inconvenience occasioned by the frequent inundations of the river Lucala. The attempt to work them, however, was resumed, under the direction of Count Saldanha, with more success, a hundred and fifty bars of iron being brought monthly from these mines to St. Paul, besides what was disposed of in the interior. In other parts gold dust is said to have been formerly found; but Mr. Bowdich states that there is none now. Mines of copper are said to exist somewhere in the interior; but what the Cassanges sell to the Portuguese comes from Moolooa, which, as already mentioned, is far to the south of Angola. Petroleum is found in abundance in the province of Danda.

The rains are stated to be so irregular, that sometimes there are none for three years. On the other hand, there is occasionally a heavy rain which lasts for many days.

The principal commerce of Angola is carried on with Brazil, to which country many thousands of slaves have for a long period been annually exported. Mr. Bowdich has printed some accounts relating to the trade between Angola and Lisbon during the years 1803 and 1804, from which it appears that the only imports into Lisbon from Angola were, in the former year, 289 quintals of ivory, valued at 2,336,000 reis, and in the latter 750½ quintals, valued at 4,779,000 reis. The exports to Angola from Lisbon are stated as consisting of wine, brandy, oil, pork, and other provisions; silks, linens, cottons, flannels and other woollens; hats, glass, gold and silver ornaments, earthenware, hardware, muskets, drugs, paper, and sundry other articles, such as might be supposed to be required for the use of the colonists, to the amount (including some imports from Asia) of 480,789,312 reis in 1803, and of 586,978,145 reis in 1804. These two

sums would amount severally in English money to about 130,000*l.* and 160,000*l.* Such a consumption of foreign commodities would not indicate either a large population of European colonists, or an extensive demand for such foreign productions by the natives; but it is probable that there were also some imports from Brazil.

The physical geography of this portion of Africa, and of the adjacent regions, will be treated of under the head of Congo.

ANGORA. [See ANCYRA.]

ANGOSTU'RA, a town in South America, on the banks of the Orinoco, in the Republic of Colombia, at a distance of about 240 miles from the mouth of the river, in 8° 8' 11" N. lat., and 66° 55' 21" W. long. The town is built on the southern bank at a place where the bed of the river is narrowed on both sides by rocks, and to this circumstance it owes its usual name, signifying the *Strait*; its proper name is *Santo Tomé de la Nueva Guayana*.

The town lies between the foot of a hill and the river, and the houses stand partly on the bare rock; they are, in general, lofty, agreeable, and the greater part built of stone. On the tops are terraces, where people sleep in the season of the greatest heat, without receiving from the dew any injury to their health or sight. The streets are regular, and for the most part parallel to the course of the river. In 1807, Angostura had a population of about 8500 persons, among whom were 300 negroes. At present it is said not to exceed 3000.

Opposite to the town, on the left bank of the river, there is a fort, called *San Rafael*, which is surrounded by a number of houses. This place connects the parts of South America north of the river with Angostura. In the middle of the river, between both places, is a rocky island, called from its situation *Del Medio*, (the middle,) which sometimes, though rarely, is under water during floods. To the south-west of the town, but contiguous to it, is another fort, called *San Gabriel*. The narrowest part of the river lies between the two forts, and here its breadth was found by Baron Humboldt to be 2430 English feet; opposite the town it was 3134 feet. When the waters are high, the river inundates the keys, and it has happened that careless people have become the prey of alligators even in the streets.

Though at so great a distance from the ocean, the town is only about 191 feet above the level of the sea. To the east of it as far as the mouth of the river, a level plain extends; but still more extensive are the plains on the west, which stretch up to the base of the Cordilleras, near Pamplona and Santa Fe de Bogotá. The western plains are known by the name of *Llanos* (levels). In the rainy season, from April till November, these plains are mostly inundated. Notwithstanding its trifling elevation above the level of the sea, and its tropical situation, Angostura enjoys a mild and equal temperature. It seldom happens that Fahrenheit's thermometer rises above 86° in the hottest time of the year; and from the beginning of November to the end of April, it rarely attains 77° during the day, and generally descends only to 69° or 70° at night. This is, in part, to be attributed to the trade-winds, which, according to Depons, blow very regularly from the month of November to the month of May; this, we believe, is a single instance where these winds extend to such a distance from the sea, and are not broken when they reach the land. The low coast at the outlet of the river, and the level plain between the sea and the town is, doubtless, the cause of this phenomenon. In the remainder of the year, the tradewinds are interrupted by calms, more or less frequent and long. Earthquakes have not occurred; sometimes a wind blows with the violence of a hurricane, but it does not last long, and terminates in rain.

The trade of Angostura, though at present nearly annihilated by the disturbed state of the country, will probably revive and become very great; before the beginning of the civil wars it was considerable. In this respect it is very advantageously situated. The channel between the town and the island *Del Medio* has 200 feet of water, when low, and on the increase of the river 50 or 60 feet more. But large vessels cannot sail up to the town on account of the shoals, which are very frequent in the lower part of the Orinoco. Only such as do not draw more than eight feet can navigate it with ease. The best vessels require fifteen days to sail from its mouths to Angostura; but otherwise the mouths of the Orinoco have an advantage over every other part of Colombia. A voyage from Europe to *Punta Barima* (at

southern embouchure) is performed sometimes in eighteen or twenty days, and the return to Europe takes from thirty to thirty-six days; besides, as the mouths of the river are placed to the windward of all the islands, the vessels of Angostura can maintain a more advantageous intercourse with the West Indies, and especially with Trinidad, than either La Guayra or Porto Cabello.

The inland trade of Angostura extends to a great distance to the west: the numerous large rivers which run from the eastern declivity of the Cordilleras to the Orinoco are navigable up to the foot of the mountain-range, and facilitate the transport of every sort of commodities: thus, the produce of the rich country about Varinas is not conveyed to the northern coast, which, though not very distant, is separated by a high range of mountains, but it descends the Orinoco and its tributaries, though the sea in this direction is more than four times as distant. The trade of Angostura with the country round Varinas was very active, and the town received from it considerable quantities of cacao, indigo, cotton, and sugar. It sent back the produce of the manufacturing industry of Europe. Humboldt saw long-boats depart from Angostura for Varinas, the cargoes of which were valued at eight or ten thousand Spanish dollars. These boats went first up the Orinoco to Cabruta at the mouth of the river Apure; then along the latter river to San Vincente and hence on the river Rio Santo Domingo as far as Torunos, which is the port of Varinas Nuevas. The little town of San Fernando de Apure is the magazine of this river trade, which doubtless will become very considerable as soon as tranquillity is completely established in the republic. Many of the other rivers falling into the Orinoco will in future send similar commodities to Angostura, but the country on their banks is as yet uncultivated, and occupied only by savage nations. The Llanos themselves, though they are not cultivated, nor probably fit for cultivation, afford some very valuable articles of commerce. For the greatest part of the year they are covered with a fine rich grass, and innumerable herds of cattle, horses, and mules pasture on them. Great numbers of them were annually exported from Angostura to Trinidad and the other islands of the West Indies. The hides, also, and jerked meat form a considerable article of commerce. (*Travels* of Baron Humboldt and Depons.)

ANGOULEME, a city of France, on the left bank of the river Charente, and on the road from Paris to Bordeaux, 287 miles from the capital. It rises on a hill projecting into the valley of the Charente, from the heights which bound it. The air is pure, and the prospect from the ramparts, which have been changed into public walks, is extensive and fine.

The houses in the older parts are ill-built and the streets narrow; but the "*Quartier Neuf*" is much better in these respects. Among the principal buildings are the cathedral, the bridge over the Charente, and the obelisk raised by the late (Bourbon) government to the Dauphiness, whose husband took the title of duke from the town.

The chief manufactures are of paper, which is in good repute, woollen stuffs, and earthenware, coarse and fine: there are also distilleries and sugar works. To these productions of industry, some authorities add linens, copper utensils, and white wax.

It was formerly the capital of the province of Angoumois, but now of the department of Charente. It is also the seat of a bishop, whose see includes the department in which the town is situated, and who is a suffragan of the archbishop of Bordeaux. Before the revolution, it contained ten convents and two abbeys: in one of the last was the burial place of the former counts of Angoulême. It now has a royal naval school, a high school, a library, and a museum of natural history. Population 15,306.

An English traveller, Colonel Keatinge, who visited Angoulême in 1814, describes it as the Chester of France: the ancient houses on the banks of the Charente, a smoothly-flowing river, form a picturesque mass of buildings. Its beauty, however, appears to diminish on a nearer approach, when the bad construction of the place becomes more obvious.

It is a town of great and, indeed, unknown antiquity. It was the Iculisma of the Romans, and its ancient designation may be readily traced in its present one. In the ninth century, it was ruined by the Normans, and twice taken by the Huguenots in the sixteenth century.

Among the more eminent natives of Angoulême were Balzac, and Montalembert, the engineer. Two others have

acquired celebrity by crimes arising from the fierce religious contentions which agitated France in the sixteenth century;—Poltrot and Ravalliac, the assassins of the Duke of Guise and of Henry IV., respectively. (Malte Brun; Balbi; *Dictionnaire Universelle de la France*.)

The arrondissement of Angoulême contains 114 communes, and about 119,000 inhabitants.

ANGOT, a province of Abyssinia. [See AMHARA, ALVAREZ, and the travels of Alvarez.]

ANGOULEME (CHARLES DE VALOIS, DUKE OF), the natural son of Charles IX. of France and Marie Touchet, was born on the 28th of April, 1573, about a year before the death of his father. Being educated for the church, he was, at the age of fourteen, made abbot of Chaise Dieu, and two years after grand prior of France, that is, head of the order of the Hospitalers of St. John of Jerusalem, or Knights of Malta, in that kingdom. This same year, however, having received by the bequest of Catherine de' Medici the earldoms of Auvergne and Lauraguais, he relinquished his ecclesiastical condition; and henceforth he appears chiefly in a military character. He was one of the first to give in his allegiance to Henry IV., in whose cause he fought with distinguished gallantry, at Arques, at Ivry, and at Fontaine Françoise. After the termination of the war, however, he is charged with having been concerned both in the conspiracy of the Marshal de Biron in 1602, and in that fomented in 1604 by the Marchioness de Verneuil, Henry's mistress, who was Angoulême's half-sister, being a daughter of Marie Touchet. For his share in the first of these attempts he was sent to the Bastille, but was soon set at liberty; on the next occasion sentence of death was passed on him, but the punishment was commuted by his royal master into perpetual imprisonment. In 1606, the possessions which had been left him by Catherine de' Medici were taken from him by a decree of the parliament, and bestowed upon the Dauphin, afterwards Louis XIII. In 1616, however, he was released by that king from his long imprisonment; and in 1619 he was made Duke of Angoulême, having till then borne the title of Count of Auvergne. He was also appointed general of the light dragoons of France, and in 1620 was sent on a special embassy to the court of the Emperor Ferdinand II. He afterwards resumed his military career. It was he who in August, 1628, commenced the famous siege of Rochelle, where the Huguenots held out against the royal forces, till they were obliged to surrender after an obstinate defence of nine months. After this he served for some years in Languedoc, Germany, and Flanders, in the war against the house of Austria which occupied the last years of Louis XIII. and the commencement of the reign of his successor. He died at Paris on the 24th of September, 1650. The following works by the Duke of Angoulême were published during his life: *Les Harangues prononcées en l'Assemblée des MM. les Princes Protestants d'Allemagne*, par le Duc d'Angoulême, octavo, 1620; *La Générale et Fidèle Relation de tout ce qui s'est passé en l'île de Ré, envoyée par le roi à la reine sa mère*, octavo, 1627; and *Relation de l'Origine et Succès des Scherifs, et de l'état des royaumes de Maroc, de Fez, et Tamdunt, écrit en Espagnol par Diego de Torrès, et traduit par M. C. D. V. D'A.* (M. Charles de Valois d'Angoulême,) quarto, Paris, 1636. The last is reprinted in the third volume of Ablancourt's translation of Marmol Caravajal's *Description of Africa*, three volumes, quarto, Paris, 1667. The *Mémoires très particuliers du Duc d'Angoulême* were published at Paris in duodecimo, in 1667, by Jacques Bineau, along with some other narratives relating to the same period of French history. The volume was reprinted in 1696; and the Duke's memoirs are also to be found both in the first volume of the *Mémoires particuliers pour servir à l'Histoire de France*, four volumes, duodecimo, 1756, and in the third volume of the *Pièces Fugitives*, published by the Marquis d'Aubais and M. Menard, in three volumes quarto, in 1759. In 1667 an account of the Duke's embassy to Ferdinand II. was published at Paris in a folio volume, by Henry Comte de Béthune, grandson of Philip Comte de Béthune, who was associated with Angoulême on that occasion, and who took indeed the chief management of the negotiation. The Duke of Angoulême was married, first, on the 6th of March, 1591, to Charlotte, daughter of the constable Henry de Montmorency; and, secondly, on the 25th of February, 1644, to Françoise de Nargonne, who survived him many years, dying on the 10th of August, 1715, at the age of ninety-two. He left two sons by his first wife, the eldest of whom,

Henry, was in 1618 consigned to a lunatic asylum, when the other, Louis Emanuel, who had been educated as an ecclesiastic, like his father, relinquished the church for the camp. He succeeded his father as Duke of Angoulême, but at his death, in 1653, left only a daughter, who died in 1696 without issue. It is said that at the beginning of the last century, Bouthillier, bishop of Troyes, was in possession of a collection of manuscript letters by the elder Duke of Angoulême, from the 19th October, 1633, to the 20th December, 1643, and also of a collection of those of his son. (*Biog. Univ.*)

ANGOUMOIS, a district in France, which was united with that of Saintonge, in one province or military government, until that mode of division was superseded at the revolution by the division into departments; it coincided, though not exactly, with the department of Charente. It is watered by the river Charente, which rises within its limits, and pursues a very winding course through it; and by several tributaries of that stream, among which are the Tardoire and the Baudiat, and the Touvre. The Tardoire comes from the province of Limousin, and its waters, after heavy rains, unite with those of the Baudiat; but at other times, both these streams, before their junction, are swallowed up and lost in pits (either open or filled with a sand, through which the water filters) which lie in their course. The water thus accumulated in subterranean reservoirs, is supposed to supply the stream of the Touvre. The Vienne, a feeder of the Loire, just passes through the eastern extremity of this province.

The surface of Angoumois is far from level; but its hills, which are of nearly a uniform height, rise to no great elevation. The climate is healthy, great heat and cold prevailing only for a short time; and the vegetable productions arrive at great perfection: but the soil is so variable in its fertility, and so large a portion of it is barren, that the district cannot be designated as productive, and the coolness of the spring is often very injurious to the vines, the cultivation of which is carried to a great extent. The white wines are delicate; and the brandy (designated from the town of Cognac, in this province) is highly esteemed. Grain of all sorts is raised; wheat, rye, oats, barley, maize: and the most fertile of the arable lands have yielded abundant harvests for ten or twelve years without requiring any manure; some are not even allowed to remain fallow. The fruits are of the finest quality, especially the peaches and pears; walnuts and chestnuts are abundant. The cultivation of the mulberry-tree has been attended to, in order to raise the silk-worm; flax is grown for the sake of the linseed; and to these productions we may add saffron.

Angoumois is a district of considerable interest to the geologist, and rich in mineral treasures. Stone, proper for building, is found in many places, and mill-stones are dug in the hills which border the valley of the Anguienne, a branch of the Charente. Iron mines are abundant; there is a mine of antimony at Menet, and extensive quarries of gypsum (*plâtrières*), in the neighbourhood of Cognac. See article 'Angoumois' in the volumes 'Geographie Physique' of the *Encyclopédie Méthodique*.

The province was anciently governed by counts, but having fallen to the kings of France, was ceded by John*, after the battle of Poitiers, to Edward III. of England. The inhabitants, however, drove out the English, and put themselves again under the French dominion a few years afterwards, namely, in 1371 or 1372. (*Encyclopédie Méthodique, Dictionnaire Universelle de la France.*) [See CHARENTE, ANGOULEME.]

ANGRA, the capital of Terceira, one of the Azores, is on the south coast of the island, 38° 38' N. lat., 27° 15' W. long. Angra stands on an inlet, from which it derives its name; *angra* being a Portuguese word, signifying a small bay or inlet. Angra has always been the residence of the governor: it is also an episcopal town, and contains a cathedral, five parish churches, four monasteries and four convents, and an arsenal. It is fortified and defended by a castle. The old accounts describe Angra as well built, with broad and straight streets: from about 1533, it became a city. It is the residence of French, English, and Dutch consuls, and carries on some trade. The population is probably 15,000 or 16,000.

From the 15th March, 1830, till the recent events in Portugal, Angra was the residence of the regency which

* At the peace of Bretigny A.D. 1360, four years after the battle of Poitiers.

governed in the name of Donna Maria. During this time, its fortifications were strengthened. [See TERCEIRA.]

ANGRAB, a branch of the river TACAZZE, in Abyssinia. ANGUILLA, or Snake Island, so called from its figure, is one of the Antilles, situated in 18° 8' N. lat. and 65° 12' W. long.

This island was first settled by the English, in 1659, and has since continued in their possession. It is so low and flat, that it cannot be seen at a greater distance than four or five leagues. The soil is sandy and unproductive, and the place is deficient both in wood and water. It produces a little sugar and cotton, some tobacco and maize. The town is on the east side, near the north-east end; it is a small place, with very little commerce. The bay in which it stands is so shut in by reefs, as to be of little value as a harbour. Anguilla is very near the north side of the island of Saint Martin: the channel between the two, which in some parts is not more than four miles wide, affords good anchoring ground, in from seven to twenty fathoms water. Several small, low islets lie to the west of Anguilla; the largest of these, Dog Island, has a few inhabitants.

Anguilla is about twenty miles long, and six broad, and contains between 700 and 800 inhabitants. (Purdy's *Colombian Navigator*; Livingston's *Derrotero de las Antillas*.)

ANGULAR SECTIONS. [See TRISECTION, TRIGONOMETRY, (THEOREM, DE MOIVRES').]

ANGULAR VELOCITY. [See VELOCITY.]

ANGUS. [See FORFARSHIRE.]

ANHALT is an ancient principality in the north of Germany, the name of which is derived by some from 'Burg an der Halde' (castle on the steep), and by others from 'Burg von Stein ohne Holt,' or castle of stone without wood. It lies between 51° 35' and 52° 6' of N. lat., and 11° 38' and 12° 34' of E. long.; it is inclosed almost on every side by the Prussian territories, viz., by Brandenburg on the north, Prussian Saxony on the east and south, the earldom of Mansfeld on the south-west, and the territories of Brunswick, and the Prussian circle of Magdeburg, on the north-west. It is watered by the Elbe, which flows through it from east to west, and by its tributaries, the Mulde and Saale: it produces corn, fruit, flax, hemp, tobacco, timber, silver, copper, iron and coals, rears a considerable quantity of cattle and sheep; and contains a population of 133,000 souls, of whom upwards of 130,000 are Protestants both prince and people having embraced the Reformation, and dissolved their monastic institutions, at so early a period of its propagation as between the years 1521 and 1532. Occupying an elongated tract, the largest portion of which lies on the right bank of the Elbe, and of which the greatest length is sixty miles, with a breadth varying from twelve to sixteen, this triple duchy contains nineteen towns, four villages with markets, and 249 other villages. Of the towns, four possess a population exceeding 5000 souls: viz., Dessau about 10,000; Zerbst 8000; Coethen 6500; and Bernburg 5800. The form of government is monarchical, and the sanction of its diets is required to the imposition of taxes, though the fundamental laws rest on the various ordinances promulgated by its princes. This principality, which is exceeded in fertility by no state in Germany, and forms a richly-cultivated plain, excepting where the acclivities of the Hartz Mountains project in the direction of Bernburg, was formerly a compact territory, and its rulers derived their origin from Ascanius, grandson of Japhet, the son of Noah, whose descendants are reputed to have migrated from the marshes of Ascania, in Bithynia, and, at last, to have settled among the forests of Germany. Hence, the princes of Anhalt to this day designate themselves 'Counts of Ascania.' Their ancestral seat was the stronghold of Anhalt, lying on the Hartz, which is said to have been built by Esico of Ballenstaedt, in 940. Its only remains, at the present day, are the crumbling fragments of some of its vaults, and a noble ash, rising from the midst of them, over which floats a red and white banner. There is an inscription to the following effect against its trunk:—'Among ruins and shady foliage,—in memory of a noble ancestry and their achievements, prowess, and piety—with mourning, at the evanescence of earthly things,—and with joyfulness, at the imperishable existence of justice, virtue, faith, hope, and love,—posterity lifts up its regards to a higher sphere. In fact, there is no family in Germany which has produced'

greater number of brave and skilful warriors than the House of Anhalt; beginning with Bernhard, who declined the imperial sceptre in 1198, because he deemed himself 'too corpulent' for such a dignity; or from Wolfgang, one of the staunchest soldiers of the Reformation, who, on being reinstated in his possessions after he had been expelled from them by its opponents, exclaimed, 'Though old and poor, I would give a thousand florins could I but gibbet—a Pope,' down to Leopold, ('biter of bulls,' as he was christened by Prince Eugene, on account of his detestation of the papacy,) who led the Brandenburg troops to victory in the Low Countries and Italy, created the Prussian infantry, and invented the iron ramrod. He stood foremost of five field-m Marshals who distinguished themselves in the Prussian service in the first half of the last century. Upon the death of Joachim, which happened in 1586, (the inheritance of the several branches of the House of Anhalt having been united in his person,) his four sons divided the principality between them; and thence arose the respective sovereignties of *Dessau, Bernburg, Zerbst, and Coethen*.

The third of these became extinct in 1793, and was shared in equal portions among the three surviving branches. Their erection into duchies is of recent date; the prince of Bernburg having been created duke in 1806, and the princes of Dessau and Coethen having been raised to the same dignity in the following year. The three duchies possess, in conjunction with Oldenburg and Schwartzburg, a single vote in the minor assembly of the diet of the Germanic Confederation, but each of them a distinct vote in its plenary assemblies; they furnish a contingent of 1024 men to the army of the Confederation. Their united revenues (according to Malchus) amount to 149,600*l.*, and their public debt to 292,000. (See *BERNBURG, COETHEN, and DESSAU*.)

ANHOLT is a small Danish island, with a lighthouse, between the shores of Jutland in Denmark and Helmsland in Sweden, in the Kattegat, 56° 38' N. lat., 11° 35' E. long. It was taken by the English during the last war, and an ineffectual attempt to recapture it was made by the Danes in 1811. Its inhabitants do not exceed 100 in number, and subsist by catching seals and fish.—Also, the name of a small town on the old Yssel, in Westphalia, nine miles north-east of Nimeguen, with a handsome palace, the residence of the prince of Salm-Salm. Population 1700. By the treaty of Vienna, it was placed under the sovereignty of Prussia.

ANIELLO, TOMMASO, called by corruption Masaniello, a young fisherman, and a native of Amalfi, lived at Naples towards the middle of the seventeenth century, under the government of the Duke d'Arcos, Viceroy of Philip IV. of Spain. Naples was then suffering all the evils of delegated absolute power; its treasures went to Spain, its youth were sent to fill up the ranks of the Spanish army, and both were wasted in ruinous wars for the ambition and selfish views of a distant court. The people were oppressed with taxes, and suffered from the injustice and wanton tyranny of the officers and other agents of a foreign power. Besides the taxes which were laid upon every possible object of necessity or luxury, besides the sale of the crown lands as well as of the communal ones, and the adulteration of the currency, every new viceroy that came was instructed to demand a *gratuitous gift*, for the service of his master. The nobility assembled in their *sedili*, which were the only shadow remaining of the ancient representation of the country, were applied to by the viceroy to vote the amount, and distribute the quota of the gift among the various districts and families. In this manner alone more than one hundred millions of ducats had been paid by Naples into the Spanish treasury from the reign of Charles V., that is to say, in the course of a century. In the year 1647, the Duke d'Arcos, in order to defray the expenses of a war against France, thought, as a last expedient, to levy a tax on fruit and vegetables, the common articles of food of the Neapolitan people. The edict which announced this fresh impost occasioned the greatest ferment, especially among the poor classes of inhabitants. An old priest of the name of Genoino, who had been in prison for some former offence, contributed to inflame the general discontent. Masaniello, who was then about twenty-five years of age, and who, by his humour and natural quickness, was a great favourite among the people of the *mercato*, the great market-place of Naples, spoke loud among his friends against the new tax. His wife had been arrested some time before at the gates of the city, as she was trying to smuggle in some flour, which, like everything else, was a

taxed article. She was kept in prison several days, and her husband had to pay in order to obtain her release. Masaniello had, accordingly, as we might expect, conceived a violent hatred against the Spanish government.

Masaniello was at the head of a troop of young men who were preparing for the great festival of our Lady of the Carmel, by exhibiting sham combats, and a mock attack on a wooden castle. On the 7th of July, 1647, he and his juvenile troop were standing in the market-place, where, in consequence of the obnoxious tax, but few countrymen had come with the produce of their gardens; the people looked sullen and dissatisfied. A dispute arose between a countryman and a customer who had bought some figs as to which of the two was to bear the burden of the tax. The *eletto*, a municipal magistrate, acting as provost of the trade, being appealed to, decided against the countryman; upon which the latter, in a rage, upset the basket of figs on the pavement. A crowd soon collected round the man, who was cursing the tax and the tax-gatherers. Masaniello ran to the spot, crying out 'No taxes, no more taxes!' The cry was caught and repeated by a thousand voices. The *eletto* tried to speak to the multitude, but Masaniello threw a bunch of figs in his face, the rest fell upon him, and he and his attendants escaped with difficulty. Masaniello then addressed the people around him in a speech of coarse, hot, fiery eloquence; he described their common grievances and miseries, and pointed out the necessity of putting a stop to the oppression and avarice of their rulers. 'The Neapolitan people,' said he, 'must pay no more taxes!' The people cried out, 'Let Masaniello be our chief!' The crowd now set itself in motion, with Masaniello at their head: it rolled onward, increasing its numbers at every step; their rage fell first on the toll-houses and booths of the tax-collectors, which were burnt, and next on the houses and palaces of those who had farmed the taxes, or otherwise supported the obnoxious system. Armed with such weapons as they could procure from the gunsmiths' shops and others, they proceeded to the viceroy's palace, forced their way in spite of the guards, and Masaniello and others of his companions having reached the viceroy's presence, peremptorily demanded the abolition of all taxes. The viceroy assented to this; but the tumult increasing, he tried to escape, was personally ill-treated, and at last contrived, by throwing money among the rioters, to withdraw himself into the Castel Nuovo. The palaces were emptied of their furniture, which was carried into the midst of the square and there burnt by Masaniello's directions. Masaniello was now saluted by acclamation as 'Captain-general of the Neapolitan people,' and a platform was raised for him in the square, where he sat in judgment in his fisherman's attire, holding a naked sword in his hand. Thence he issued his orders, and his will was law. The citizens in general, besides the populace, obeyed him, a sort of commonwealth was organized, and the men were armed and distributed into regiments. The few Spanish and German troops of the viceroy were defeated, and obliged to defend themselves within the castles. The viceroy in this extremity proposed Cardinal Filomarino, the archbishop of Naples, who was a man of abilities, and withal popular, to act as mediator between him and the people. Articles were drawn up under Masaniello's direction, by which all imposts upon articles of consumption were abolished, and the privileges granted by Charles V. restored, besides an amnesty to all concerned in the insurrection. It was agreed that these were to receive the viceroy's signature, and an early day was fixed for the purpose. The cardinal, accompanied by Masaniello, dressed in splendid attire and mounted upon a fine charger, proceeded to the Castle Nuovo, followed by an innumerable multitude. The viceroy received Masaniello with every mark of deference, and the conditions were examined and accepted. As Masaniello loitered within the castle, the populace outside grew impatient and tumultuous, when the chief of the people appeared at a balcony, and by a sign of his hand silenced them immediately: at another sign, all the bells tolled and the people shouted *Vivas!* and again, as he placed his finger across his lips, they all became mute. The viceroy being now convinced of the astonishing power of this man, the negotiation was soon concluded, after which the Duke d'Arcos put a gold chain round Masaniello's neck and saluted him as Duke of St. George. Masaniello returned in triumph to his humble dwelling, and peace was momentarily restored.

But Masaniello's mind gave signs of fatal decay: his sudden and giddy elevation, the multiplicity of questions that

were referred to him, his total inexperience of business, the heat of the season, his want of sleep,—all helped to derange his intellects. He had already complained of a sensation 'like that of boiling lead in his head;' he became suspicious, and was in continual dread of traitors, especially after the attempt made by a troop of banditti who had mixed with the people to shoot him on his tribunal in the market-place. The wretches were of course put to summary death, but the fears of Masaniello continued, and he ordered every man, even ecclesiastics, to leave their cloaks and long robes, and appear in short clothes in the streets. Meantime the chief of the people was administering justice from a low window of his house, with a loaded blunderbuss in his hand, and his door surrounded by guards. He showed himself capricious, absurd, and cruel, though cruelty does not appear to have been a vice natural to his character. He began to lose his credit with the multitude; the rebel government besides required money; and, as the only expedient, taxes upon eatables were resorted to again from sheer necessity. Masaniello evidently had no fixed or regular plan; his only idea was to remove the taxes and to humble the nobility, but he had no notion of setting aside the sovereignty of the King of Spain. In his hatred against the Neapolitan nobility, he devoted to destruction sixty palaces, only twenty-four of which, however, were burnt. He pronounced sentences of death with a frightful volubility. His lazzaroni were animated with similar feelings: they carried boat-hooks in their hands, which they said were for the purpose of pulling the gentlemen from their horses. Masaniello at times felt his growing weakness; he talked of abdicating his power and returning to his fishing-nets; but he had gone already too far. Some wretches, among whom was the old priest Genoino, who had been bribed to effect Masaniello's ruin, encouraged him in his mad career. On the 14th of July, being the eighth day of the insurrection, Masaniello took it into his head to proceed on a party of pleasure by sea to the Cape of Posilipo. The viceroy ordered his barge to be got ready for him; and Masaniello went, accompanied by musicians and followed by an immense multitude, who crowded to meet him at his landing. On arriving, he went to mass, it being Sunday, and then threw himself into the sea with his clothes on. After this he sat down to supper, at which he swallowed an enormous quantity of the strongest country wine, and was carried home in a state of intoxication. Next day he repaired, as usual, to his judgment-seat; the people still clung to him, and he was still all-powerful: but he behaved so outrageously on that day, that his friends became convinced of his insanity, and watched him during the night. On the morning of the 16th, being the great holyday of the Virgin, Masaniello escaped from the care of his friends and ran to the church del Carmine, where the archbishop was performing mass. At the end of the service, Masaniello ascended the pulpit, with a crucifix in his hand, and harangued the numerous audience. He earnestly and pathetically reminded them of what he had done for them, he tore his clothes, bared his breast, and showed his body, extenuated by watching and continual anxiety. He entreated them not to abandon him into the hands of his enemies. The people were affected by his address, but all at once poor Masaniello relapsed into one of his fits of aberration; he lost the thread of his discourse, and talked incoherently and wildly. The people began to laugh, and many left the church; Masaniello was taken down from the pulpit by the priests, the archbishop spoke to him kindly, and advised him to rest and calm himself awhile in the adjoining convent. He was taken into one of the cells, where a change of clothes was given him, and he lay down on a couch and rested a few minutes. He soon started up again, and stood looking out of a window in a melancholy mood upon the tranquil and beautiful bay of Naples, which lay stretched before him, thinking, perhaps, of the happier times when he used to glide on the waters in his fishing-boat, when all at once cries were heard in the corridor, calling him by name. Armed men appeared at the cell-door. Masaniello turned towards them: 'Here I am—do my people want me?' A discharge from their arquebuses was the wretches' answer; and Masaniello fell, exclaiming, 'Ungrateful traitors!' and expired. His head was cut off, fixed on a pole, and carried to the viceroy, the body dragged through the streets by a troop of boys, as he had himself foretold a few days before, and then thrown into a ditch. The revolt, however, was not yet quelled: the people, after appointing the Prince of Massa for their chief, whom they soon after murdered, chose Gennaro Annese, one of the vil-

lains who had plotted against Masaniello's life. This chief was soon superseded by the Duke of Guise, who came to try his fortune at Naples as the representative of the ancient house of Anjou. [See GUISE.]

ANIMAL, the general name for living organized beings. This is not intended as a definition: we purposely abstain from attempting one. The classification of animals according to Cuvier's system, is given under the head of **ANATOMY, COMPARATIVE**.

ANIMAL MAGNETISM, a pretended agent of a peculiar nature, supposed to be capable, in some mysterious mode, of producing the most powerful effects on the human body. The rise and progress of animal magnetism affords one of the most striking examples on record of the influence, through the imagination, of the mind upon the body, and at the same time, one of the most curious cases of knavery and credulity in the history of the delusions of the human mind. A brief account of it may be not without amusement and instruction.

It was in the year 1734 that Mersburg in Swabia had the honour of giving birth to Anton Mesmer, the discoverer of animal magnetism. This celebrated man studied physic at Vienna, and took his degree of doctor of medicine in the university of that place, in the year 1776. On that occasion he published an inaugural thesis on the *Influence of the Planets on the Human Body*. It chanced that the professor of astronomy at Vienna, a Jesuit, named father Hehl, the friend of Mesmer, had great faith in the influence of the loadstone on human diseases, and had invented steel plates of a peculiar form which he impregnated with the virtues of the magnet, and applied to the cure of diseases 'with extraordinary success.' Mesmer, who had his own notion of the virtues of the magnet, availed himself of his friend's steel plates to employ the magnet according to his own peculiar views. Wonderful were the results; on the communication of which to father Hehl, his friend published an account of them; but in this account he attributed all the cures to the form of the plates, and spoke of Mesmer as a physician whom he had employed to make his experiments. Mesmer, expressing great indignation at this representation, accused Hehl of treachery, and of endeavouring to turn to his own advantage a discovery with which he had been entrusted in the confidence of friendship. Hereupon arose a violent controversy which ended in the total defeat of Mesmer, who, as if deriving fresh energy from discomfiture, went on working greater cures than before, and making incomparably greater noise about them. Nevertheless, being deserted by all men of science, who universally regarded him as an impostor, he was obliged to quit Vienna. After travelling some time in different parts of Germany and Switzerland, continuing every where to work wonderful cures, at last in a lucky hour he set out for Paris, where he arrived in the year 1778. His first care, on reaching this new and favourable theatre for his exploits, was to procure public apartments for the treatment of patients. And thither speedily flocked peer and peasant in such numbers that his apartments were crowded, and hundreds were ready to attest the wonderful cures wrought upon their own persons by the great magnetizer. In the general excitement, it would have been wonderful if no regular member of the medical faculty had become a convert. Mesmer found a highly useful one in a certain M. d'Eslon, who openly professed his conversion to the system, and who practised it with so much success that he is said to have received in fees from his patients no less a sum than 100,000*l*. The disciple in this proceeded further than was altogether satisfactory to the master. Mesmer complained bitterly that he was betrayed and ruined; and that the fruit of long study and incessant watchings, which it had been the labour of his life to bring to perfection, was snatched from him by another. He now applied to the government, and succeeded in obtaining the patronage of the queen. 'A château and its lands, where he might be enabled to continue his treatments at leisure and independently of persecution,' was what he asked. A life-rent of twenty thousand francs per annum, and in lieu of the château and its lands another sum of ten thousand francs a year to enable him to select a proper situation for the treatment of his patients, were actually offered him. The offer, however, was coupled with one condition, namely, that three persons named by the government should witness and report upon his proceedings. Nevertheless it was stipulated that, even if the report of these persons should prove unfavourable, the sums promised him should not be

forfeited, while, if favourable, he might look for the most splendid rewards. But Mesmer was sharp-sighted enough to foresee that the report would not be favourable, and that the reward would not be continued if undeserved. He therefore suddenly quitted France and repaired to Spa. Thither he was followed by several patients of rank and fortune, who, on condition that he would communicate to them his doctrine and practice, bound themselves to find one hundred persons who would pay him each 2400 francs for his instructions. The sum actually raised by this subscription amounted to 340,000 francs, nearly equal to 14,000*l.* sterling. On receiving this sum, Mesmer returned to Paris and recommenced his public treatments. Meantime his disciples, who had paid thus liberally for his instructions, formed themselves into what they termed *Société de l'Harmonie*, for the purpose of gratuitously propagating the doctrines of animal magnetism. But the master disputed their right to do this: the disciples, on the other hand, maintained that they had purchased the privilege; at all events they resolved to exercise it, and set about doing so; and now Mesmer, seeing no prospect of making any further personal advantage by his discovery, quietly put the money in his purse, quitted France, retired to his native place, and gave himself no further trouble about the success or the failure of animal magnetism.

Such is the history of the discoverer: of the discovery Mesmer himself gives the following account:—'Animal magnetism is a fluid universally diffused; it is the medium of a mutual influence between the heavenly bodies, the earth, and animated bodies; it is continuous, so as to leave no void; its subtilty admits of no comparison; it is capable of receiving, propagating, communicating all the impressions of motion; it is susceptible of flux and of reflux. The animal body experiences the effects of this agent; by insinuating itself into the substance of the nerves it affects them immediately. There are observed, particularly in the human body, properties analogous to those of the magnet; and in it are discerned poles equally different and opposite. The action and the virtues of animal magnetism may be communicated from one body to other bodies, animate and inanimate. This action takes place at a remote distance, without the aid of any intermediate body; it is increased, reflected by mirrors; communicated, propagated, augmented by sound; its virtues may be accumulated, concentrated, transported. Although this fluid is universal, all animal bodies are not equally susceptible of it; there are even some, though a very small number, which have properties so opposite, that their very presence destroys all the effects of this fluid on other bodies. Animal magnetism is capable of healing diseases of the nerves immediately, and others mediately. It perfects the action of medicines; it excites and directs salutary *crises* in such a manner, that the physician may render himself master of them; by its means he knows the state of health of each individual, and judges with certainty of the origin, the nature, and the progress of the most complicated diseases; he prevents their increase, and succeeds in healing them, without at any time exposing his patient to dangerous effects or troublesome consequences, whatever be the age, the temperament, and the sex. In animal magnetism nature presents a universal method of healing and preserving mankind.' (*Mémoire sur la Découverte du Magnétisme Animal*, par M. Mesmer, Paris, 1779, pp. 74, et seq. *Ibid. Avis au Lecteur*, p. 6.)

The mode of bringing the magnetised under the influence of the magnetic fluid was peculiar. In the middle of each room in which the persons to be treated were collected was placed a large circular vessel, made of oak-wood about a foot or a foot and a half in height: the interior of this vessel was filled with pounded glass, iron filings, and bottles containing magnetised water arranged symmetrically: the cover or upper part of the vessel was pierced with numerous holes, in which were placed polished iron rods of various lengths, bent and capable of being moved: this was called the *baquet* or magnetic tub. The patients were placed in successive rows around the *baquet*, and each had one of the rods of iron, the end of which he applied to the part of his body which was supposed to be the seat of his disease: a cord passed around their bodies united the patients to one another, and sometimes they formed a second chain by taking hold of each other's thumbs. A piano-forte was placed in the corner of the room, and various airs were played upon it, sometimes accompanied with the sound of the voice and song. The magnetizer held in his hand a

polished and pointed rod of iron from ten to twelve inches long. The *baquet* was a reservoir of magnetic virtues; its interior arrangement was for the purpose of concentrating the magnetic fluid; the rods were the conductors for transmitting it. The cords around the bodies of the patients and the other chain of connection by the thumbs were for increasing the effects of the fluid by communication. The magnetizer had previously charged the piano-forte with magnetic fluid; the person playing on it was incessantly giving out more; the sound conducted it to the patients. The purpose of the music was to put the patients into a state of quiet; to give them agreeable sensations, and thus to dispose them to receive the magnetic action. The purpose of the magnetizer's rod was to concentrate to a point the fluid which issued from him, and thus to render it more powerful. The sick persons arranged in great numbers and in several rows around the *baquet*, thus receive the magnetism by all these means; by the iron rods which convey to them that of the *baquet*; by the cords wound round their bodies; by the connexion of the thumbs which communicate to them that of their neighbours; by the sound of the piano-forte or of an agreeable voice diffusing the magnetism in the air; by the finger and rod of the magnetizer moved before their faces, above or behind their heads, and on the diseased parts, always observing the direction of the poles; by the eye of the magnetizer; but above all by the application of his hands and the pressure of his fingers on the hypochondria and on the regions of the abdomen; an application often continued for a long time, sometimes for several hours. Meanwhile the patients in their different conditions present a varied picture. Some are calm, tranquil, and experience no effect; others cough, spit, feel slight pains, local or general heat, and have sweatings; others again are agitated or tormented with convulsions. These convulsions are remarkable in regard to the number affected with them and to their duration and force; and are characterized by the precipitous involuntary motions of all the limbs and of the whole body, by the constriction of the throat, by the leaping motions of the hypochondria and the epigastrium; by the dimness and wandering of the eyes; by piercing shrieks, tears, sobbing, and immoderate laughter. They are preceded or followed by a state of languor and reverie, a kind of depression, and even drowsiness. The smallest unforeseen noise occasions shudderings; even a change of tone and measure in the airs played on the piano-forte influences the patients, a quicker motion agitating them more and renewing the vivacity of their convulsions. Nothing is more astonishing than the spectacle of these convulsions; one who has not seen them can form no idea of them. The spectator is equally astonished at the profound repose of one part of the patients and the agitation of the rest; at the various accidents which are repeated and the sympathies which are established. Some patients devote their exclusive attention to each other, rushing towards one another, smiling, speaking with affection and mutually soothing their *crises*. All are under the power of the magnetizer; it matters not in what state of drowsiness they may be—his voice, a look, a gesture brings them out of it.

Such is the account of M. Bailly, who, together with Lavoisier, Franklin, and other distinguished men were appointed by the French government to examine into these splendid pretensions. These commissioners report—'That this pretended agent certainly is not common magnetism, for that, on examining the *baquet*, the grand reservoir of this wonderful fluid, by means of a needle and electrometer, not the slightest indication of the presence either of common magnetism or of electricity was afforded; that it is wholly inappreciable by any of the senses or by any mechanical or chemical process; that they tried it upon themselves and upon many others without being able to perceive anything; that on blindfolding those who seemed to be most susceptible to its influence, all its ordinary effects were produced when nothing was done to them but when they imagined they were magnetized, while none of its effects were produced when they were really magnetized, but imagined nothing was done; that, in like manner, when brought under a magnetized tree nothing happened if the subjects of the experiment thought they were at a distance from the tree, while they were immediately thrown into convulsions if they believed they were near the tree, although really at a distance from it; that, consequently, the effects actually produced were produced purely by the imagination; that these effects, though some cures might be wrought, were not with-

out danger, since the convulsions excited were often violent and exceedingly apt to spread, especially among men feeble in body and weak in mind, and almost universally among women; and finally, that there were parts of the operation of magnetizing which might readily be turned to vicious purposes, and that immoral practices had already actually grown out of them.'

Notwithstanding such a report from men so well qualified to form a judgment, animal magnetism continued to flourish to such a degree, that Dr. Franklin, writing some time after this report had become public, and adverting to the proneness of mankind to credulity, states that Mesmer was at that time getting more money in the shape of fees than all the regular physicians in Paris put together. To this day the belief of it is common, if not general, in Holland, Germany, and other continental nations. The thing never took root in England. There was at one time some danger of it, but it was prevented by the skilful management of a physician of eminence. A man of the name of Perkins had invented a wonderfully convenient instrument for collecting, condensing, and applying animal magnetism, composed of a metallic substance, and called the metallic tractor. For this instrument he had obtained a patent, and its virtues he set forth in a work bearing the following title—*The Efficacy of Perkins's Patent Metallic Tractors in various Diseases of the Human Body and Animals; exemplified by two hundred and fifty cases from the first literary characters in Europe and America. With a Preliminary Discourse in Refutation of the Objections made by Interest and Prejudice to the Metallic Practice.* Dr. William Falconer, of Bath, having made tractors of wood so exactly resembling the patent tractors that it was impossible for the eye to distinguish between the one and the other, tried, in conjunction with Dr. Haygarth, the effect of these fictitious tractors on a large scale on patients in the Bath Hospital, and produced precisely the same effects with the fictitious as with the genuine, affording a demonstration that whatever effects were produced, were produced solely by the imagination. The publication of these cases put an end to the virtues of the metallic tractors in England; but we have little cause to congratulate ourselves on a greater exemption from credulity than our continental neighbours, as we all know by very recent instances. Nothing can prevent the success of such impostors, or put an end to the grievous evils they occasion, but the diffusion among the people of sound knowledge relative to the functions of the animal economy, the nature of diseases, and the mode in which remedies operate in their prevention and cure. See *Report of Benj. Franklin and other Commissioners charged by the King of France with the Examination of Animal Magnetism as now practised at Paris. Translated from the French, with an Historical Introduction*, 8vo. 1785; *The Foreign Review and Continental Miscellany*, No. IX. Nov. 1829, art. Animal Magnetism.

ANIMAL PHYSIOLOGY. [See **PHYSIOLOGY.**]

ANIMALCULES, in zoology, is the name which has been applied to small animals of various classes, which cannot be distinctly seen without the use of a microscope, as the minute radiata animal of the coral, the worms found in paste, vinegar, and vegetable infusions, or the smaller crustacea found in pools, as the *minoculi*. Some of these will be referred to under their proper heads; and a general notice of them will be found under **INFUSORIA**.

ANIO. [See **TEVERONE.**]

ANISE. [See **PIMPERNELLA.**]

ANJAR, a small district in the province of Cutch, in Hindostan. It came into possession of the English in 1816, and was again transferred to the Rao of Cutch in 1819, in consideration of an annual sum of 88,000 rupees to be paid to the East India Company out of the surplus revenues. The government of the district is still, however, virtually exercised by the Company, by means of a resident commissioner deputed from the presidency of Bombay.

The country of Anjar is extremely arid, and suffers much from scarcity of water, which cannot be obtained without sinking wells to a great depth; the soil also is so loose and sandy as to present obstacles to forming tanks. It has been the custom, that any person who sinks a well at his own expense, in an uncultivated tract, should become entitled to appropriate to his own use the whole of the land which he could irrigate by means of its water. The Bombay government having an interest in the prosperity of the cultivators, has caused several tanks to be constructed, in con-

sequence of which tillage has been extended, and the district much improved. (*Report of the House of Commons on the affairs of India, Session 1832; Hamilton's East India Gazetteer.*)

ANJAR, the capital of the district of the same name, is in 23° 3' N. lat., and 70° 11' E. long.

The town is built on the side of a hill, about ten miles from the Gulf of Cutch. The fortifications are not strong, the walls being only six feet in thickness, and without a ditch. Anjar was besieged and taken in 1816 by a British corps. In 1819 it experienced the shock of an earthquake, by which nearly one-half of the houses were thrown down, and about 200 persons were killed. The population in the following year was estimated at 10,000 souls. (*Hamilton's East India Gazetteer.*)

ANJOU, one of the provinces or military governments into which France was divided before the revolution. It includes the present departments of Maine and Loire, with portions of several of the surrounding ones, especially of Sarthe, Mayenne, and Vienne. It comprehends a part of the valley of the Loire, by which river it is traversed in a direction from east to west, and it is watered also by the navigable rivers Loir and Sarthe, which, entering the country from the north-east, unite their streams and fall into the Mayenne, (also navigable,) which, rising in Normandy and crossing Maine, enters Anjou from the north. The Mayenne, having received the Sarthe and Loire, passes the town of Angers, and falls into the Loire. Another feeder of the Mayenne, the Oudon, which flows from the north-west, is also navigable; so that few countries are more favoured by nature with the means of water-conveyance than the part of Anjou north of the Loire. The part south of that great river has only one navigable stream, the Thouet, which falls into the Loire at Saumur, near the western extremity of the province.

Anjou is bounded on the north by Maine, on the east by Touraine, on the south by Poitou, and on the west by Bretagne. Its form is very irregular, especially in the east, where the district of Saumurois runs out to the south-east between Touraine and Poitou. Its capital was Angers, (see **ANGERS**), and nearly the whole country was included in the bishoprick of which that town was the seat.

The climate of Anjou is healthy and mild; and the soil, which is agreeably diversified with hills and plains, is rich in various productions. (*Encyclopédie Methodique; Dict. Univ. de la France, &c.*)

ANJOU, the **Dukes and Counts of**, were amongst the earliest noblesse of France. Some chronicler gives the title to the famous Roland. Charles the Bald, it is said, bestowed the province upon one of his courtiers, from whom the first family of counts, in general named Fulke, were descended. One of this name was amongst the peers who raised Hugh Capet to the throne; and his descendants gallantly defended their county against the lords of Champagne, of Poitou, and of Normandy. A count of Anjou, also styled Fulke, joined the early crusades, and became King of Jerusalem. His son Geoffrey married (in 1127) Matilda, or Maud, daughter and heiress of king Henry I. of England, to the crown of which kingdom he gave as heir, Henry Plantagenet. Thus merged the first house of Anjou. Soon after the conquest of the province, by the French, it was bequeathed by Louis VIII., in 1226, to his fourth son, Charles of Anjou, who commenced the second house of Anjou, and raised it to a height of grandeur and renown no longer proportioned to the little province from which it derived its title. He espoused the daughter of Raymond Berenger, last count of Provence, and through her inherited that extensive fief, including the greater part of the south of France. He accompanied his brother St. Louis in his crusade to Egypt, when he was taken prisoner with that monarch, but soon afterwards ransomed. His government of Provence was marked by rapacity, overbearing cruelty, and contempt for the privileges of his subjects. Such, however, was the prince whom the pope selected for the throne of Naples, in opposition to Manfred and Conradin, the last of the Hohenstaufen. The pontiff was induced to select Charles as his champion by the report of his great wealth, and Charles was forced to accept by the ambition of his wife, who could not endure that she alone of all her sisters went without the title of queen. Charles of Anjou therefore made his preparations in men and money for the conquest of Naples, whilst his ally, the pope, opened to him his spiritual treasures, by preaching a crusade in favour

of Charles against Manfred. The Angevin prince invaded Italy with an army of 30,000 men, in 1265, but that year, and almost another, passed away, before the French entered the kingdom of Naples. Manfred, with a force of Neapolitans, Saracens, and Arabians, took post not far from Beneventum in the plain of Grandella. The French accepted with alacrity the battle that was offered, and it was fought with the utmost gallantry on both sides. The Neapolitan nobles, however, at last deserted their prince, who instantly tearing his crest from his helmet to prevent his being recognised, rushed into the thickest of the fight and was slain. The victory declared for Charles, who made the most cruel use of it. Not only was no mercy shown in the field, but the neighbouring town of Beneventum was given up with its population to the brutal fury and avarice of the soldiers. After this consummation of his crusade, Charles of Anjou made his triumphant entry into Naples. His government bore the same stamp with his conquest; it was but a succession of oppression and rapine. The pope himself was obliged to reproach the new sovereign of his choice, with employing 'none but robbers and brigands, to whom adultery and rape were as familiar as spoiliations.' Such is the pope's record of the effects of the crusade preached by himself.

Charles of Anjou, as head of the Guelphic party in Italy, was more than sovereign of Naples. Ramifications of the two great parties disputed Tuscany also, and Charles marched to chase his enemies, the Ghibelins, from that country. In this enterprise also he succeeded, and the Guelphs of Florence procured his nomination as political chief of that city for a period of ten years.

The Ghibelin party, however, rallied. They summoned young Conradin, nephew of Manfred, from Germany to support their cause, and the young prince advanced with a small but valiant army of Germans into Italy. Recalled to the south by the disaffection of the Neapolitans, Charles was able to offer no effectual resistance to Conradin, till the invader penetrated through the Abruzzi into the kingdom of Naples. 'Never was a country,' says Sismondi, 'more formed for a protracted war of defence by its mountains and its shepherd race, yet the fate of Naples has always been decided by battle in the plain.' (See ABRUZZO.) So was it now. The armies met at Tagliacozzo, 5000 on the German, and 3000 on the Neapolitan side. Of these 3000, Charles placed 800 in ambush, and with them waited till the Germans, having routed the rest, were scattered in the pursuit. He then quitted his ambush, and gained an easy victory. Conradin was taken in flight. Charles did not blush to bring his young competitor to a mock trial, when he was of course condemned to death. This infamous sentence pronounced against the rightful prince, so stirred up the indignation even of Charles's friends, that his very son-in-law, Robert of Flanders, struck the judge, whilst in the act of pronouncing the sentence, with a blow that proved mortal. But this did not prevent young Conradin, together with his friends, amongst whom was the duke of Austria, from being brought to execution, which took place in one of the great squares of Naples. Charles of Anjou was present with all his court. When Conradin laid down his head for the executioner, he flung his glove amongst the weeping crowd, thus challenging an avenger. The glove was picked up and carried to don Peter of Aragon, who had married the daughter of Manfred, and who, under this claim, became the competitor of the House of Anjou.

For the time, however, Charles reigned without opposition, not only over Naples, but over the whole of Italy. An interregnum of the pontificate left Rome at his disposal, whilst almost all the cities of Lombardy imitated Florence in acknowledging him as their protector, and in swearing allegiance to him. Had Charles limited his views to Italy, he might perhaps have formed an independent kingdom of that country, but his boundless ambition drew him off to other enterprises, and instead of founding his dominion in Italy, he began to aspire after that of the East. His superstition, too, seemed to lead him astray; he was guilty of great crimes, and he could not neglect an opportunity of washing them away. This induced him, when his brother St. Louis set out upon a new crusade, to assume the cross. Charles, however, arrived at Tunis only in time to take command of the army which the death of St. Louis had left without a leader, and having satisfied his vow, Charles hastened to make peace on condition that Tunis should be tributary to Sicily. Gain was ever his first object. In re-

turning, he confiscated all the vessels of his allies, the Genoese, which had been wrecked in a storm, claiming them as waifs, although they had been damaged in the service of transporting his army.

But Charles's power, and his dream of founding an empire in Italy, were overthrown by the hands that had raised him. A pope was elected, (Gregory X.,) who had at heart the interest of Christianity, more than those of a party. Instead of crushing the Ghibelins, he sought to reconcile them to the Guelphs, and in order to remove the anarchy of Germany, he procured the nomination of an emperor in the person of Rodolph of Hapsburgh. This was raising a dangerous rival to Charles, who had hitherto ruled the north of Italy in the character of *Imperial Vicar*, conferred on him by the pope. But old, bereft of spirit, and conscious of the general hatred borne to him, Charles was unable to make any effectual resistance. After a year or two of vain manœuvres and complaints, he was obliged to give up the great object of his ambition, and cede to Rodolph the hold which he had usurped over the north of Italy.

A vacancy of the pontificate enabled Charles to rally his party, and recommence his machinations for empire. By surrounding the conclave which met at Viterbo, and getting rid of the cardinals obnoxious to him, he succeeded in procuring the nomination of a pope in his interests. From Martin IV., (so the pontiff was called,) he obtained the preaching of a new crusade, directed however, not against the north of Italy, but of Greece. It was by occupying the throne of Constantinople, that Charles hoped to rise superior to Rodolph, and make good eventually his imperial claim on Italy itself. Whilst engaged in preparations for this great project, Peter of Aragon was making similar preparations for attacking Sicily and Naples. Peter gave out that he, too, was proceeding upon a crusade, but the French and papal courts divined his intentions, and gave due warning to that of Naples.

Charles had raised an enemy amongst his own subjects more active and deadly than any kingly rival. This was John of Procida, a Sicilian noble, a partizan of the house of Hohenstauffen, and who had suffered confiscation and exile on that account. This man never rested, even during the years of Charles's greatest triumph and power, from exciting disaffection towards him. For this purpose he visited Sicily to form a league amongst the nobles and people of the island against the French. He undertook to negotiate with Genoa, with Venice, and with the pope himself, a league for that purpose. He journeyed even to Constantinople, represented to the emperor Palæologus the designs of Charles, and succeeded in procuring for the king of Aragon a subsidy from the Greek. Peter fitted out a powerful fleet. But an accident in the mean time set fire to that train of disaffection and rebellion which John of Procida had prepared in Sicily.

It was on Easter Monday, in the year 1282, a day consecrated in Catholic countries to a mixture of gaiety and religion, that the citizens of Palermo set out according to custom to hear vespers at the church and village of Monteleale, not far distant. The French soldiers and authorities unsuspectingly joined the procession, and, according to their custom, did not refrain from taking liberties with the young females whom they met or whom they accompanied. One Frenchman, more bold than the rest, under pretence of searching for arms, forbidden to a Sicilian, seized a young girl, and thrust his hand into her bosom. The betrothed of the girl instantly pierced the Frenchman with his own sword. This act was a signal; it corresponded so fully to the intentions and feelings of all present, that the cry of 'Death to the French' ran from mouth to mouth. The deed accompanied the word, and every Frenchman in the procession was assassinated, whilst the vesper bell was still sounding. Excited by blood, the assassins rushed back to Palermo to complete their massacre. Not a Frenchman, save one, escaped: all, to the number of 4000, were butchered; and even Sicilian women, who had married Frenchmen, suffered the same fate, in order that the progeny of the hated strangers might be eradicated from the island.

This massacre, notorious under the name of the *Sicilian Vespers*, was of course the signal of revolt. John of Procida hastened to Peter of Aragon, who after some delay landed in Sicily, and assumed the title of its monarch. His admiral, Roger de Loria, sailed for Messina, to which

place Charles had laid siege, and experienced no difficulty in capturing Charles's fleet, and defeating all his projects of vengeance. The Angevin prince, in despair, acknowledged these disasters as the just judgment of Providence, and only prayed that his inevitable ruin might not at least be precipitate. His anger against his competitor was not the less outrageous. Despairing or impatient of the tedious method of warfare, Charles challenged Peter of Aragon to single combat; and Peter, whose object was to gain time, accepted the challenge. Bordeaux was fixed on as the place of combat, which was to take place between the monarchs in person, each supported by a hundred knights; and it was solemnly agreed on, that Sicily was to be the prize of the victor. On the day appointed, the 15th of May, 1283, Charles of Anjou appeared at the head of a hundred knights, whilst his brother king Philip the Hardy of France, approached with an army. Peter, however, demurred. He complained of the presence of a French army, of the insecurity of the place of rendezvous, not guaranteed, as was agreed on, by Edward of England. The king of Aragon, therefore, either did not make his appearance, or appeared but for a moment to make his protest; and instantly retreated to Spain. Thus the challenge of Charles served, as might have been expected, to delay, rather than hasten, a decision.

Charles now set about collecting a new fleet and forces in Provence, to which the pope contributed, as usual, the promise of an indulgence, and the sacred name of a crusade. But whilst thus engaged in recruiting, the fleet which he already possessed at Naples was defeated by Roger de Loria, and his son, who commanded it, was taken prisoner. Charles hastened to repair this fresh disaster; but in vain. The vigour of his character, as well as of his cause, was gone; and whilst endeavouring to muster ships and form a junction between his fleets, Charles of Anjou died at Foggia in the kingdom of Naples, at the age of seventy-five years, in the early part of 1285. Villani, the Florentine historian, has sketched his character minutely, calling him 'sage, severe, and magnanimous, much dreaded, more famed than any prince for royal dignity, of few words, but great activity, sleeping little, laughing never, and taking no pleasure in mimes or poets, or courtesans.' Charles of Anjou had, in fact, many great qualities; and no prince certainly had ever greater opportunities. Had he made the most of them, he might perhaps have founded an empire in Italy. His reign, however, not only destroyed his own hopes of such an achievement, but that of his countrymen ever after. Henceforth the hatred borne to the French by the Italians was greater than the hate borne by them to the Germans, who have ever since preserved, with the exception of a few intervals, their predominance in the peninsula.

The posterity of Charles of Anjou continued, notwithstanding, to fill for a time the thrones of Naples and also that of Hungary. It is rather as monarchs of these countries, than as counts of Anjou, that their history is to be read or written, since of course they had become utter strangers to this province, and to France itself.

In consideration of this, king John of France reunited Anjou to the crown, giving it soon after in appanage to his son, Louis, who thus commenced the third house of Anjou. The county was elevated into a duchy, by an ordinance of John, in 1360, and Louis is thus the first of the ducal house. He was born in 1339, was taken prisoner with his father at the battle of Poitiers, and remained long in England. Wearied at length with captivity, he fled from that country, and refused to return, notwithstanding all the persuasions of John, who entreated him to keep his parole and return. After the death of king John, the duke of Anjou was entrusted with many commands by his brother Charles V., in all of which he displayed rapacity and cruelty. The title of Anjou seemed contagious in conveying these qualities. Still Charles at his death appointed Louis regent of the kingdom, who made use of his power to further his own personal interests. Instead of consulting the prosperity of France, the regent sought to amass wealth for the purpose of afterwards conquering the kingdom of Naples, to which Jeanne, the heiress of the last house of Anjou, had given him a title by adoption. The pope, as usual, seconded the attempt of the French prince, and Louis was accordingly crowned king of Sicily and Jerusalem at Avignon in 1362. He then led his armies to the conquest of Naples, but they perished, as Louis did himself, by disease, in 1364.

His son, Louis II., duke of Anjou, was also crowned

king of Sicily by the pope. Three times he essayed to render himself master of Naples, and on one occasion he defeated his rival, Ladislas, in battle. But all his efforts, united to the papal support, were unable to lessen the repugnance of the southern Italians to the French. Far from conquering Naples, he was unable to defend Anjou from the English, who continually ravaged it. He died in 1417.

Louis III., son of the last duke, attacked Naples, in 1420, with some success, but was beaten off by his competitor, Alphonso of Aragon. In 1423, he renewed the attempt, aided by the duke of Milan. The armies of this prince brought Louis in triumph to Naples, but while he was victorious in Italy, Alphonso was ravaging Provence. Louis, however, still persisted in prosecuting his conquest; he laid siege to Tarentum, but died soon after at Cosenza, in 1434.

He was succeeded, not so much in his kingdom as in his claim, by his brother René, surnamed the Good king René, who not only failed in recovering the Italian empire of his family, but was dispossessed of Anjou itself by Louis XI. [See RENÉ']

From the days of Louis XI. the title of Anjou lay dormant, whilst the sovereigns of France themselves prosecuted their claims to Italian dominion, as heirs of the Angevin princes. With Francis I. these hopes expired. His successor, Henry II., bestowed the duchy of Anjou upon his third son, who bore this title when elevated to the throne of Poland. As this prince, however, succeeded to the throne of France, he is better known under the name of Henry III., to which the reader is referred. Henry's younger brother, at first duke of Alençon, succeeding to the title of Anjou, is best known under this latter name.

This prince was born in 1554, and was first christened Hercules, a name that was afterwards changed for that of Francis at confirmation. He had the small-pox very young, and was so 'horribly spoiled' that his mother, Catharine de Medicis, took a dislike to the boy, and sent him to Amboise to be educated apart from his brothers and from the court. Having once visited this place, Catharine spoke of him as 'a little *moricaud* (black), who had nothing but war and tempest in his head.' The young prince naturally returned his mother's aversion; and this may have been the original cause of his liberality of opinion, since it threw him into the confidence and friendship of Catharine's enemies, the Huguenots. The duke of Alençon, such was the title he first bore, was much attached to Coligny, their leader, who exerted himself to draw the young prince to his party. According to queen Margaret's Memoirs, the Huguenots had promised her brother Francis, at a very early epoch, to procure for him the principality of Flanders; and when the negotiations between Elizabeth and the first duke of Anjou were growing hopeless, Coligny mentioned to Walsingham, how much more desirable a husband for Elizabeth the duke of Alençon would prove than his brother. The idea was acted upon afterwards; and the duke of Montmorency in person proposed prince Francis as a husband to the queen of England. She wrote over for an account of his person, which was far from favourable. He was too young, it seems, and too small; and though Catharine de Medicis wrote to remind Elizabeth that heroes were of small stature, Du Guesclin himself, the famous constable, being no more than four feet high, and added in excuse of her son's youth, that his beard was beginning to grow, still Elizabeth showed herself more politic than amorous. The massacre of St. Bartholomew, which soon after occurred, created a distance and aversion between the two courts.

On that occasion the duke of Alençon maintained an honourable part. He so openly expressed his abhorrence of the event, and his admiration for Coligny, that he became as much an object of suspicion as any of the Huguenots. He was sent against La Rochelle, as to a school of martial orthodoxy, where he was nearly killed by a shot from the ramparts. Returning to court, he found himself more a captive than anything else, with Henry of Navarre, the future Henry IV., as his companion. Rivalry in their amours prevented the princes from agreeing perfectly, but the duke of Alençon not the less joined in all the projects and conspiracies of the Huguenots. They now conceived other hopes for him. Charles IX. was lingering under a mortal malady; his brother, the next heir, was in Poland. The Protestants hoped to elevate the duke of Alençon to the throne in his place; thus exchanging a monarch whom they detested, for one who favoured their own opinions.

A plot was accordingly formed. A Huguenot insurrection was to take place; the duke of Alençon, Henry of Navarre, and the prince of Condé were to fly secretly from court and join it. The queen herself was to be surprised at St. Germain. This promising scheme utterly failed through the perfidy and weakness of him whom it was designed chiefly to benefit. The duke of Alençon, instead of escaping at the appointed moment, hurried to his mother's feet, and confessed the whole affair. The consequence was the arrest of all who were implicated, and the failure of the enterprise. To render the act more base on the part of Alençon, the whole weight of vengeance fell upon his confidants and followers.

Whatever had been the motive which had influenced the duke of Alençon in betraying his friends, he reaped no advantage from the act. Catharine of Medicis took him and Henry of Navarre with her, when, after the death of Charles IX., she went to welcome Henry III. on his return from Poland. She presented them as prisoners to the new king, who at first seemed severe, but inflicted no punishment. The duke of Alençon continued at court, the rallying point of opposition to Henry; opposition, however, which was as trivial as the character of the two princes.

At length the duke of Alençon, becoming reconciled to the Huguenots, who once more trusted him, entered into more manly schemes of vengeance. He escaped from court in the autumn of 1575, and placed himself at the head of the armies raised by the reformers. The king had not the vigour requisite to march against his brother; and he knew, perhaps, that under such a chief his enemies were not much to be dreaded. Instead of an army, Catharine surrounded her person with a score of beauties, and proceeded to entice the mutinous princes to colloquies, where seduction was the means of negotiation. A truce first, and a peace afterwards, were the fruit of a year's show of hostility. The duke of Alençon secretly proposed to desert his party once more; but the Huguenot chiefs insisted upon favourable terms, which they obtained, in name at least, in 1576. The duke, on his part, obtained advantages equally favourable; letters patent being soon after issued, which gave him the duchies of Anjou, Touraine, and Berri.

In this arrangement, however, the negotiators on both sides may be said truly 'to have reckoned without their host.' The Catholics, disgusted with the weakness of the monarch, formed the *league*, which soon rendered the articles of peace null. The Protestants on their side, little trusting to empty promises, kept armed and in an hostile posture, and Henry of Navarre was now rising amongst them to fill the place of honour that the now duke of Anjou had ceded. War, in consequence, recommenced, and, strange to say, the duke of Anjou himself appeared in command of a Catholic army.

In perusing the history of these times, it is difficult to say where most fickleness is found, whether in princes, or in the people. After having turned against the Huguenots, and even sacked one of their towns, the duke of Anjou was still trusted by them, and when overtures were made to him by the malcontents of the Low Countries, several of the leading Protestants forsook Henry of Navarre for the banner of the duke of Anjou. Sully himself was of this number. Henry was afflicted by this desertion, but remarked, that Anjou had 'so little courage, so little address, and so false a heart, that he would soon throw away all the advantages that fortune placed at his command.'

Catharine of Medicis and Henry III., reconciled to their son and brother, now laboured to procure for the duke of Anjou those very prizes that Coligny had before sought to give him—the sovereignty of Flanders, and the hand of queen Elizabeth. When the States asked for French aid, every facility and support was given by the king towards the raising of an army for his brother; at the head of this the duke of Anjou marched against don John of Austria. He had at first some success, but not being so well received by the Flemings as he expected, his career of conquest was suspended. In pursuance of the other part of his scheme, he had deputed to Elizabeth his envoy, Simier. The French manners and gallantry of this personage quite won the English queen, who threw off much of her habitual prudery, and began to entertain serious thoughts of marrying Anjou. She made him a present of a considerable sum of money, and went so far that articles of marriage were drawn up. Fortune seemed on all sides to favour the duke.

He was elected sovereign of the Netherlands in 1581, and took possession of Cambray in spite of the prince of Parma. Thus, crowned with honour, the duke hastened over to England to terminate in person his suit with the queen. Nothing could be more brilliant or warm than his reception. When he stooped to kiss the hand of Elizabeth, she substituted the English custom of offering the mouth. Agreements of the closest alliance were concluded, and in token of her affection she gave him a ring, which she placed upon his hand in public. In the midst of all this graciousness, however, clouds began to arise. Leicester and other counsellors were jealous and averse; the people of London grew clamorous in their dislike of a popish prince, a dislike much increased by the conduct of the French, which was turbulent and licentious. One of them drew his dagger and pursued a foe into the private cabinet of the queen; and nearer acquaintance enabled both Elizabeth and the English to form a true judgment of their proffered allies. The queen at length hesitated. The habitual caution of her character got the better of her temporary whim; and at the end of three sleepless nights she sent for her suitor in order to put an end to his hopes by demands that amounted to a refusal. She wanted Calais, she could not tolerate his religion, and not satisfied with her own arguments, she called in Hatton to repeat them to the prince. The duke naturally railed at the inconstancy of women, especially of the English, and was about to depart instantly; but Elizabeth did all to soften his disappointment and her own. She detained him for months, feasted, and promised, and avoided him; beguiling both him and, perhaps, herself with hopes of a union which her prudence could never permit.

At length the duke of Anjou took his departure from England to govern the Netherlands. Bred up at the French court, however, he had no idea of a sovereign whose authority was to be shackled in any way, either by the institutions of a country, or even by his own most solemn oaths. The son of Catharine of Medicis was not to be thus restrained. The duke of Anjou appeared to assume the sovereignty of the Netherlands with the determination to usurp despotic authority, and trample on the citizens as well as the family of Orange.

Unaccustomed to the free display of popular and personal independence, he mistook the rival influence of the prince of Orange, and of the citizens in the several towns, for insults to his dignity and treason to his rights. Instead of making use of such means to overcome them, as were allowed and might have succeeded with the Flemings, he formed a conspiracy similar to those which disgraced the annals of France at that epoch. He proposed, in fact, to seize the Flemish fortresses by means of his soldiers, and thus to bridle the turbulence of an independent people. But he mistook the character of the people. The Flemish citizens mastered his soldiers everywhere; the people of Antwerp especially made a successful resistance, and not only Anjou himself, but the French were expelled by the united force, and amidst the general execrations of the country. It was thus that another prince of Anjou had caused his countrymen first to be detested, and then driven from Italy. The name is linked with the chief political failing and chief disasters of the nation.

From this hour the duke of Anjou sunk into insignificance. He was too low in fortune and in character to mingle, or to have influence in any party, or in any struggle. He expired soon after, in 1584, at Château Thierry, bequeathing to his royal brother his creditors, 'whose substance and tears and suffering,' they being chiefly his own servants, 'he dragged with him to the grave.' Such were the words of his testament. His brother Henry, in lieu of paying the 300,000 crowns, to which his debts amounted, preferred expending 200,000 on a pompous funeral.

ANJOUAN. [See ANZOUAN.]

ANKER, a measure of wine and spirits, particularly of the latter, formerly in use, containing 10 old wine gallons, or 8½ imperial gallons, that is, 2310·62 cubic inches. This measure is also in use in various parts of Europe, and the comparison between the ankers of different places is in the table underneath. A full account of the other measures connected with it may be found in Kelly's *Cambist*.

ANKARSTROEM (JOHN JAMES), a Swede, born in 1759, of a family then recently ennobled. He was placed in the king's guards as ensign, but left the service when only twenty-four years of age, having obtained the honorary or brevet rank of captain in the army; he then retired to his patrimonial estate in the country. He seems to have been early dissatisfied with Gustavus III. on account of the change that king had effected in the constitution of the country. At the Diet of 1772, Gustavus curtailed the power of the senate, or high nobility, who were till then possessed of an almost unlimited authority, and he was in this attempt supported by the other three orders, especially by the citizens and the peasants, who were tired of the irresponsible oligarchy of the senators; but the king having thus wrested the power from the nobles, took it to himself, and ruled almost absolutely. This caused as much dissatisfaction among the popular estates as his former measures had caused among the high nobility. (See **GUSTAVUS III.**) Ankarstroem, who did not himself belong to the high nobility, seems to have sympathised more in his political discontent with the popular orders against the absolute power attained by the king. He was accused of having spoken against the king before an assembly of peasants, and although the charge could not be proved against him, he was confined first in the castle of Wisby, in the island of Gothland, and afterwards transferred to other fortresses: he was, however, at last released. Ankarstroem was present at Stockholm in 1789, when the king, after suppressing the senate and arresting the most refractory members of the nobility, came in person to their Chamber, which he had previously surrounded with his soldiers in order to force them to assent to his innovations. Ankarstroem spoke with great vehemence, even in the king's presence, against the violation of the constitution, and his speech made a considerable impression on the assembly. The execution of colonel Hæstko, an officer of the army of Finland, who had opposed the king's orders and refused to act on the offensive against Russia, on the ground that the war had not been sanctioned by the estates of the kingdom, seems to have filled the measure of Ankarstroem's resentment against Gustavus. It appears that it was then that he first thought of murdering the king, without being connected with any other conspirators; but falling in afterwards with several disaffected nobles, among others counts Horn and Ribbing, he communicated to them his purpose, and they encouraged him in his determination. They first tried to seize the king at Gefla, where he had convoked the Diet for 1792, but being thwarted in their design, they at last determined to strike the blow at a masked-ball where the king was to be present, on the 16th March, 1792. Count Horn agreed that he should point out the king among the crowd to Ankarstroem. Gustavus received an anonymous note warning him not to go to the ball, but he disregarded the advice, and went in a domino dress. As he was pacing down the hall, leaning on count Ersen's arm, Horn, followed by Ankarstroem, accosted the king, saying, "Good day, fair mask." At these words, which were the signal agreed upon, Ankarstroem fired a pistol loaded with two balls, and dangerously wounded the king in the thigh. He was not then recognized, and went out of the hall unmolested. After the assembly had dispersed, a pistol and a dagger were found on the floor. The armourer whose name was on them, deposed that he had lately sold them to Ankarstroem, who was then arrested in his house; on his first examination he was subjected to the torture, but he was afterwards tried before the ordinary tribunals. He acknowledged his crime, but denied having any accomplices. He, however, confessed that several persons knew of his determination. He was condemned to be publicly whipped with rods for three successive days, and then to be beheaded after having his right hand cut off.

The king had expired a few days after receiving the wound. Ankarstroem went to the scaffold with resignation; he was then only thirty-three years of age. Many other persons were arrested and tried; two of them destroyed themselves, but none were executed. Counts Horn and Ribbing, and colonel Lilientholm, were banished for life. The report of Ankarstroem's trial was published at Stockholm.

ANKLAM, a strong town of Hither Pomerania, in Prussia, lying on the river Peene, twenty miles south-east of Greifswald. Its port enables it to carry on a brisk intercourse with other countries, and it possesses considerable manufactures of woollens, linens, leather, and tobacco. By the census of 1831, its population appears to have amounted to 6286.

Anklam is the capital also of a circle of the same name in the government of Stettin, which circle contains 22,500 inhabitants.

ANNA BOLEYN. [See **BOLEYN.**]

ANNA COMNENA, the daughter of Alexius Comnenus I., emperor of Constantinople, born Dec. 1, 1083, best known as the author of the *Alexiad*, a work written in Greek, containing the history of her father's life. She was the favourite child of Alexius, and her talents were sedulously cultivated by an education comprehending the study of eloquence, poetry, mathematics, natural science, and the philosophy of Plato and Aristotle (see her preface to the *Alexiad*); and the voice of loyal admiration soon pronounced that her acquirements surpassed those of her most skilful masters. She married Nicephorus Bryennius, a man of high birth, and of high literary attainments. Presuming on parental partiality, she solicited Alexius to name her husband for his successor, to the exclusion of her brothers, John and Isaac; and in this attempt she was assisted, if not mainly prompted, by her mother, the empress Irene. Pressed on this subject, the dying emperor uttered some allusion to the vanities of the world, which drew from Irene the unfeeling speech, 'You die, as you have lived, a hypocrite.' Alexius died Aug. 13, 1118, and John Comnenus, the lawful heir, possessed himself of the royal signet, and became master of the palace, and of the empire. Disappointed ambition drove Anna to conspire against her brother's life. All was prepared, but fear or remorse induced Bryennius to absent himself at the moment of action; and in her passionate disappointment the princess exclaimed, that 'nature had mistaken the two sexes, and endowed Bryennius with the soul of a woman. On the discovery of the meditated treason, the life and fortune of Anna became justly forfeited. Her life was spared by the clemency of John, the best and greatest of the Comnenian princes; but her palace and treasures were confiscated, and bestowed upon a friend of the emperor who proved how well he deserved favour, by declining the gift, and interceding for the criminal. The guilty princess escaped with no further punishment than a forced retirement from the world, and exclusion from the splendour and intrigues of a court. Thus thrown on herself, she relieved the heaviness of her solitary hours by composing the *Alexiad*, a history of her father's life and reign in fifteen books, from 1069, twelve years before he ascended the throne, to his death in 1118. She completed it in 1148, and died in the same year. The *Alexiad* is distinguished by an air of filial piety both as regards the person and the fame of Alexius. Aware that she was exposed to the suspicion of partiality, she professes to have compared her own impressions, drawn from the intimacy of relationship, with all that had been said and written by the most competent judges. She describes herself as having lived in melancholy solitude for the last thirty years, without hope, and without fear, forgotten by the world and forgetful of it, and declares truth to be more dear to her than even her father's memory. But the internal evidence afforded by the style does not confirm these high pretensions. The book is overloaded by rhetorical display, and by the affectation and misplaced obtrusion of science. Individuality of character is lost in indiscriminate panegyric, and the likeness is rendered suspicious by the barefaced flattery of the portrait. The most curious and important part of Anna's history, as of her father's reign, is that which relates to the first crusade. It is often at variance with the Latin authorities, and on no point more so than on the character of Alexius. The comparison of these conflicting statements, with due allowance for the prejudices of each party, affords some chance of approximating to the truth.

The *Alexiad* forms a part of the collection of Byzantine

historians. The first complete edition of it was published at Paris, 1651, by the Jesuit, Poussines, with a Latin translation and glossary. It has been translated into French by the president Cousin. A series of valuable notes on it, by the learned Du Fresne, will be found at the end of the *Historiæ* of John Cinnamus, containing an account of the reigns of John and Manuel Comnenus. There is a German translation of the *Alexiad*, in the historical collection of F. Schiller, Jena, 1790.

ANNA IWANOWNA, empress of Russia, was the second daughter of the czar Iwan or John I., the elder brother of Peter the Great, and for some time his associate on the throne. She was born on the 8th of February, (O.S.) 1694. In 1710 she was married to Frederic William, duke of Courland, who died in 1711. On the death of the emperor, Peter II., on the 29th of January, 1730, without issue, it was pretended by the Dolgorouckis, who for some time had been the ruling favourites of the late monarch, that he had left a will appointing their sister, the princess Catherine Dolgoroucki, to whom he had been betrothed, his successor. The project of raising that lady to the throne, however, miscarried, in consequence, it is said, of a want of union among the heads of the powerful family by whom it had been contrived. The duchess dowager of Courland was elected by the council of state, the senate, and the principal military officers then at Moscow, who assembled in the Kremlin immediately after the emperor's death for the purpose of determining who should wear the crown. The object of the persons who composed this meeting unquestionably was to reduce the government of Russia to a limited monarchy, or rather, perhaps, to an aristocratical form. They did not, however, take their measures with either the good management or the boldness requisite for so great an undertaking. For the present they deemed it necessary to name a successor to the late emperor, and the duchess Anna was unanimously fixed upon, being, it is believed, indebted for this preference to her residence at so great a distance from the capital as would give the projectors of the revolution time to strengthen themselves in their position before she could make her appearance. Her elder sister, the duchess of Mecklenburgh, who was then in Moscow, was passed over on the pretence that she had forfeited her claim to the throne of Russia by having married a foreigner. The princess Elizabeth also, the daughter of Peter the Great, who afterwards became empress, was in the palace; but although her surgeon, on hearing of the death of the emperor, ran immediately to her chamber, and pressed her to present herself to the people and assert her title to the crown, she could not be prevailed upon to leave the room.

The Empress Anna, however, was not simply called upon to assume the vacant throne. Seven articles or conditions were attached to the invitation that was sent to her, to which she was required to give her consent before being permitted to reign. These conditions went to subject the crown entirely to the power of the nobility; and it was possibly calculated by their authors that Anna would at once reject them. To take her by surprise, all those present at the meeting were forbidden, under pain of death, to reveal to any one what had been done. One individual, however, the count Jagouzinski, defeated this scheme by sending a courier to the duchess, who, in spite of the guards placed on the road, contrived to reach Mittau, where she was, just in time to make her acquainted with what had taken place before the deputies from the council of state arrived. The advice sent by Jagouzinski was, that she should unhesitatingly promise whatever was asked of her, and leave the rest to him. She followed this counsel, and immediately set out for Moscow.

She arrived in the capital on the 20th of February. For a few days she dissembled her designs. But on the 8th of March, having previously made all the necessary arrangements to secure success, she assembled the council of state and the senate in the palace, at all the avenues of which her guards had been stationed with their pieces loaded, and displaying before them the papers which she had signed, declared her promises annulled as having been fraudulently obtained, and announced herself empress and autocrat of all the Russias, with the full authority and prerogatives which her ancestors had enjoyed. The revolutionary party, struck with surprise and consternation, acquiesced without an attempt at resistance; while by the people generally the intelligence of what had taken place was received with tumultuous rejoicings. Thus terminated the last of the only two at-

tempts to limit the royal power which are recorded in the history of Russia; the former, which was equally unsuccessful, being that which was made in 1613, on the election of the czar Michael Federowitz, the founder of the reigning house. The banishment of the Dolgorouckis, the dismissal of the council of state and the nomination of another, and the remodelling of the army, quickly followed these events. In January, 1732, the empress left Moscow, and took up her residence at Petersburg.

One of the first acts of the new reign, after these domestic matters had been arranged, was to enter into a treaty with Denmark, with which power Russia had been in a state of hostility since the time of Peter the Great. Another treaty was also soon after made with Persia, by which several of the conquests of Peter the Great, which had been found only sources of expense to Russia, were restored to that power. About the same time an embassy arrived at Petersburg from China, being the first which had ever been sent from that country to any European court.

This peaceful policy, however, was soon interrupted. On the 11th of February, 1733, Augustus II. king of Poland died suddenly at Warsaw, and the three powers of France, Austria, and Russia, were immediately embroiled in a contest respecting the succession to the vacant throne. France supported Stanislaus Lescinski, who had formerly been king, but had been deprived of his crown by the result of the great battle of Pultowa, in 1709; and the two other powers joined to bring about the nomination of the elector of Saxony, the son of the late sovereign, afterwards Augustus III. Before the end of the year Russia had marched a body of 20,000 troops into Poland; and on the 22d of February, 1734, the count Lacy, who commanded them, sat down before Danzig, which held out for Stanislaus. Field-marshal Munich soon after arrived and took the command; under whose conduct, notwithstanding all the efforts of the French to raise the siege, the town was forced to surrender on the 30th of June. Count Lacy was the following year sent into Germany to assist the emperor Charles VI. with a body of 10,000 men, who advanced as far as the Rhine, and were the first Russian troops which had ever been seen in the centre of Europe.

In the course of the same year an expedition was sent to the Crimea against the Tartars inhabiting the steppes between that peninsula and the Ukraine, who had long been in the habit of making incursions into the Russian territory. This led, in 1736, to hostilities with Turkey. The war was conducted by field-marshal Munich; and the principal operations of the first campaign were the capture of Perecop on the 1st of June, after a short attack, and of Azof on the 29th, after a siege of three months, by count Lacy. Various other places of less importance were also forced to surrender; and the Turks and Tartars were beaten wherever they showed themselves. The operations of the next season were on a larger scale. On the 13th of July the town of Ockzakow surrendered at discretion to the Russian troops after a bombardment of two days, the victors, however, being indebted for their speedy success to a fire which broke out in the town and threatened its destruction. A subsequent attempt of the Turks to recover the place was unsuccessful, after having cost them 20,000 men. In the course of this year also, Austria, in conformity with a treaty which had been concluded between the two powers, came to the aid of Russia in this new war. The operations of the emperor's troops, however, were as unfortunate as those of the Russian army were the reverse; and after the war had been continued in these circumstances for nearly two years longer, in the course of which time the most important event was the capture by marshal Munich of the town of Chockzim, on the 31st of August, 1739, Austria was compelled, on the 18th of September, in the same year, to conclude the treaty of Belgrade, by which she gave up Belgrade and Servia to Turkey; and in consequence Russia, whose troops had now passed the Pruth, was also a few weeks after obliged to make peace, and to restore to the Turks Ockzakow and all her other conquests, except Azof, the fortifications of which, however, it was stipulated should be destroyed. The year before the question of the Polish succession had been settled in favour of Augustus by the treaty of Vienna, concluded on the 18th of September.

The peace with Turkey was proclaimed at Petersburg on the 26th of February, 1740. Towards the end of September the empress was taken ill, and although no appre-

hensions were entertained at first, the attack soon assumed a serious form. When she found herself in this state, she proceeded to arrange the succession; and on the 18th of October, the prince Iwan, the son of Anthony Ulrick, duke of Brunswick, and the grandson by his mother of the empress's elder sister Catherine, being then a child only three months old, was publicly declared grand duke of Russia, and successor to the throne. This matter having been settled, the empress died on the 28th of the same month.

The empress Anna had a considerable share of the ability which has long distinguished the imperial family of Russia. The manner in which she conducted herself on coming to the throne showed great decision of character, and the success with which the affairs of the empire were managed throughout her reign may be taken as a general proof of her superior talents and judgment. She was not, however, a very popular sovereign, owing principally to the many acts of oppression which were perpetrated in her name by her favourite Biron, as he called himself, his true name being *Bieren*, a minion whom she had raised from a low condition to be gentleman of the chamber in her court at Courland, and whom, having brought him with her to Russia, she eventually forced the nobility of Courland to elect as their duke. Biron was really the ruler of Russia during the whole of the reign of Anne. On her death-bed, she also appointed this person regent of the empire, till her successor should attain his eighteenth year; but her signature to the paper, by which this disposition was made, is said to have been obtained partly by fraud and partly by force. Biron did not long enjoy his dignity, having before the end of the year been seized by a body of conspirators, and soon after banished to Siberia. In one important respect, Anna did something to reform the gross habits of the Russian court, namely, by discountenancing and putting down as far as she could the drunkenness in which both men and women had been accustomed to indulge. Only one nobleman, prince Kourakin, it is said, had her permission to drink as much as he pleased. The empress also, although there was a great deal of deep play at court, never would herself play for money. Her favourite amusements were music and theatrical entertainments. It was in her reign, in 1736, that the first Italian opera was played at Petersburg. In 1739, the famous palace of ice was built by her directions, on occasion of the marriage of prince Galitzin with a peasant girl, the newly-wedded pair, as a part of the frolic, being compelled to pass the night in one of the rooms, all the furniture of which, including the bed in which they slept, was of the same material with the building itself. A full and excellent account of this reign, and especially of the military events by which it was distinguished, has been given by the baron de Manstein in his *Memoirs of Russia from 1727 to 1744*. An English translation of this work from the baron's manuscript was published in 1770, under the superintendence of David Hume.

ANNABERG, a town in the Erzgebirg (ore-mountain district) of the kingdom of Saxony, 2800 feet above the level of the sea, containing 5500 inhabitants. It has considerable manufactures of cotton-lace, bobbinet, and ribbons, and trades in silver, tin, cobalt, and marble, which it receives from the neighbouring mines and works. Annaberg has a handsome church, orphan asylum, and high school. It is about thirty-six miles south-west of Dresden.

ANNAGOONDEY. [See **BISNAGHUR**.]

ANNAH, a town on the right bank of the Euphrates, about 34° 15' N. lat., 41° 50' E. long., where the river makes a small bend to the north-east. Opposite the town is a line of cultivated islands. The town consists of a long, narrow, winding street, on the bank of the river, and at the base of the hills which here line the Euphrates. This narrow strip is occupied by the town, and has numerous date groves, which overhang the clay buildings. The town contains about sixteen mills, some for irrigating the grounds and others for grinding wheat. Annah contains the remains of four ancient castles, one of which is on the largest island; there are two mosques, and a beautiful minaret, eighty feet high. There is a manufactory of coarse cloth for Arab cloaks; much wool is prepared, and some cotton. The number of houses is about 1800. On the left, or west bank, the hills rise abruptly, and are without wood: the boat-passage is along this bank as far as the last and largest of the islands, opposite to which the modern town terminates, and the remains of old Annah, or the Anatho of Isidore, commence, covering the island and extending east-

ward for two miles farther along the left bank. Nitre is procured at Annah, or near it; and Tavernier says, that chalk is dug in many places. Annah has apparently always been a town of some importance from its position in the desert, and serves as a resting-place between Bagdad and Aleppo, and between Bosrah and Aleppo.

From Annah to Aleppo is a journey, at the ordinary rate of travelling, of about 106 hours, or 15 or 16 days; from Annah to Bagdad, across the desert of Mesopotamia, 54 days. (*Itinerary of Isidorus Characenus*, in Hudson's *Minor Greek Geogs.*; Captain Chesney's *Report on the Euphrates*; *London Geog. Journ.*, vol. iii.)

ANNALS, in Latin *Annales*, is derived from 'annus,' a year. Cicero, in his second book, *On an Orator (De Oratore*, chap. xiii.) informs us, that from the commencement of the Roman state down to the time of Publius Mucius, it was the custom for the Pontifex Maximus, or high priest, annually to commit to writing the transactions of the past year, and to exhibit the account publicly on a tablet (*in albo*) at his house, where it might be read by the people. Mucius was Pontifex Maximus in the beginning of the seventh century from the foundation of Rome. These are the registers, Cicero adds, which we now call the *Annales Maximi*, the great annals. It is probable that these annals are the same which are frequently referred to by Livy under the title of the *Commentarii Pontificum*, and by Dionysius under that of the *ἱστορίαι τῶν ποιητῶν*, or *Sacred Tablets*. Cicero, both in the passage just quoted, and in another in his first book *On Laws (De Legibus)*, speaks of them as being extremely brief and meagre documents. It may, however, be inferred from what he says, that parts of them at least were still in existence in his time, and some might be of considerable antiquity. Livy only says that most of the contents of the Pontiffs' Commentaries were lost at the burning of the city after its capture by the Gauls. It is evident, however, that they were not in Livy's time to be found in a perfect state even from the date of that event (A.U. 363); for he is often in doubt as to the succession of magistrates in subsequent periods, which it is scarcely to be supposed he could have been, if a complete series of these annals had been preserved.

The word annals, however, was also used by the Romans in a general sense; and it has been much disputed among the critics what was the true distinction between annals and history. Cicero, in the passage in his work *De Oratore*, says, that the first narrators of public events, both among the Greeks and Romans, followed the same mode of writing with that in the *Annales Maximi*; which he further describes as consisting in a mere statement of facts briefly and without ornament. In his work *De Legibus* he characterizes history as something quite distinct from this, and of which there was as yet no example in the Latin language. It belongs, he says, to the highest class of oratorical composition (*opus oratorium maxime*).

This question has been considerably perplexed by the division which is commonly made of the historical works of Tacitus, into books of annals, and books called histories. As what are called his *Annals* are occupied with events which happened before he was born, while in his *History* he relates those of his own time, some critics have laid it down as the distinction between history and annals, that the former is a narration of what the writer has himself seen, or at least been contemporary with, and the latter of transactions which had preceded his own day. Aulus Gellius (*Noctes Atticæ*, v. 18) has stated this doctrine, which, after his manner, he has endeavoured to support by a reference to the etymology of the word history, from the Greek *ἱστορίαι*, properly to inquire in person.

It must be evident that this is quite an unfounded notion. Without attempting to define at present what history properly is, which will be more conveniently done under the word itself, we may venture to assume, that it does not mean merely memoirs of events by contemporaries. And it is equally clear that there is nothing in the term annals which should make it exclusively applicable to accounts of past ages. We doubt if Tacitus himself ever gave the name of histories to any of his writings. If he gave either work a title at all, more probably he gave to both that of annals only. We rather think it will be found, that wherever he mentions his historical writings, he refers to them by this name. It is, at any rate, by no means certain that the common division either originated with him, or was even recognised by others of his own age.

Tacitus has himself in one passage intimated distinctly what he himself understood annals to be, as distinguished from history. In his *Annals* (commonly so called), lib. iv. cap. 71, he states his reason for not giving the continuation and conclusion of a particular narrative which he had commenced, to be simply the necessity under which he had laid himself by the form of composition he had adopted of relating events strictly in the order of time, and always finishing those of one year before entering upon those of another. The substance of his remark is, that 'the nature of his work required him to give each particular under the year in which it actually happened.' This, then, was what Tacitus conceived to be the task which he had undertaken as a writer of annals, 'to keep everything to its year.' Had he been writing a history (and in the instance quoted above, he insinuates he had the inclination, if not the ability, for once to act the historian), he would have considered himself at liberty to pursue the narrative he was engaged with to its close, not stopping until he had related the winding up of the whole. But remembering that he professed to be no more than an annalist, he restrains himself, and feels it to be his business to keep to the events of the year.

It is of no consequence that on some other occasions Tacitus may have deviated somewhat from the strict line which he thus lays down for himself—that he may have for a moment dropped the annalist and assumed the historian. If it should even be contended that his narrative does not in general exhibit a more slavish submission to the mere succession of years than others that have been dignified with the name of historians, that is still of no consequence. He may have satisfied himself with the more humble name of an annalist, when he had a right to the prouder one of an historian; or the other works referred to may be wrongly designated histories. It may be, for instance, that he himself is as much an historian in what are called his *Annals* as he is in what is called his *History*. In that case all we can say is, upon any interpretation of the words that may be advanced (except indeed the foolish one proposed by Aulus Gellius), that one of the titles is wrong.

In lib. iii. cap. 65 of his *Annals*, Tacitus tells us that it formed no part of the plan of his *Annals* to give at full length the sentiments and opinions of individuals, except they were *signally* characterized either by some honourable or disgraceful traits. In chap. 22 of the treatise on Oratory, attributed to Tacitus, the author expresses his opinion of the general character of the style of ancient annals; and (*Annal*. xiii. 31) he carefully marks the distinction between events fit to be incorporated into annals and those which were only adapted to the *Acta Diurna*. [See *ACTA DIURNA*.]

The distinction we have stated between history-writing and annal-writing seems to be the one that has been commonly adopted. An account of events digested into so many successive years is usually entitled, not a history, but annals. The *Ecclesiastical Annals* of Baronius, and the *Annals of Scotland*, by Sir David Dalrymple (Lord Hailes), are well-known examples. In such works so completely is the succession of years considered to be the governing principle of the narrative, that that succession is sometimes preserved unbroken even when the events themselves would not have required that it should, the year being formally enumerated although there is nothing to be told under it. The year is at least always stated with equal formality whether there be many events or hardly any to be related as having happened in it. In this respect annals differ from a catalogue of events with their dates, as, for instance, the *Parian Chronicle*. The object of the latter is to intimate in what year certain events happened; of the former, what events happened in each year. The history of the Peloponnesian war by Thucydides has the character of annals. The events are arranged distinctly under each year, which is further divided into summers and winters. All political reflections are, for the most part, placed in the mouths of the various commanders on each side.

In the *Rheinisches Museum für Philologie*, &c., ii. jahrg. 2 heft. pp. 293, &c., there is a disquisition by Niebuhr on the distinction between History and Annals, in which he limits the latter nearly as has been done above. But the greater part of the paper is taken up in endeavouring to account for the definition given by Aulus Gellius, which is illustrated in a manner perhaps more fanciful and ingenious than convincing. There is a translation of it in the Sixth

Number (for May, 1833) of the *Cambridge Philological Museum*.

It scarcely need be noticed that the term annals is popularly used in a very loose sense for a record of events in whatever form it may be written—as when Gray speaks of
'The short and simple annals of the poor.'

In the Romish Church a mass said for any person every day during a whole year was antiently called an annal; and sometimes the same word was applied to a mass said on a particular day of every year. (See Du Cange, *Glossarium ad Scriptores Mediæ et Infimæ Latinitatis*.)

ANNAGOONDEY. [See BISNAGHUR.]

ANNAMABOE, or ANNAMABOO, a town with a fort belonging to the English, on the Gold Coast in West Africa. It is ten miles east from Cape Coast Castle, and six miles east from the intervening Dutch fort of Nassau. In Mr. Bowdich's map (*Mission to Ashantee*) it is placed in 5° 5' N. lat. and 5° 40' W. long. The fort of Annamaboe is considered to be the strongest on the coast. It is of a quadrangular form, and is built on a low site close to the shore, the town surrounding it in the form of a crescent, and coming down to the sea on both sides of it. The direction of the coast here, it will be recollected, is nearly due east and west. The fort of Annamaboe is commanded by an officer who holds the next rank to the governor of Cape Coast Castle. According to Captain John Adams, in his *Remarks on the Country extending from Cape Palmas to the River Congo*, (8vo. 1823,) the population of the town then amounted only to 3000 or 4000 persons, most of whom, he says, had become opulent from the trade in gold and slaves, of which this fort had long been the chief mart. Some among them are described as acting by a sort of hereditary right in the capacity of gold-takers to all ships that arrive, that is, of functionaries whose business it is to manage all negotiations and bargains between the traders and the natives, and to be responsible for the quality of the gold, by a per centage on the amount of which their services are paid. Mr. Meredith, however, in his *Account of the Gold Coast*, (1812,) speaks of the place as having been formerly much more populous. In 1807, the inhabitants, who considered themselves as belonging by their position to the nation of the Fantees, took part with them against the Ashantees; in consequence of which both the town and fort were attacked by a vast body of the latter. About 10,000 of the inhabitants of Annamaboe, according to Mr. Meredith, being two-thirds of the whole, were slain on this occasion; and about 2000 more of them took refuge in the fort. The fort was held by a garrison of only about thirty men, and with difficulty withstood the assault of the immense host that encompassed it. A ledge of rocks extends in front of this town a few yards from the shore, which makes, Captain Adams says, a good break-water.

ANNAMOOKA, island of. [See ROTTERDAM.]

ANNAN. [See COCHIN CHINA.]

ANNAN, a town in Scotland, in the former stewartry of Annandale, and in the county of Dumfries, 79 miles S. of Edinburgh, 15½ E. by S. of Dumfries, and 20½ W. by N. of Carlisle, 54° 59' N. lat., 3° 14' W. long. of Greenwich.

The town is situated on the river Annan, not far from where it falls into the Solway Frith. Over this river there was formerly a bridge of five arches, now replaced by a more modern one of three; the river is navigable for vessels of 250 to 300 tons, to within half a mile of the town, and for vessels of 60 tons up to the bridge, forming a good natural harbour. The road from Carlisle to Dumfries runs along the principal street, and there are small lanes or closes leading to the right and left, but the increased size of the place has caused some new streets to be built. The houses are, in general, good; some handsome buildings have been lately erected; and the town is paved, and has a neat and improving appearance. The manufactures carried on are of cotton and leather, but not to any great extent. The trade of the place is chiefly coasting trade: there being little foreign commerce, except the annual importation of a cargo or two of British American timber. The exports are grain, malt, potatoes, bacon, freestone, and Scotch timber: the imports, coal, lime, slate, timber, herrings, salt, colonial produce, and general merchandise from Liverpool and Whitehaven.* There is a freestone quay to enable vessels to take in or discharge their lading. There is a salmon fishery in

* See Appendix to Dr. Singer's *Agricultural Survey of Dumfriesshire* (Edinb. 1812), from which these particulars of the trade of Annan are chiefly taken.

the river, and the sea yields cod, turbot, and a variety of small fish. The rise of the tide on the coast is twenty-one feet.

The parish of Annan extends three miles along the coast, and eight miles inland, and had a population, in 1831, of 5033. It is intersected by the river. It yields a considerable quantity of potatoes, and contains quarries of freestone, limestone, and granite. The living is in the Presbytery of Annan and Synod of Dumfries, and in the patronage of the earl of Hopetoun. There is a flourishing academy lately established and endowed by the heritors and the burgh council.

Annan is thought to have been a Roman station. It was held in fief, with the whole territory of Annandale, by the ancestors of Robert Bruce. This family had here a stately castle, of which the ruins may still be seen. Upon the succession of the Bruces to the throne, Annan became a royal burgh, and it now returns a member in conjunction with Dumfries, Sanquhar, Kirkcudbright, and Lochmaben. (Sinclair's *Statistical Account of Scotland*, &c.)

ANNAN, a river of Scotland, which rises in the mountain range that runs along the northern boundary of Dumfriesshire. It has a general southern course in a long narrow valley, into which a number of small lateral valleys open. The Moffat Water, which is the chief branch of the river, rises in Loch Skene, at an elevation of 1300 feet. The whole course of the Annan is perhaps about forty miles.

ANNANDALE, the district on the banks of the above river, and the middle division of the county of Dumfries. It formed, under the designation of the stewardry of Annandale, one of the three jurisdictions into which the shire of Dumfries was once divided: the others were the shire of Nithsdale and the regality of Eskdale. A stewardry was a district governed by a sheriff or *steward* appointed by the king.

ANNA'POLIS, a town in Maryland, on the south-west bank of the Severn, near its outlet into Chesapeake Bay, 36° 57' N. lat., 76° 27' W. long., and twenty-five miles E.N.E. from Washington. Annapolis, though only an inconsiderable place with a population of about 2260, has been the seat of government for Maryland ever since 1699. The chief building is the state-house. The total tonnage of the district of Annapolis up to December 31, 1831, was only 3472, enrolled and licensed, of which 332 was employed in the coasting trade. (*Report on the Commerce and Navigation of the United States, 2d Congress, 22d Session.*)

ANNA'POLIS, a county of Nova Scotia, in the north-western part of the province, bordering on the Bay of Fundy. It contains six townships, and returns five members to the provincial parliament. The first European settlement in Nova Scotia was made by the French in this quarter, in the year 1604, at the place where the town of Annapolis Royal now stands. The French settlement was called Port Royal, and was twice taken by the English, once in 1614, and again in 1710, by expeditions fitted out from the colonies of New England. On this last occasion, the name of the town was changed to Annapolis, in honour of Queen Anne; at the same time the province, which had been called Acadia by the French, had its name changed to Nova Scotia. Under this name it was ceded to England by France in 1713, and has since continued in British possession.

The town of Annapolis remained the seat of the provincial government until 1750, when, upon the founding of Halifax by Governor Cornwallis, the government offices were transferred to the new town.

The town of Annapolis, situated in 44° 40' N. lat., and 65° 37' W. long., is built on a peninsula formed where the two rivers, Annapolis and Allen, discharge themselves into Annapolis Bay. Since the building of Halifax, it has lost much of its importance. The government buildings and fortifications have fallen to decay, and the trade of the place is much diminished.

The river Annapolis, which rises in the township of Cornwallis, King's County, runs parallel with the Bay of Fundy for about seventy miles, and falls into that bay through Digby's Gut, having previously expanded into a wide estuary, called Annapolis Bay. The river is navigable for boats and small vessels through the greater part of its course. The population of the county, at the census taken in 1827, was 14,661. (Bouchette's *British Dominions in North America*; Monsom's *Letters from Nova Scotia*; McGregor's *British America*.)

ANNA'TES, from 'annus,' a year, a sum paid by the person presented to a church living, being the estimated value of the living for a whole year. It is the same thing

that is otherwise called Primitias, or First Fruits, under the last of which terms the origin and history of the payment will be treated of. We may merely mention here that the amount of the annates in each cure was formerly regulated, in England, by a valuation of benefices, made by Walter, bishop of Norwich, under the direction of Pope Innocent IV. in the year 1254, in the reign of Henry III.—that a new valuation was made in 1292, in the reign of Edward I.—and a third in 1535, in the reign of Henry VIII., according to which last, commonly called the Liber Regis, or King's Book, the clergy are at present rated. These fines went formerly to the bishop or the pope; but on the king being recognized as head of the church at the Reformation, they were transferred to the crown. In the reign of queen Anne, however, they were given up in England to form a fund for the augmentation of poor livings. In Ireland, until the act of last session for the reform of the church, they were applied in the first instance to the repair of churches, and to the augmentation of poor livings after that object had been satisfied. By the late act the demand of first fruits is abolished in that country, and in lieu of it all ecclesiastical incomes above a certain amount are to pay yearly a tax regulated by their value. In Scotland, by an act passed by the parliament of that kingdom in 1672, the heirs or executors of every holder of a spiritual benefice are allowed the first half-year's stipend after that to which the incumbent was entitled at the time of his death; and this is called the Ann, or Annat. As it belongs to the executors of the clergyman, and not to himself, it can neither be assigned by him during his life, nor seized in payment of his debts. [See FIRST FRUITS.]

ANNE OF AUSTRIA, queen of Louis XIII. of France, and regent during the minority of Louis XIV., occupies a prominent place in French history. Daughter of Philip II of Spain, she became the wife of the young Louis XIII. in the year 1615. It is worthy of remark, that the will and policy of the great princes who have governed France have always been untraced by their queens or female favourites, thus exemplifying the witty saying of Louis XIV.'s granddaughter, that when queens reign, men govern, and that when kings reign, women eventually decide the course of events. The great Henry IV. of France had for his darling project the humbling of the House of Austria. His queen, Mary of Medicis, was averse to this policy, and no sooner was Henry in his grave than she took measures for a reconciliation with Spain, and sealed it by a double marriage, one of which was that of young Louis XIII. with Anne of Austria. The administration, however, fell in a few years into the hands of that master-spirit, cardinal Richelieu, who resumed Henry IV.'s views of humbling the pride and ambition of the House of Austria. In this he instantly found an enemy in Anne of Austria, and a struggle ensued betwixt them, in which Anne, though a queen, and a queen regnant, was compelled to yield, as long as he lived, to the great minister.

Had Anne been a woman of greater talents or more pleasing character, it might have been otherwise, but her Spanish education, her coldness and gravity of demeanour, which only covered frivolity of thought, alienated, rather than attracted Louis XIII. Upon this feeling Richelieu worked, and he was able at once to inspire Louis with dislike and with jealousy of his queen. Her natural attachment to her native country was another fault which the cardinal represented as a crime, and his whispers as to her betraying intelligence brought upon Anne the ignominy of having her person searched, and her papers seized by the jealous vigilance of officers commissioned by Louis himself. When it was generally known that the queen was in disgrace, and was the object of Richelieu's anger and mistrust, this was sufficient to rally around her the host of discontented nobles, with Gaston, the king's brother, at their head: they were all jealous of the minister's ascendancy, and fearful of his schemes, which menaced the remaining independence of the aristocracy. It does not appear that Anne was more privy to their plan of resistance and rebellion than she could have avoided being. But her name was unavoidably implicated, and the artful cardinal made of this a specious tale for the king's ear. He represented Anne as disgusted with her royal husband, and endeavouring to get rid of him through conspiracy, in order to place Gaston, duke of Orleans, in his stead. Louis XIII. fully believed this malicious tale, and compelled his queen to appear at the council-table, there to listen to this grave charge from

the royal mouth. In such a situation, Anne's dignity of character came to her aid. She scorned to reply directly to such a charge, but observed contemptuously, 'That too little was to be gained by the change, to render such a design on her part probable.'

What gave most force to Richelieu's tale, was the court which the duke of Buckingham had openly paid to the queen of France. Madame de Motteville, Anne's attendant, who has written the memoir of her life, gives a circumstantial account of the arrogant passion of Buckingham, and confesses that the suit of the English duke pleased the queen's vanity, if it did not touch her heart. On one occasion, after having taken leave on his return to London, he hurried back from Amiens, found his way into the queen's sleeping-room, where it was usual for her to receive visits, flung himself on his knees by the bedside, and gave full vent to a passion that shocked the attendants, as passing beyond the bounds of etiquette. Anne gave but a gentle reprimand. Neglected by her husband (who partook not of her bed for twenty-three years after their marriage), Anne was not insensible to the chivalric attachment of a noble and a statesman, and might perhaps have given some handle to malicious insinuation. At all events, she remained without influence, alienated from the king's affections and council, till death took away monarch and minister, and left to Anne, as mother of the infant monarch, the undisputed reins of power.

There was then a change of policy similar to that which had taken place on the death of Henry IV. Mary of Medicis had counteracted and abandoned all his schemes for humbling Austria, by making peace with that rival power. Anne, of Austrian blood, now did the same, from hatred to Richelieu's memory, as much perhaps as from family affections. She did this with less abruptness, indeed, than Mary, having the good fortune and good sense to have and to choose for her minister a man bred in Richelieu's school, one who had learned his address, but who had never been endowed with his disinterestedness and high views. This was Mazarin. Anne's selection of such a man for minister is the greatest proof of her discernment. As a foreigner, he was completely dependent on the hand that raised him; and consequently there was less danger of his becoming ungrateful, as Richelieu had been to Mary of Medicis. For the same reason, he was unconnected with any powerful party, and the queen made full use of his abilities, without being in danger from his ambition.

Anne of Austria's policy in this choice, though perhaps the wisest, was still not the less fraught with danger. It alienated from her at once the party of the noblesse, which, crushed by Richelieu, had made common cause with Anne in her disgrace, and now raised its head to claim vengeance and spoil. Amongst them were even the queen's peculiar friends, the duke of Beaufort, who was a kind of favourite, and the duchess of Chevreuse, the bosom companion of Anne. Mazarin's advice compelled his mistress to resist the unreasonable demands of these, her former partizans; and the consequence was a general conspiracy against the queen and her minister. Beaufort was sent to prison, and madame de Chevreuse again exiled. Mazarin, like his predecessor, might have triumphed over the noblesse alone; but this class now called to its aid a new, and hitherto neglected body, that of the citizens, or burgess-class. These were easily inflamed against Mazarin as a foreigner, and as a financier, fertile in the invention of new taxes. In addition to this, the great offices of the judicature, which had become venal, had fallen into the hands of the middle or citizen-class, and the magistracy, being possessed of the power of sanctioning or resisting the royal edicts, made common cause with the citizens, and thus a powerful combination was raised against the authority of Anne. An attempt on her part to treat the magistrates as she had treated the duke of Beaufort, by imprisoning them, gave birth to a popular insurrection, which proved successful. The queen and court were for a time prisoners in the Palais Royal, and compelled to submit to the dictates of the mob. The Spanish pride of the queen was with difficulty induced to submit to necessity. She threatened at first to fling the heads of the captive magistrates to the mob, rather than deliver their persons, and her indignation at the time provoked a powerful enemy in the future cardinal de Retz. But she was compelled to smother both pride and anger. The people had their will. The court, however, took the first opportunity of escaping from Paris

and recurring to arms. A civil war commenced between Anne, her minister, and their adherents on one side; and the noblesse, the citizens, and people of Paris on the other.

One might think that the advantage in such a quarrel must necessarily remain to the latter. But Anne and Mazarin's address, after many vicissitudes of fortune, came off triumphant. First they rallied a considerable portion of the army, and the king's name was to them a tower of strength, which enabled them to resist the formidable rebellion of the capital. The *Frondeurs* too, as the insurrectionists were playfully called, were not very earnest in their rebellion. There was no enthusiasm, no fanaticism. The resistance was rather the effect of momentary impatience and despite, which vented itself in epigrams more than in deadly missiles. The young noblesse considered the campaign as a frolic, and however the citizens and magistrates might wish to obtain a certain measure of political freedom, similar to that for which England had so lately struggled, it was evident that the nobles looked with no favour on such schemes, and would eventually concur to mar them. Seeing this, the magistracy determined to bring about an accommodation. It was no easy task. A suspension, or rather a cessation of hostilities, was produced by the retirement of Mazarin.

He returned, however, for Anne was but a cypher without her minister; and the war again broke out. The court had secured a defender in Turenne, who triumphed even over all the valour of the young noblesse, headed by the great Condé. The result of the rebellion, and of Anne of Austria's administration, was, that the nobles and middle classes, vanquished in the field, were never afterwards able to raise their heads, or to offer resistance to the royal power, up to the period of the great revolution. Louis XIV. is, in general, said to have founded absolute monarchy in France. But it was rather the blunders and the frivolity of those who idly espoused the cause of freedom during that monarch's minority which produced this effect. Anne of Austria's triumph was that of monarchy. She, or at least the events of her regency, contributed far more to it, than all the subsequent imperiousness of Louis XIV.; and hence the epoch of Anne's administration is one of the most important in French history.

Anne must have been of pleasing exterior, as not only the account of M. de Motteville, but her portrait in the Vienna gallery, testifies. That she was unchaste does not appear, notwithstanding all the accusations of her story-telling times. Though not a woman of talents, she was at least fortunate in her regency; above all, in her choice of Mazarin. Her influence over the fate and the court of France continued for a long time; her Spanish haughtiness, her love of ceremonial, and of all the pride of power, were impressed by education upon the mind of her son, Louis XIV., who bears the blame and the credit of much that was hers. Anne of Austria died at the age of sixty-four, in the year 1666.

ANNE, queen of England, the second daughter of James II. by his first wife Anne Hyde, was born at Twickenham on the 6th February, 1664. She was educated in the religion of the Church of England; and, in 1683, was married by the bishop of London to prince George, brother of Christian V., king of Denmark. At the revolution in 1688, Anne and her husband adhered to the dominant party of her brother-in-law William III.; and, by the act of settlement, the English crown, in default of issue to William and Mary, was guaranteed to her and her children. During the

reign of William she appears to have lived in much discomfort, neglected by her sister, and treated with coldness by the king; and she sustained the heavier affliction of losing all her children in infancy, except one son, the duke of Gloucester, who died at twelve years of age, in 1699. This event, as well as the previous death of queen Mary, rendered an alteration in the act of settlement necessary; and the princess Sophia, dowager electress of Hanover, and her descendants being Protestants, were declared next heirs to the throne, in default of direct heirs to William and his sister-in-law Anne. [See SETTLEMENT, ACT OF.] The exiled king James II. died on the 16th November, 1701; and Louis XIV. of France having recognised the claims of James's son to the English throne, William III. commanded the return of his ambassador from France, and dismissed the French ambassador from England. Another cause of hostility between France and England had arisen in the recognition by Louis XIV. of the claim of his grandson, Philip of Anjou, to the crown of Spain. The PARTITION TREATIES between France, England, and Holland, in 1698 and 1700, had otherwise regulated the succession of Spain. The first treaty declaring Joseph Ferdinand, electoral prince of Bavaria, presumptive heir; and the second, upon the death of Joseph Ferdinand, declaring the archduke Charles presumptive heir. The will of Charles II. of Spain, who died November 1, 1700, by giving the crown to Philip of Anjou, had materially disturbed the balance of power in Europe established by the PEACE OF RYSWICK in 1697; and the recognition by France of this testamentary disposition, in violation of the partition treaties, united, in 1701, England, Holland, and other European powers, in the determination to resist an arrangement which seemed to bestow such a formidable preponderance upon the French monarchy. [See HAGUE, ALLIANCE OF.]

Under these circumstances, Anne ascended the throne, upon the death of William III., on the 8th March, 1702. The hostility between the whig and tory faction at home, which went on increasing in violence to the end of the reign of Anne, was in its commencement greatly mitigated by the united opinion of the country as to the justice and policy of the war with France and Spain. On the 4th May, within two months after Anne had succeeded to the throne, war was declared by England, the Empire, and Holland, against these powers. The general progress of this memorable war will be detailed under the head SUCCESSION, WAR OF. The extraordinary campaigns in the Low Countries and Bavaria, by which the military glory of England was raised higher than at any period since the days of Edward III., will be described in the life of MARLBOROUGH; the brilliant successes of the English arms in Spain under lord PETERBOROUGH will be found in the notice of that singular commander; and the naval exploits of this war, of which the most signal examples were the capture of GIBRALTAR and PORT MAHON, will be found in our accounts of those places; and in the biographies of the English admirals, LEAKE, ROOKE, SHOVEL, and STANHOPE.

The legislative union of Scotland and England, completed on the 27th July, 1706, was one of the most important events in the reign of Anne, of which the progress and consequences will be detailed in their proper place, SCOTLAND, UNION OF.

During the brilliant course of Marlborough's conquests, the spirit of political intrigue, which was perhaps never more fully developed than in the latter years of the reign of Anne, was stifled by the enthusiasm of the people. But as the war of the succession proceeded with few indications of its being brought to an end, the great commander of the English forces gradually lost his popularity, from the belief that his own avarice and ambition were the principal causes of the burdens which the war necessarily entailed upon the nation. A formidable party, too, had arisen, who asserted the supremacy of the church and the doctrine of the right divine of kings and the passive obedience of subjects—opinions which had expelled James II. from his kingdom, and had placed his childless daughter upon the throne. These opinions, however, were supposed to be indirectly encouraged by the queen, and were exceedingly popular amongst a passionate and unreasoning people. The impeachment of Dr. SACHSVEREL for preaching these opinions,—his mild punishment, which had the effect of a real acquittal,—and his subsequent triumphant progress through the kingdom, furnished an unerring presage of violent changes. In the elections of 1710 the tory supremacy was established. The

duchess of MARLBOROUGH, to whose talents and decision of character the queen had long submitted, was thrust out by the new favourite, Mrs. MASHAM. The ministry of GODOLPHIN and SUNDERLAND was displaced by that of BOLINGBROKE and OXFORD. The command of the army was taken from Marlborough and bestowed upon the duke of ORMOND. During the progress of these convulsive changes, which must have been distracting enough to the quiet temper of Anne, she was deprived of the sympathy of her placable husband. Prince GEORGE OF DENMARK died on the 28th October, 1708.

The first act of the tory ministry was to enter upon arrangements to bring the war to a conclusion. In 1711 negotiations were entered into with France, amidst the protestations of the allies of Great Britain, and these negotiations, after various difficulties, were terminated by the memorable treaty of April 11, 1713. [See UTRECHT, PEACE OF.]

By the treaty of Utrecht the succession to the crown of Great Britain had been guaranteed to the House of Hanover. But a suspicion began soon to prevail that the queen and a portion of her government secretly favoured the pretensions of the son of James II. The minority in parliament attempted to carry several measures which would bring these supposed partialities to a test. The queen was compelled to invite the Electress of Hanover to England; and upon the death of that princess in June, 1714, to issue a proclamation offering a reward for the apprehension of her brother should he attempt to land in Great Britain or Ireland. It is affirmed by a writer in the *Biographie Universelle*, upon the authority of some secret memoirs, that the son of James II. at this juncture clandestinely visited England, and in an interview with his sister concerted measures for defeating the Hanoverian succession. The tory ministry was, however, shattered by the quarrels of Oxford and Bolingbroke; the whigs carried the nation along with them in their denunciation of the peace of Utrecht, which had left the country little besides a barren glory; and the dissatisfaction with the union of Scotland threatened to break out in open insurrection. The health of the queen gave way under these distractions. On the 20th July, 1714, she prorogued parliament for a month, and falling almost immediately after into a state of weakness and lethargy, died on the succeeding 12th of August. It is said that her last words were an expression of pity for her brother.

The reign of Anne has been called the Augustan age of English literature. It produced Addison, Arbuthnot, Congreve, Pope, Prior, Steele, and Swift, writers of a high degree of excellence in their particular walks, but scarcely to be compared with the great poets of the reign of Elizabeth, or with a few other illustrious names of a succeeding generation, such as Milton and Dryden.

ANNEALING. There are certain substances, more especially glass and some of the metals, which on sudden cooling after having been melted, acquire great brittleness, and in the case of glass, a disposition to fly to pieces by moderate changes of temperature, or slight external force. This is remedied by annealing, which, with respect to glass, consists in heating it, below the point at which it softens, in what are termed *annealing ovens*, the glass being gradually removed from the hotter to the cooler parts of the furnace. The brittleness of glass has been attributed to the disturbance, attendant upon the hasty cooling, in the regular arrangement of its particles. [See GLASS.]

The metals also suffer remarkable changes as to their hardness, toughness and brittleness; this is especially the case with iron after it has been converted into steel. The alteration of structure which they undergo is not thoroughly understood; it is, however, certain that some malleable metals which crystallize on cooling, are brittle in their crystalline state, and that this structure is altered, and they are rendered tough by heating and rolling. This is remarkably the case with zinc, which is incapable of extension under the hammer, except in a slight degree, without cracking; but when it has been passed through the rollers, at a moderate increase of temperature, it becomes almost as flexible and as tough as copper. This change must be derived from some alteration of structure, and fresh arrangement of the particles, which must be considered as owing to a process, if not identical with annealing, yet bearing a strong analogy to it. [See BRASS AND STEEL.]

ANNECY, an episcopal city of Savoy, on the north bank of the Lake of Annecy, stands at the extremity of a beautiful

plain surrounded by delightful eminences and lofty calcareous mountains, and at an elevation of 1456 E. feet (Sausure) above the level of the sea. It is 22 miles N.N.E. of Chambéry. Annecy is the principal seat of manufacturing industry in Savoy, and has between 5000 and 6000 inhabitants, with establishments for cotton-spinning, calico-printing, and a glass-house. Some iron-mines are worked in the neighbourhood.

The Lake of Annecy washes the edge of the town. Its greatest length is about nine miles and a quarter, and its average width three. The greatest depth is 196 E. feet. This lake discharges itself by several canals, said to be Roman work, all of which unite just beyond the town of Annecy in one stream, called the Thion, which empties itself into the Fier, a tributary to the Rhone.

ANNE'LIDA (Cuvier), an extensive division or class of animals, established by modern naturalists partly at the expense of Linnæus's heterogeneous class of worms (*vermes*). It was Baron Cuvier who first proposed to distinguish the annelida in 1802, chiefly on account of their blood being of a red colour, as in the leech, and circulating by means of a double system of complicated blood-vessels.

The name is derived from the Latin word *annulus*, a ring, because the animals arranged under this division always have their bodies formed of a great number of smaller rings, as in the earth-worm. Their external covering, or skin, is soft and pliable, and their bodies, having no bony skeleton, are soft, and in general more or less of a cylindrical form.

The annelida are for the most part oviparous, but the leeches and earth-worms deposit what are termed capsules, or membranous cocoons, containing many embryo young.

There is little variety in their mode of life. Some live in fresh and others in salt water; and others, like the hair-worm (*Gordius*), are amphibious. Some species construct tubes in the interior of stones, or in shells, which they perforate, or in madrepores. Some species again form calcareous cases, or cement around them various foreign substances, particularly sand. The sedentary species are timid, and when taken from their retreats can neither escape nor defend themselves. The *Errantia*, on the other hand, are frequently very nimble, and can defend themselves well by means of their bristles.

The researches of Baron Cuvier and M. Savigny did much to produce a clear arrangement of the animals under notice according to their physiological structure; and hence MM. Audouin and Milne Edwards, who have more recently investigated the structure of many species, have in part adopted the classification, slightly modified, of those naturalists. They make four divisions, groups, or orders, each differing in structure and in manners—the *Errantia*, the *Tubicola*, the *Terricola*, and the *Suctorio*.

The *Errantia* (*Nereidæ*, Savigny, *Dorsibranchia*, Cuvier) are, with few exceptions, essentially fitted for walking or swimming, and are rarely sedentary. They have in general a head distinct from the body, with antennæ and eyes. Their mouth is furnished with a protractile tube, more or less distinct, and in general with jaws.

The *Tubicola* (Cuvier) are essentially sedentary, and live almost uniformly in the interior of solid tubes, which their structure forbids them to quit. Their respiratory organs are usually observable on a certain number of the segments of their bodies, commonly at the anterior extremity. The feet are distinct, though short, and always armed with hooks as well as bristles. The head is not distinct, and they have no eyes, antennæ, nor jaws.

The *Terricola* always live in a hole or gallery in the ground, and are without feet, instead of which they have some short bristles to aid their movements. They have no distinct head, eyes, antennæ, or jaws. The mouth is always terminal, and sometimes furnished with tentacles.

The *Suctorio* differ from all the preceding in having neither feet nor bristles, and by being furnished at each extremity of the body with a prehensile cavity or sucker. They have no distinct head, but may almost always be observed to have eyes and jaws. They are chiefly parasites, and live at the expense of other animals.

ANNIBAL. [See HANNIBAL.]

ANNIUS of Viterbo, a well-known Dominican monk, who lived in the fifteenth century. His real name was Giovanni Nanni, but in conformity with the custom of the age he Latinized it, and dropped the first letter, in order to render it more completely classical. He was born at Viterbo, in 1432, and died in 1502. He entered early into the

Dominican order, and became famous for his acquaintance with the Eastern as well as the Greek and Latin languages. His works are voluminous: the most remarkable is entitled *Antiquitatum Rariorum Volumina XVII., cum Commentariis Fr. Joannis Annii Viterbiensis*, in folio, Rome, 1498, several times reprinted. This collection professes to contain a number of historians of high antiquity, Berossus, Manetho, Myrsilus the Lesbian, Fabius Pictor, Marcus Cato, and others, whose works, hitherto unknown, he professed to have discovered at Mantua. That these pretended historians were forgeries, there can now be no doubt; whether Annii was deceived or the deceiver, whether he forged them himself, or suffered from credulity and want of penetration, is a matter on which authorities are divided, and which it is of little moment to discuss now. He published two other works which excited a great sensation from the circumstances of the times, and the recent capture of Constantinople, one entitled *Tractatus de Imperio Turcorum*, the other, *De Futuris Christianorum Triumphis in Turcos et Saracenos ad Xystum IV., et Omnes Principes Christianos*, being the substance of a set of sermons preached by him at Genoa on the Apocalypse. (*Biog. Universelle*; see also Bayle and Moreri.)

ANNIVE'RSARY, the yearly return of any remarkable day, called, in old English, by the expressive term year-day.

Anniversary days are festivals celebrated by the Romish church in honour of the saints, one or two of whom are assigned to every day in the year. The long catalogue of saints being unknown to the church of England, anniversary days are not generally made a matter of religious observance. Some few days, unconnected with religion, are however still noticed. The birth-day of the reigning monarch is very generally celebrated by holidays and rejoicings; the anniversary of the Gunpowder Plot has been rescued from oblivion by the love of school-boys for fire-works and the pageant of Guy Fawkes; and the oaken bough still preserves the remembrance of the restoration of the Stuarts.

Literary and scientific associations generally celebrate the anniversary of their original institution, and social parties are still held in domestic life on the birth-days of heads of families; with these exceptions, the observance of particular days has greatly declined in England.

ANNO. [See HANNO.]

ANNO BOM, the smallest and most southern of the four islands in the bight of Biafra, is about four miles long and two broad. It is mountainous, and rises abruptly from an unfathomable depth to the elevation of near 3000 feet; but with the exception of one precipitous mass, the heights are of a rounded form. The ascent to this peaked summit is very steep and dangerous, owing to the looseness of the numerous stones which cover the side of the slope, and are in a state of decomposition. At the foot of this height is a small shallow lake, about three-quarters of a mile round, with a bottom of stiff bluish clay: the water was found to be very sweet.

The regular winds are from the S.W.: less rain falls here than in the other islands of the bight; the rainy season is confined to April and May, and October and November. The precise character of the climate as to health seems still doubtful. This island is chiefly visited for supplies of sheep, goats, pigs, fish, cocoa-nuts, bananas, lemons, Seville oranges, &c. Fowls are scarce. There is plenty of water on the island, but the heavy surf on the shore makes it difficult to procure. The population is about 3000, who live chiefly in a large village near the north-east point of the island, off which is the only tolerably safe roadstead for shipping round it. The natives are quite harmless. Their houses, which are small, are rudely constructed of rough boards, grass, mud, and the foot-stalks of the cocoa-nut tree. This island was discovered by the Portuguese in 1473, but is now governed by a native of the island, who is totally independent of the Portuguese, but appears to have no great authority.

Anno Bom lies in 1° 24' S. lat., and about 6° E. long.; but we are not able to state its longitude accurately. Cape Lopez is the nearest part of Africa to Anno Bom. (From *Memoir descriptive of Prince's Island and Anno Bom*, by the late Captain Boteler, R.N. *London Geog. Journal*, vol. ii.)

ANNONAY, a town in France near the northern extremity of the department of Ardèche, at the junction of two rivers, the Diaume (or Déom) and the Canche, whose united streams flow into the Rhone, from the right bank of which Annonay is only five or six miles distant. The town

itself, which is neither large nor handsome, stands on the tongue of land between the two streams above-mentioned, by which it is separated from its suburbs. It is celebrated for its paper, which is considered the best in France; and it also has manufactories of cloths, silks, cotton, wax, and leather. It is the busiest town in the department, and its population has risen with great rapidity until it has surpassed that of any other place in Ardèche. In the *Encyclopédie Méthodique*, (published in 1782,) it is called "petite ville," (a small town,) in the *Dictionnaire Universelle de la France*, (1804,) the inhabitants are given at 3800; but the latest authorities (MM. Brun and Balbi) raise it to 8000. It is about thirty-four miles in a straight line north of Privas, capital of the department.

Annonay was the birth-place of Mongolfier the aéronaut, and of the Count Boissy d'Anglais; to both of whom monuments have been erected by their townsmen.

ANNUAL REGISTER. The earliest English publication which has any claim to be considered as an *Annual Register* is Edward Chamberlayne's *Angliæ Notitia, or the Present State of England*, which first appeared in 1668, and continued to be annually republished with the requisite alterations till the year 1703 inclusive. But this work, as its title indicates, presented merely an account of the country in its existing state, with lists of public functionaries, &c., and gave no register of occurrences. Our first history of the year, we believe, was that given in the *Political State of Europe*, which was begun in 1711 by Abel Boyer, a French refugee, and the author of the well-known *French and English Dictionary*. This publication was continued till the year 1739. Although this work appeared also in annual volumes, it was really published in monthly numbers. In 1716 was commenced the *Historical Register*, a quarterly publication, which in like manner was republished in volumes at the end of each year. The regular publication having taken up the history of public affairs only from the 9th of January, 1716, two volumes were printed together in 1724, containing an account of events from the last day of July, 1714, up to that date, being the first seventeen months of the reign of George I. With these introductory volumes, therefore, the *Historical Register* forms a chronicle of the affairs of this and other countries of Europe from the accession of the House of Hanover. The compilers, to use their own words, confine themselves to mere 'matters of fact, without making any descent thereon either of commendation or reprehension.' This work also, about the year 1737, began to appear in monthly numbers. The change was probably a dying effort, as the volume for 1738 was, we believe, the last that appeared. The *Historical Register* was printed and sold by G. Meere in the Old Bailey. The price, while it was published quarterly, was one shilling each part.

The first *Annual Register*, properly so called, which appeared in this country, was the well-known and valuable work which still continues to be published under that title. This work was projected by Robert Dodsley, the bookseller, in conjunction with Edmund Burke, who was already well-known in the literary circles of the metropolis as the author of the *Essay on the Sublime and Beautiful*, the *Vindication of Natural Society*, and other anonymous works. The first volume of Dodsley's *Annual Register* appeared in June, 1759, under the title of *The Annual Register, or A View of the History, Politics, and Literature of the Year 1758*, printed for R. and J. Dodsley, in Pall-Mall. In the Preface are enumerated the several points of novelty in respect of which the work is conceived to have an advantage over its predecessors; and of these the first-mentioned is that it is an annual, and not a monthly publication. Others are, that it takes up the history of the war in which the country was then engaged, from its commencement in 1755; that it contains a collection of state-papers, illustrative of the historical narrative; and that, by its miscellaneous department and its notices of new books, it unites the plans of the magazines and reviews. The history in this volume consists of seventy-six pages divided into thirteen chapters, the first seven of which, running to thirty-two pages, are occupied with the first three years of the war. Then follow in order the chronicle, extending to sixty-seven pages; the collection of state-papers; characters; extraordinary adventures, including an account of the sufferings of the persons confined in the Black Hole at Calcutta in June, 1756; literary and miscellaneous essays; poetry, including pieces by Akenside, William Whitehead, and the king of Prussia; and lastly,

an account of remarkable books published in 1758, among which are Jortin's *Erasmus* and Walpole's *Royal and Noble Authors*. The volume consists of 496 pages in all, besides Preface, Contents, &c. This and several of the succeeding volumes were so popular that they quickly ran through five or six editions. There is no doubt that, for some years, the historical narrative was written by Burke, who also probably edited the publication and selected the rest of its contents. He appears to have been paid for his services at the rate of 100*l.* the volume. Mr. Prior, in his *Life of Burke*, has given engraved fac-similes of two receipts signed by him for two sums of 50*l.* paid to him by Dodsley for the *Annual Register* of 1761, the first dated on the 28th of March in that year, and the second on the 30th of March in the year following. This volume was not published, as appears by the preface, till a later period than usual in 1762. These receipts are in the possession of Mr. Upcott of the London Institution. Burke took a great interest in the conduct of the *Annual Register* almost as long as he lived; and Mr. Prior states that much of it was written from his dictation for about thirty years. Latterly it was written by a Mr. Ireland under his direction. It is generally believed that the work again received occasional contributions from Burke after the breaking out of the French revolution; and certainly some of the volumes belonging to that period are written with remarkable ability. To the departments above enumerated were afterwards added others of natural history, useful projects, and antiquities; together with lists of promotions, marriages, births, deaths, and patents; but some of these heads have been since discontinued. The difficulty of bringing out the work within six months of the close of the year appears to have been very early felt. In volume third the *Chronicle* has, for the first time, a different paging from the *History*, according to the plan which is still followed, having, as is stated in the preface, been put to press before the *History* was ready, in order to expedite the publication. The work, however, gradually fell into arrear, and at length, instead of some months, it was nearly as many years after the events had taken place till their history appeared. The publication was in this state about the year 1780. Great exertions, however, were soon after made by the conductors to recover their lost ground; on one occasion, two years, 1784 and 1785, were compressed into one volume. the 27th; and early in 1801 they had the satisfaction of publishing the volume for the year immediately preceding: thus closing the century with the work completed up to that date. Since then the publication has proceeded regularly at the rate of a volume each year. That last published, being the *Annual Register* for 1832, is the 74th of the series. Of the older volumes, several have been reprinted of late years in order to complete sets. An index to the work, from its commencement to the year 1780 inclusive, was published soon after the completion of the volume for that year, and has been several times reprinted; and in 1820 a second index appeared, comprehending the former, and embracing also all the additional volumes up to that for 1819 inclusive.

In 1781 was published the first volume of the *New Annual Register*, containing the history of the preceding year. It was projected and originally edited by Dr. Kippis; after whose death, in 1795, it was conducted by the Reverend Thomas Morgan, LL.D., the coadjutor of Dr. Aikin in the preparation of his *Biographical Dictionary*. Watt, in his *Bibliotheca Britannica*, states that this publication was at one time edited by the late Mr. John Mason Good; but we do not observe that this is mentioned in Dr. Olinthus Gregory's life of that gentleman. The *New Annual Register* was continued till 1825, but it never attained the reputation of its predecessor and rival.

The *Edinburgh Annual Register* was commenced in 1808, and was continued at least till 1825. We believe it is no longer published. Some of the earlier volumes of this work were written by Sir Walter Scott and Mr. Southey; and it was throughout conducted with great ability.

Other works of this description are the *Annual Anti-Register*, begun in 1799; the *Baptist Annual Register*, first edited by the late Dr. John Rippon; the *Historical, Political, and Literary Register* for 1769, published in 1770; and the *Imperial and County Annual Register* for 1810, in 2 vols. 8vo. 1811. The two last mentioned seem to have been dropped after the first year.

A French work, in imitation of the English *Annual Registers*, was commenced at Paris in 1818, under the title of

Annuaire Historique Annuel; and there is also the *American Annual Register*, published at New York.

ANNUALS. By this name gardeners designate all plants which, if sown in the spring, will flower, perfect their seed, and perish in the course of the same season; if two seasons are generally requisite for this purpose, they then call plants biennials—but in fact they are both of the same nature: annuals, if sown in the autumn, become biennials; and the latter, if sown early in the spring, will go through every stage of life in the same year; the only difference between them is, that biennials are rather longer in completing the term of their existence than annuals are.

Physiologically considered, such plants belong to a much more extensive body of vegetables than is usually supposed. Plants may be said to consist of two kinds, those which perish after once producing their fruit, and those which continue to grow and produce fruit year after year. To the first of these classes belong not only annual and biennial herbs, but also many palms, the agave, and several other monocotyledonous trees.

The usual method of multiplying annuals is by their seed. It is, however, possible to dispense with this mode, and to perpetuate them by cuttings, care only being taken that the part used for a cutting is not in a flowering state; in this way the fugitive beauties of such plants as balsams and the like may be perpetuated. Even cucumber and melon plants may be renovated when in the last stage of decay by their young branches being cut off and made to put forth roots; and the different races of cabbages, the qualities of which can scarcely be preserved by the precarious plan of seed-saving, may be carried forward from year to year. (See *Gardener's Magazine*, vol. ix. p. 226.)

Gardeners distinguish annuals into two kinds, hardy and tender: the first comprehends all those which will grow if their seeds are sown at once in the open border; the last consist of such as require to be raised in artificial heat. The management of both these is so simple and well known that little requires to be said upon the subject: there are, however, two or three points that deserve to be particularly adverted to. The seeds of hardy annuals are apt to be destroyed by birds, or to be scorched up by a continuance of dry weather; both these accidents may be prevented by inverting over the patch in which they are sown a common flower-pot; this should be examined daily, and as soon as the plants are found to be making their appearance, it should be elevated a little by resting its rim on two or three pebbles, so as to admit air and light. After a little while the plants will be fully established, and the pots may be removed.

Two things only are to be observed in the management of tender annuals beyond the ordinary practice of every gardener. Firstly, they should not be raised in a very high temperature if they are afterwards to be planted in the open air; and secondly, the seedlings should never be transferred from the seed-pan at once to the open ground, but should always undergo the intermediate operation of being transferred into small pots. Very great care should be taken not to give them much heat, especially at night, and they should be exposed as much as possible to air after they have once rooted in their pots: unless this is attended to, they become weak and what is called drawn up—or what might be called starved—for this well-known appearance arises from the plants not having been able to consume the necessary quantity of carbonic acid gas, which is, as is well known, the matter on which they feed. Plants can only feed in free air and bright sunlight: if therefore they are prevented from doing this they are starved; for it must not be supposed, that a copious supply of stimulating manure will supply the place of light and air; on the contrary, it will but augment the mischief that results from their deficiency.

ANNUITY (in Law) consists in the payment of a certain sum of money, yearly calculated, and charged upon the person or personal estate of the individual from whom it is due; for if it is charged upon his real estate, it is not an annuity but a rent. [See RENT.] A sum of money payable occasionally does not constitute an annuity; the time of payment must recur regularly at certain stated periods, but it is not necessary that these periods should be at the interval of a year; an annuity may be made payable quarterly, or half-yearly, (as is very generally the case,) or at any other aliquot portion of a year; and it may even be made payable once in two, three, twenty, or any other number of years.

Under the Roman law, annuities were chiefly such as were created by will, constituting a charge upon the heir in

favour of the legatee. (See *Digest*, lib. xxxiii. tit. 1. Domat's *Civil Law*, 2d Part, book iv., tit. 2, sec. 1.) In the middle ages they were frequently given to professional men as a species of retainer; and in more modern times they have been very much resorted to as a means of borrowing money. When the person who borrows undertakes, instead of interest, to pay an annuity, he is styled the *grantor*; the person who lends, being by the agreement entitled to receive the payments, is called the *grantee* of the annuity. This practice seems to have been introduced on the Continent with the revival of commerce, at a time when the advantages of borrowing were already felt, but the taking of interest was still strictly forbidden. In the fifteenth century contracts of this kind were decided by the popes to be lawful, and were recognized as such in France, even though every species of interest upon money borrowed was deemed usurious. (Domat's *Civil Law*, 1st Part, book i., tit. 6.) The commercial states of Italy early availed themselves of this mode of raising money, and their example has since been followed in the national debts of other countries. [See NATIONAL DEBT. FUNDS. STOCKS.]

An annuity may be created either for a term of years, for the life or lives of any persons named, or in perpetuity; and in the latter case, though, as in all others, the annuity as to its security is personal only, yet it may be so granted as to descend in the same manner as real property; and hence an annuity is reckoned among the species of incorporeal hereditaments.

A perpetual annuity, granted in consideration of a sum of money advanced, differs from interest in this, that the grantee has no right to demand back his principal, but must be content to receive the annuity which he has purchased, as long as it shall please the other party to continue it:—but the annuity is in its nature redeemable at the option of the grantor,—who is thus at liberty to discharge himself from any further payments by returning the money which he has borrowed. It may, however, be agreed between the parties (as it generally has been in the creation of our own national debt, which consists chiefly of annuities of this sort) that the redemption shall not take place for a certain number of years. The number of years within which, according to the present law of France, an annuity of this sort (*une rente constituée en perpétuel*) may be made irredeemable, is limited to ten. (See *Code Civil*, Art. 109, &c.)

An annuity for life, or years, is not redeemable in the same manner; but it may be agreed by the parties to the contract that it shall be redeemable on certain terms;—or, it may afterwards be redeemed by consent of both parties: and where the justice of the case requires it, (where there has been fraud, for instance, or the bargain is unreasonable,) a court of equity will decree a redemption. When such an annuity is granted in consideration of money advanced, the annual payments may be considered as composed of two portions, one being in the nature of interest, the other a return of a portion of the principal, so calculated, that, when the annuity shall have determined, the whole of the principal will be repaid. Annuities for life or years, being the only security that can be given by persons who have themselves but a limited interest in their property, are frequently made in consideration of a loan. Besides this advantage, annuities for life, inasmuch as they are attended with risk, are not within the reach of the usury laws, and are therefore often used in order to evade them: the legislature has for this reason thought fit to require that certain formalities should be observed in creating them. It is enacted (by stat. 53 Geo. III., c. 141) 'That every instrument by which an annuity for life is granted shall be null and void, unless, within thirty days after the execution thereof, there shall be enrolled, in the High Court of Chancery, a memorial containing the date, the names of the parties and witnesses, and the conditions of the contract; and if the lender does not really and truly advance the whole of the consideration money,—that is, if part of it is returned, or is paid in notes which are afterwards fraudulently cancelled, or is retained on pretence of answering future payments, or if, being expressed to be paid in money, it is in fact paid in goods,—the person charged with the annuity (that is, the borrower) may, if any action should be brought against him for the payment of it, by applying to the court, have the instrument cancelled.' The same statute also enacts, that every contract for the purchase of an annuity, made with a minor, shall be void, and shall remain so, even though the minor, on coming of age, should attempt to confirm it. The pro-

visions of this act are intended to be confined to cases where the annuity is granted in consideration of a loan.

Annuities may be, and very frequently are, created by will, and such a bequest is considered in law as a general legacy, and, in case of a deficiency in the estate of the testator, it will abate proportionably with the other legacies. The payment of an annuity may be charged either upon some particular fund (in which case if the fund fails the annuity ceases) or upon the whole personal estate of the grantor; which is usually effected by a deed of covenant, a bond, or a warrant of attorney. If the person charged with the payment of an annuity becomes bankrupt, the annuity may be proved as a debt before the Commissioners, and its value ascertained, according to the provisions of the bankrupt act (6 Geo. IV., c. 16, s. 54). The value thus ascertained becomes a debt charged upon the estate of the bankrupt; and hereby both the bankrupt and his surety are discharged from all subsequent payments.

If the person on whose life an annuity is granted dies between two days of payment, the grantee has no claim whatever in respect of the time elapsed since the last day of payment [see *APPORTIONMENT*]: from this rule, however, are excepted such annuities as are granted for the maintenance of the grantee,—and the parties may in all cases, if they choose it, by an express agreement, provide that the grantee shall have a rateable portion of the annuity for the time between the last payment and the death of the person on whose life it is granted. On government annuities a quarter's annuity is paid to the executors of an annuitant, if they come in and prove the death. (See Comyn's *Digest*, tit. *Annuity*; Lumley *On Annuities*.)

ANNUITY, a term derived from the Latin *annus*, a year; signifying, in its most general sense, any fixed sum of money which is payable either yearly, or in given portions at stated periods of the year. Thus, the lease of a house, which lets for 50*l.* a year, and which has 17 years to run, is to the owner an annuity of 50*l.* for 17 years. In an ordinary use of the term, it signifies a sum of money payable to an individual yearly, during life. In the former case, it is called, in technical language, an *annuity certain*, and in the latter, a *life annuity*.

It is evident that every beneficial interest which is either to continue for ever, or to stop at the end of a given time, such as a freehold, a lease, a debt to be paid in yearly instalments, &c., is contained under the general head of an *annuity certain*, while every such interest which terminates with the lives of any one or more individuals, all that in law is called a *life-estate*, and all salaries, as well as what are most commonly known by the name of life annuities, fall under the latter term. Closely connected with this part of the subject are *COPYHOLDS*, (which see,) in which an estate is held during certain lives, but in which there is a power of renewing any life when it drops, that is, substituting another life in place of the former, on payment of a fine—*REVERSIONS*, or the interest which the next proprietor has in any estate, &c., after the death of the present—and *life-insurance*, (see *INSURANCE*), in which the question is, what annuity must A. pay to B. during his life, in order that B. may pay a given sum to A.'s executors at his death.

If money could not be improved at interest, the value of an annuity certain would simply be the yearly sum multiplied by the number of years it is to continue to be paid. Thus a lease for 3 years of a house which is worth 100*l.* a year, might either be bought by paying the rent yearly, or by paying 300*l.* at once. A life annuity, in such a case, will be worth an annuity certain, continued for the average number of years lived by individuals of the same age as the one to whom the annuity is granted. But if compound interest be supposed, which is always the case in real transactions of this kind, the landlord, in the case of the annuity certain just alluded to, must only receive such a sum, as when put out to interest, with 100*l.* subtracted every year for rent, will just be exhausted at the end of 3 years. To exemplify this, let us suppose that money can be improved at 4 per cent. In Table I., in the column headed 4 p. c. (4 per cent.) we find 2.775 opposite to 3 in the first column, by which is meant that the present value of an annuity of one pound to last 3 years is 2.775*l.*, or 2*l.* 15*s.* 9*d.* The present value of an annuity of 100*l.* under the same circumstances is, therefore, 277.5*l.*, or 277*l.* 10*s.* This is the value of a lease for three years corresponding to a yearly rent of 100*l.* The landlord who receives this, and puts it out at 4 per cent., will, at the end of one year, have 288*l.* 12*s.* From

this he subtracts 100*l.* for the rent which has become due, and puts out the remainder 188*l.* 12*s.* again at 4 per cent. At the end of a year this has increased to 196*l.* 2*s.* 10*d.*, from which 100*l.* is again subtracted for rent. The remainder, 96*l.* 2*s.* 10*d.*, again put out at interest, becomes at the end of the year 99*l.* 19*s.* 9*d.*, within three pence of the last year's rent. This little difference arises from the imperfection of the Table, which extends to three decimal places only.

TABLE I.—*Present Value of an Annuity of One Pound.*

No. of Years.	3 p.c.	3½ p.c.	4 p.c.	5 p.c.
1	.971	.966	.962	.952
2	1.913	1.900	1.886	1.859
3	2.829	2.802	2.775	2.723
4	3.717	3.673	3.630	3.546
5	4.580	4.515	4.452	4.329
6	5.417	5.329	5.242	5.076
7	6.230	6.115	6.002	5.786
8	7.020	6.874	6.733	6.463
9	7.786	7.608	7.435	7.108
10	8.530	8.317	8.111	7.722
15	11.938	11.517	11.118	10.380
20	14.877	14.212	13.590	12.462
25	17.413	16.482	15.622	14.094
30	19.600	18.392	17.292	15.372
40	23.115	21.355	19.793	17.159
50	25.730	23.456	21.482	18.256
60	27.676	24.945	22.623	18.929
70	29.123	26.000	23.395	19.343
For ever	33.333	28.571	25.000	20.000

To find the present value of an annuity of 1*l.* per annum continued for 10 years, interest being at 5 per cent., look in the column headed 5 p. c., and there, opposite to 10 in the first column, will be found the value 7.722*l.* or 7*l.* 14*s.* 6*d.* This would be commonly said to be 7.722 *year's purchase* of the annuity. For a convenient rule for reducing decimals of a pound to shillings and pence, and the converse, see the *Penny Magazine*, No. 52. It may also be done by the following table:

TABLES II. and III.—*For reducing Decimals of a Pound to Shillings and Pence, and the converse.*

Dec.	s.	Dec.	s.	d.	Dec.	d.
.1	2	.01	0	2½	.001	0¼
.2	4	.02	0	5	.002	0½
.3	6	.03	0	7½	.003	0¾
.4	8	.04	0	9½	.004	1
.5	10	.05	1	0	.005	1¼
.6	12	.06	1	2½	.006	1½
.7	14	.07	1	5	.007	1¾
.8	16	.08	1	7½	.008	2
.9	18	.09	1	9½	.009	2¼

s.	Dec.	d.	Dec.	f.	Dec.
1	.05	1	.004	¼	.001
2	.1	2	.008	½	.002
3	.15	3	.013	¾	.003
4	.2	4	.017		
5	.25	5	.021		
6	.3	6	.025		
7	.35	7	.029		
8	.4	8	.033		
9	.45	9	.037		
10	.5	10	.042		
		11	.046		

For example, what is .665*l.* in shillings and pence?

TABLE II.	s.	d.
.6	12	0
.06	1	2½
.005		1½
.665	13	3½

Again, what is 17*s.* 10½*d.* in decimals of a pound?

TABLE III.	£	s.	d.	is
10	0	10	0	.5
7	0	0	0	.35
10	0	0	0	.042
½	0	0	0	.003
£0 17 10½				.895

These conversions are not made with perfect exactness, as only three decimal places are taken. The error will never be more than one farthing.

To use Table I. where the number of years is not in the table, but is intermediate between two of those in the table, such a mean must be taken between the annuities belonging to the nearest years above and below the given year, as the given year is between those two years. This will give the result with sufficient nearness. We must observe, that no tables which we have room to give are sufficient for more than a first guess, so to speak, at the value required, such as may enable any one, who is master of common arithmetic, not to form a decisive opinion on the case before him, but to judge whether it is worth his while to make a more exact enquiry, either by taking professional advice, or consulting larger tables. As an example of the case mentioned, suppose we ask for the value of an annuity of 1*l.* continued for 12 years, interest being at 4 per cent. We find in Table I., column 4 per cent.

For 10 years	8.111
" 15 "	11.118
Difference	3.007

Since 5 years adds 3.007 to the value of the annuity, every year will add about one-fifth part of this, or .601, and 2 years will add about 1.202. This, added to 8.111, gives 9.313. The real value is more near to 9.385, and the error of our table is .07 out of 9.313, or about the 133rd part of the whole. The higher we go in the table, the less proportion of the whole will this error be.

The last line in Table I. gives the value of the annuity of 1*l.* continued for ever: for example, at 5 per cent., the value of 1*l.* for ever, or, as it is called, a *perpetuity* of 1*l.*, is 20*l.* This is the sum which at 5 per cent. yields 1*l.* a year in interest only, without diminution of the principal. We see that an annuity for a long term of years differs very little in present value from the same continued for ever: for example, 1*l.* continued for 70 years at 4 per cent. is worth 23.395*l.*, while the perpetuity at the same rate is worth only 25*l.* Hence the present value of an annuity which is not to begin to be paid till 70 years have elapsed, but is afterwards to be continued for ever, is 1.605 at 4 per cent.: which sum improved during the 70 years, would yield the 25*l.* necessary to pay the annuity for all years succeeding.

TABLE IV.—Amount of an Annuity of One Pound.

Y.	3 p.c.	3½ p.c.	4 p.c.	5 p.c.
1	1.000	1.000	1.000	1.000
2	2.030	2.035	2.040	2.050
3	3.091	3.106	3.122	3.153
4	4.184	4.215	4.246	4.310
5	5.309	5.362	5.416	5.526
6	6.468	6.550	6.633	6.802
7	7.662	7.779	7.898	8.142
8	8.892	9.052	9.214	9.549
9	10.159	10.368	10.583	11.027
10	11.464	11.731	12.006	12.578
15	18.599	19.296	20.024	21.579
20	26.870	28.280	29.778	33.066
25	36.459	38.950	41.646	47.727
30	47.575	51.623	56.085	66.439
40	75.401	84.550	95.026	120.800
50	112.797	130.998	152.667	209.348
60	163.053	196.517	237.991	353.584
70	230.594	288.938	364.290	588.529

In this Table we see what would be possessed by the receiver of an annuity at the end of his term, if he put each year's annuity out at interest so soon as he received it. For example, an annuity of 1*l.*, in 40 years, at 5 per cent., amounts to 120.8*l.*, which includes 40*l.* received altogether at the end of the different years, and 80.8*l.* the compound interest arising from the first year's annuity, which has been 39 years at interest, the second year's annuity which has been 38 years at interest, and so on, down to the last year's annuity, which has only just been received. When the annuity is payable half-yearly, or quarterly, its present value is somewhat greater than that given in the preceding Table. For the annuitant, receiving certain portions of his annuity sooner than in the case of yearly payments, gains an additional portion of interest. Since 4 per cent. is 2 per cent. half-yearly and 1 per cent. quarterly, and since every term contains twice as many half-years as years, and four times as many quarters, it is evident that an annuity of 100*l.* a-year, payable half-yearly, at 4 per cent., for 10 years, is the same in present value as one of 50*l.* per annum, payable yearly, at 2 per cent., for 20 years. Again, 100*l.* a-year, payable quarterly for 10 years, money being at 4 per cent., is equivalent to an annuity of 25*l.*, payable yearly for 40 years, money being at 1 per cent.

The principles on which the calculation of life annuities

depends will be more fully explained in the articles PROBABILITY and MORTALITY. Let us suppose 100 persons, all of the same age, buy a life annuity at the same office. Let us also suppose it has been found out, that of 100 persons at that age 10 die in the first year, on the average, 10 more in the second year, and so on. If then it can be relied upon that 100 persons will die nearly in the same manner as the average of mankind, or at least that in such a number, the longevity of some will be compensated by the unexpected death of others, the fair estimation of the value of a life annuity to be granted to each may be made as follows. To make the question more distinct, let us suppose the bargain to be made on the 1st of January, 1833, so that payment of the annuities is due to the survivors on new-year's day of each year. Moreover let each year's annuity be made the subject of a separate contract. The first question is, what ought each individual to pay in order that he may receive the annuity of 1*l.*, if he survives, in 1834? By the general law of mortality, we suppose that only 90 will remain to claim, who will, therefore, receive 90*l.* among them, the remaining 10 having died in the interval. It is sufficient, therefore, to meet the claims of 1834, that the whole 100 pay among them, January 1, 1833, such a sum as will, when put out at interest, (suppose 4 per cent.,) amount to 90*l.* on January 1, 1834. This sum is 86.654*l.*, and its hundredth part is .86654*l.*, which is, therefore, what each should pay to entitle himself to receive the annuity in 1834. These will be only 80 to claim in 1835, and, therefore, the whole 100 must among them pay as much as will, put out at 4 per cent. for 2 years, amount to 80*l.* This sum is 73.968*l.*, and its hundredth part is .73968*l.*, which is, therefore, what each must pay, in order to receive the annuity, if he lives, in 1835. The remaining years are treated in the same way, and the sum of the shares of each individual for the different years, is the present value of an annuity for his life. We must observe, that in the term *value of an annuity*, it is always implied that the first annuity becomes payable at the expiration of a year after the payment of the purchase money.

The value of a life annuity depends, therefore, upon the manner in which it is presumed a large number of persons, similarly situated with the buyer, would die off successively. Various Tables of these *decrements of life*, as they are called, have been constructed, from observations made among different classes of lives. Some make the mortality greater than others; and of course, Tables which give a large mortality, give the value of the annuity smaller than those which suppose men to live longer. Those who buy annuities would, therefore, be glad to be rated according to tables of high mortality or low expectation of life; while those who sell them would prefer receiving the price indicated by tables which give a lower rate of mortality. In insurances the reverse is the case: the shorter the time which a man is supposed to live, the more must he pay the office, that the latter may at his death have accumulated wherewithal to pay his executors. We now give in Table V, the values of annuities according to three of the most celebrated Tables.

TABLE V.—Present Value or Purchase-money of a Life Annuity.

Age.	Northampton.			Carlisle.			Gov. M. Gov. F.	
	3 p.c.	4 p.c.	5 p.c.	3 p.c.	4 p.c.	5 p.c.	4 p.c.	4 p.c.
0	12.3	10.3	8.9	17.3	14.3	12.1		
5	20.5	17.2	14.8	23.7	19.6	16.6	19.3	20.0
10	20.7	17.5	15.1	23.5	19.6	16.7	18.8	19.7

The first of these is calculated from the Northampton Table, formed by Dr. Price, from observations of burials, &c.,

than the fact, and the average accumulations would be greater, from young ages considerably greater, than those shown in the preceding table

We have seen that the security of the method for estimating the value of life annuities, depends upon the presumption that the average mortality of the buyers is known. This average cannot be expected to hold good, unless a large number of lives be taken. Therefore, the granting of a single annuity, or of a few annuities, as a commercial speculation, would deserve no other name than gambling, even though the price demanded should be as high as that given in any tables whatsoever.

In the preceding tables, we would again remark, that our object has been simply to furnish the means of giving a moderately near determination of a few of the most simple cases. We should strongly recommend every one not to venture on important transactions, without professional or other advice on which he can depend, unless he himself fully understands the principles on which tables are constructed. The liability to error, even in using the most simple table, is very great, without considerable knowledge of the subject; and most cases which arise in practice contain some circumstances peculiar to themselves, which have not and could not have been provided for in the general rules.

The following references to works on this subject may be found useful.

ANNUITIES CERTAIN. 1. *Smart's Tables of Interest, &c.* London, 1726. There is an edition published in 1780, which is said to be very incorrect. The values for the intermediate half years given in this work are not correctly the values of the annuities on the supposition of half yearly payments; in other respects it is to be depended upon. 2. *Corboux, Doctrine of Compound Interest, &c.* London, 1825. 3. *Baily, Doctrine of Interest and Annuities.* London, 1808. *Smart's Tables* are republished in this work from the correct edition. Works on *life-annuities* generally contain principles and tables for the calculation of annuities certain.

LIFE ANNUITIES. 1. *Price, Observations on Reversionary Payments, &c.* Edited by W. Morgan, London, 1812. (Seventh Edition.) 2. *Baily, on Life Annuities and Assurances.* London, 1810. 3. *Milne, on the Valuation of Annuities and Assurances, &c.* London, 1815. 4. *Morgan, on the Principles of Assurance, Annuities, &c.* London, 1821. 5. *Davies' Tables of Life Contingencies.* London, 1825. 6. *Finlaison, on the Evidence and Elementary Facts on which Tables of Life Annuities are Founded.* Printed by the House of Commons, 31st March, 1829. 7. *Gompertz, Estimation of the value of Life Contingencies, in Philosophical Transactions,* 1820.

ANNULET, in architecture. This term is applied to the small eccentric rings or bands which enrich the lower part of the moulding of the Doric capital, just where it falls into, or grows out of, the top of the shaft, or trachelium. It is formed from the Latin word signifying a ring.

ANNULUS, the geometrical name of a ring, or solid formed by the revolution of a circle about a straight line exterior to its circumference as an axis, and in the plane of the said circle.

To find the surface of a ring, measure the interior and exterior diameters in feet or inches, &c. Multiply together the sum and difference of these diameters, and multiply the product by 2.4674011, taking as many decimals as may be thought necessary. For common purposes it will be sufficiently exact to divide 200 times the product of the sum and difference twice successively by 9. If still greater correctness be required, subtract from the last result its 500th part. The result will be the number of *square* feet, or inches, &c., in the surface of the ring.

To find the solid content of a ring, measure the outer and inner diameters as before, multiply together their sum and the square of their difference, and multiply this product by .3084251. For common purposes, it will be sufficient to annex three ciphers to the product of the sum and the square of the difference, and to divide by 3242. The result will be the number of cubic feet or inches, &c. in the ring.

ANOA, a species of ruminating animal, so very imperfectly known, that zoologists are undetermined whether to consider it as an antelope or a species of buffalo. This uncertainty arises from the fact, that though the animal has been noticed for many years, only a few fragments of skulls and horns have been hitherto brought to Europe, and even these too imperfect to acquaint us with the zoological characters of the animal. Judging, however, from these

materials, the anoa would really appear to be a species in many respects intermediate between the buffaloes and antelopes, as at present defined; agreeing with the former in the form of its horns, and with the latter in their position.

Mr. Pennant is the first naturalist who has mentioned this animal, but he has given no account of its characters, and merely relates, that it is about the size of a middling sheep, is wild and fierce, and resides in large herds among the rocky mountains of the island of Celebes. He considers it as a small species of wild buffalo, and adds, that it is captured only with great difficulty, and is so fierce in confinement, that some of these animals, belonging to Governor Loten, in one night ripped up the bellies of fourteen stags which were kept in the same paddock with them. The next author who mentions the anoa from original documents or personal observation, is Colonel Hamilton Smith, who in the fourth volume of Griffith's translation of the *Règne Animal*, describes the head and horns, and considers the animal as a species of antelope. Colonel Smith's fragment was brought from Celebes by the late Dr. Clarke Abel, who obtained it on his return from China in the suite of Lord Amherst; but since that period various other heads have been brought to Europe, some of which are deposited in the British Museum, and in the collection of the London Zoological Society. The

[Horns of Anoa.]

horns are erect, perfectly straight and in the plane of the forehead; they are about the same length as the head, that is, about nine or ten inches, strongly depressed or flattened in front, of nearly the same breadth till within three inches of the extremities, whence they are rather attenuated to the tips which are bluntly pointed, and irregularly wrinkled, or rather crumpled throughout the greater part of their length. The head is long and narrow, terminating in a broad muzzle, and all the characters so different from those of antelopes, that we prefer, in the present state of our knowledge, describing the animal under its native name of anoa, to the risk of originating future error by associating it with a genus to which it appears to bear but a very remote analogy.

ANODYNES, from the Greek *ἀνόδυνος* (*anódunos*), which sometimes signifies, 'that which relieves from pain.' We may consider pain as an intimation of some derangement of the system, the continuance of which would be hurtful. It therefore prompts us to take measures to remove the causes of it, which being done, the pain generally ceases. But as pain itself, from the inconvenience and suffering which it occasions, frequently aggravates the disease of which it is the accompaniment, it becomes necessary to employ means to lessen or suspend it, even though we should not be able to control the disease: these means are termed *anodynes*, and are either applied externally, or given internally.

The seat of pain is evidently in the nervous system, but its cause and origin appear to be intimately connected with the state of the circulating system, particularly with the quantity of blood contained in the arteries, and the degree of force and rapidity with which it passes through them. Hence pain may be said to be of two kinds; that which occurs when the blood stagnates in the extreme vessels, or capillaries, while the larger vessels propel it with increased force, or the state termed *inflammation*: and that which occurs when there is a deficiency of blood

in the extreme vessels, from the action of the large vessels being too feeble to propel it, as happens after long abstinence from food, or other causes of exhaustion—such as prolonged suckling of infants by mothers. The discrimination of these two kinds of pain is of great practical importance; for while the first will be relieved by bleeding and anodynes, the second will be greatly aggravated by the employment of either of these means. It is therefore to the former that the use of anodynes must be limited, in which they appear to be productive of benefit in two ways: first, by rendering the nerves of the part less sensible; and, secondly, by diminishing the violence with which the large vessels propel the blood, when the anodynes are given in sufficient quantity to influence the brain, and through it, by a process extremely complex, which we need not explain here, the contractile power of the heart and arteries. As most of the articles termed anodynes have a powerful influence over the brain, they generally produce sleep, if given in a large dose: hence they are also denominated *hypnotics*; and from causing insensibility, they are also denominated *narcotics*. The knowledge of their possessing this power should lead us to observe great caution in their administration, lest by an over-dose we should produce a fatal coma, or very profound sleep, from which the patient might never be roused.

It deserves also to be mentioned, that their frequent repetition produces an injurious effect on the frame, particularly on the nervous system, and function of nutrition; we should therefore carefully guard against acquiring a habit of having recourse to them on slight occasions, or without the sanction of a competent authority. The opium-eater not less certainly induces disease, and brings himself to an untimely end, than he who indulges in ardent spirits.

The substances used as anodynes are, with one exception, derived from the vegetable kingdom, and will be further treated of under the names of the plants which produce them. They are Opium, Hyoscyamus, or *Henbane*, Solanum Dulcamara, or *Woody Night-shade*, Atropa Belladonna, or *Deadly Night-shade*, Hydrocyanic, or Prussic acid, and Carbonic-acid-gas applied in the yest poultice, and other forms.

ANOLIS, in zoology, a genus of saurian reptiles, belonging to that section of the iguanian family which Baron Cuvier distinguishes by having teeth in the palate of the mouth as well as in the maxillary bones. They are readily distinguished from the iguanas, properly so called, the basilisks, and other genera of this division, by the peculiar form of the antepenultimate phalange of the toes, which is flattened beneath, and furnished with a kind of pad or cushion, grooved or striated transversely, and serving to make the animals adhere more firmly to those substances which they grasp in walking. In this particular point of their structure the anolis approach the geckoes, but it does not enable them to exercise the singular power of walking with the legs uppermost, like flies on a ceiling, which some of these reptiles possess. The toes, however, are much longer and better separated than those of the geckoes, and the claws, instead of being short and flattened, are long, crooked, and sharp-pointed. The body and tail are long and slender, as are also the legs, particularly those behind, which are rather longer than the fore legs; each foot has five toes. The whole body and tail, both above and below, are covered irregularly with small round scales, which give the skin a granulated appearance like that of fine shagreen. The head is long and straight; the forehead and face flattened and covered with numerous little pentagonal and hexagonal scales; the tongue is fleshy, short, round, undivided at the point, and not protractile, being almost throughout its whole length attached to the under jaw. The tail is in all cases as long or longer than the body more or less compressed on the sides, with a few slight plies or indistinct foldings, each comprising two or three circular rows of scales, and in some species provided with a crest supported by the erect spinous processes of the caudal vertebrae. The teeth, as well maxillary as palatal, are small, sharp, and serrated; and the skin of the throat forms, at least in the greater number of species, a loose hanging bag, which is capable of being dilated or distended with air at the will of the animal. Finally, the ribs of the opposite sides are united in front, and form complete circular hoops round the body.

The anolis are entirely an American genus, and seem, in many respects, to supply, in the New World, the place which the chameleons occupy in the Old. The colours of their

skins change with the same or even greater rapidity, especially on the loose skin of the throat, which is constantly distended when these animals are actuated by strong passions, either of fear, anger, or love, and in this state assume an endless succession of ever-varying hues. They differ from the chameleons, however, in their more slender and graceful proportions, and in the great activity of their movements, displaying all the restlessness and celerity of the common green lizard of Europe. They frequent woody and stony situations indifferently, climb and leap with such swiftness and facility that their pace has been compared to the flight of a bird; and when overheated or fatigued by their exertions, will stop, open their mouths, and pant like a tired dog. They are extremely timid and harmless; feed for the most part upon flies and other small insects, though M. Cuvier found the stomach of one species filled with berries; and though often inhabiting the neighbourhood of marshes and other moist situations, do not appear to be aquatic. There are two small subgenera, distinguished from one another by the presence or absence of the carinated crest on the upper surface of the tail. The first of these divisions, comprehending those which have this crest, consists of a number of species definitely characterised by M. Cuvier, but formerly confounded under the denominations of *Lacerta principalis* and *Lucerta bimaculata*. The principal are.

1. The *Anolis velifer*, of Baron Cuvier, of a beautiful dark

[*Anolis velifer*.]

ashy blue colour, and perhaps the largest of the whole genus, the body measuring a foot in length, and the tail being about half as long again. The crest extends along the top of the tail for half its length from the origin, and is supported by from twelve to fifteen rays; the loose skin beneath the throat extends from the chin even to the belly, and when not distended forms a longitudinal fold along the whole under surface of the animal; and the food, from the observation of Baron Cuvier, would appear, at least occasionally, to consist of berries and other vegetable substances. It inhabits Jamaica and the Antilles generally, preferring the woods to the open country, and lodging in decayed trees or small crevices in the ground, where the female likewise deposits her eggs. It is incessantly in motion, and when pleased frequently emits a low but acute chirp; though harmless and extremely timid, it possesses a considerable share of curiosity, and allows itself to be readily caught in little rush snares, which children in the West Indies amuse themselves by placing in its haunts, alluring it from its concealment by imitating its voice.

2. The *Anolis bimaculata*, of Sparrman, little more than half the size of the former species, but with the same general form and habits, and with a similar crest upon the first half of the tail. The general colour is a greenish blue, clear on the top of the head and neck, but mixed with dark brown on the body, tail, and extremities, and marked with numerous small black spots on the head and sides, and two large ones on the shoulders, from which it derives its specific name. It is found in North America, from Pennsylvania to the shores of the Gulf of Mexico, and in the Antilles.

The second subdivision of the genus anolis consists of species without a carinated crest on the tail, but in no other respect differing from those already described. Of these the principal are,

3. The *Anolis equestris* of Merrem, of which the tail, more flattened on the sides than in the following species, still retains a slight indication of the crest which distinguishes those of the former division. The body of this species mea-

tures about a foot in length, and the tail is nearly half as long again. It is of a light tawny colour, agreeably clouded in different parts with blotches of an ashy lilac tinge, but so blended and shaded off with the ground colour of the body, as never to assume the form of distinct spots. The skin of the throat is white, and a band of the same colour passes

[*Anolis Equestris*.]

over each shoulder, and runs parallel to the back almost half way down each side. Though the crest on the tail does not appear externally, yet the spinous processes of the caudal vertebræ have the same elevated form as in the anolis of the first subgenus, and appear to be concealed only by the more fleshy form of the tail. The habitat of this species has not been exactly determined.

4. The *Anolis cepedii* of Merrem is a pretty little species, found likewise in the Antilles, about half the size of the last, of a green colour, with a short muzzle spotted with brown, and, except in the absence of the crest on the tail, very similar to the *Anolis bimaculata*. Its habits are well described by Lacepède.

5. *Anolis lineatus* of Daudin resembles the last species in its pure bright green colour, but it is rather larger, and is marked along each flank with two parallel lines of oblong black spots, the upper of which passes over the arms and thighs, and the under between the shoulders and hips. It inhabits different parts of South America.

6. The *Anolis bullaris* of Merrem, first described by Catesby in his *Natural History of Carolina*, under the name of green lizard, is a very beautiful species, of a greenish gold colour, particularly distinguished by a black band on the temples, and the elongated and flattened form of its muzzle. This and the two last-described species, as well as various others described by Daudin, prince Maximilian, and others, have the loose skin of the throat of a beautiful cherry colour when distended, and change from one hue to another with a facility and rapidity truly astonishing.

ANOMALISTIC YEAR, the interval which elapses between two successive times when the earth is at the least distance from the sun. If the earth's orbit were a perfect ellipse, this would be exactly equal to the common or tropical year; the orbit is, however, more nearly represented by an ellipse of which the axis revolves through $11''.8$ in a year. That is, if we imagine a star which is always eclipsed by the sun's centre, at the moment when the earth is at its least distance, that star must follow the sun at the rate of $11''.8$ in a year, or a revolution in 108,000 years, in round numbers. The anomalistic year, or the time between two successive eclipses of the supposed star, is 25 minutes longer than the tropical year, being 365 days, 6 hours, 13 minutes, 45 seconds.

ANOMALY, (in Astronomy,) a term derived from the Greek *ἀνόμαλος* (*anómalos*), unequal or irregular, and applied in astronomy to the angle through which the radius drawn from a planet to the sun, has moved with the planet from the time when the planet was at its least distance from the sun. The term was applied to this angle, as being the angle whose irregularities were first observed; though it must be confessed that this is not a happy specimen of mathematical nomenclature.

Let S be the position of the sun, in the focus of the ellipse described by the planet, A the *perihelion*, or point of least distance from the sun, A P M the ellipse described by the planet, A Q M the circumscribed circle, P the place of the planet, and Q P N a perpendicular to the axis A M. Let C be the centre of the ellipse and circle. The planet

moves quickest at A, and slowest at M. Conceive a fictitious planet Z to move round the ellipse A P M, with the average motion of the real planet, so as, without varying its motion, to make the angle A S Z increase uniformly, and to describe the whole revolution in the same time as the real planet. Then, for the moment when the planet is at P, the angle A S P is called the *true anomaly*, A S Z is called the *mean anomaly*, and A C Q the *eccentric anomaly*. In speaking of the sun or the moon, it is the earth which is supposed to be at S, and the sun or moon at P. Also, in speaking of the satellites of Jupiter or Saturn, the planet is supposed to be at S, and the satellite at P. For a double star, one star is supposed to be at S, and the other to revolve round it.

The determination of either two anomalies from the third, is a problem of considerable difficulty, the discussion of which may be found in any mathematical work on astronomy.

ANONA'CEÆ, a natural order of plants consisting of tropical or subtropical trees and bushes, that usually abound in a powerful aromatic secretion, which renders the flowers of some highly fragrant, the leaves of others a grateful perfume, and the dried fruits of many so highly aromatic as to vie with the spices of commerce; among these last is the *Æthiopian pepper* of the shops, which is yielded by the fruit of *Uvaria aromatica*. Of others of this order, the fruit is succulent and abounds in a delicate juice, which renders it a pleasant article of food: under the name of sour sop, sweet sop, and custard-apple, many kinds are

[*Annona*.]

[*Annona squamosa*, or sweet sop.]

cultivated in the West Indies and South America. Finally, the bark of some separates readily into fibres which make excellent cordage: a large tree called, in Brazil, pindaiba, and by botanists *xylopia sericea*, is advantageously employed for this purpose.

The natural order anonaceæ is known from all other dicotyledonous orders by its flowers having the calyx and sepals arranged in threes, a number of carpella occupying the centre, as in a ranunculus, and by the curious circumstance of their albumen, which here constitutes the bulk of the seed, being what is called ruminated, that is, perforated in all directions by twisting and crossing passages, like the nutmeg.

The preceding cut will give an idea of the structure of this order:—1. A calyx opened, the petals having fallen away, showing the arrangement of the stamens and carpella in the inside of the flower; 2. a stamen; 3. a seed; 4. the same cut in half, to show the ruminated albumen; 5. the embryo; 6. a ripe fruit, much less than the natural size; the projections on its surface are the points of the carpella which grow together into one fleshy mass, as in the raspberry; 7. a view of the same fruit cut in half.

Of the eatable fruited kinds above referred to, the most remarkable are the sweet sop, sour sop, and cherimoyer; all species of the genus *Anona*.

The sweet sop, *Anona squamosa*, is often only a small bush, growing in all the West Indian islands, where it bears a greenish fruit covered with scales, and having the appearance of a young pine cone. Its skin is half an inch thick, and contains an abundance of thick, sweet, luscious pulp; in many parts of the Indian Archipelago, it is a favourite fruit.

The custard apple, *Anona reticulata*, is an inferior kind, resembling the foregoing, but forming a larger tree, and having a much larger dark-brown fruit, the surface of which is netted all over. The pulp is yellowish, or reddish, and of about the consistence of custard.

The sour sop, *Anona muricata*, forms in the West Indies a picturesque small tree, resembling a great bay-tree. The flowers are yellow, and have an unpleasant odour. The

green, but hoary, with short down, and very blunt. It forms a small tree about twelve or fourteen feet high, and is exceedingly valued in Peru, where it is cultivated on account of the excellence of its fruit. The flowers are very fragrant; the fruit heart-shaped, greyish-brown, or black, when ripe, with a scaly rind; the fruit is white, sweet, and rich. In the garden of the archbishop of Granada, in Spain, there were specimens of this which fruited every year, and were found to be really excellent even to a European palate.

The following spirited sketch, by Mr. Westall, of the appearance of the sour sop tree, will give some idea of the effect it would be likely to produce on the scenery of the country where it grows.

[*Anona muricata*, or Sour Sop.]

fruit is often as heavy as 2 lb., or even 3 lb.; it is covered all over with weak prickles; its skin is yellowish-green, and very thin; its pulp is more like pith, is as white as milk, and is sweet, mixed with a most agreeable acid.

The cherimoyer, *Anona cherimolia*, is easily known from the preceding by its leaves not being shining and bright-

ANOPLATHE'RIMUM (from ἀνπλατήριον, *ἀν* privative, *πλάττω*, and *θηρ*, that is, a beast without offensive arms or tusks), in fossil zoology, a genus of extinct pachydermatous quadrupeds, discovered and characterized by Baron Cuvier. The bones of these singular inhabitants of a former world, occur in great quantities, mixed with those of the *palaotherium*, another extinct genus of the same order, likewise described by M. Cuvier, in the gypsum or plaster quarries in the neighbourhood of Paris, and they are occasionally, though more rarely, met with in the neighbourhood of Orleans and Genoa. It was only after researches continued for many years, that M. Cuvier succeeded in uniting the disjointed and broken fragments of bones belonging to the different parts and members of this genus, so as to reconstruct the complete skeleton of the animal, and obtain a definite and correct idea of its external form and appearance. The great labour and admirable skill which he has displayed in these profound and difficult inquiries were, however, finally crowned with success, and rewarded him not only with a knowledge of six distinct species, but even enabled him, in some instances, to depict their external forms, and infer, by an admirable chain of inductive reasoning, their probable habits and economy. Without entering into the minute and profound osteological comparisons which engaged the attention of M. Cuvier, and which those who desire to pursue the subject farther will find at length in the third volume of the *Ossemens Fossiles*, we shall here give the result of his inquiries, and endeavour to supply a correct idea of the form and affinities of these antediluvian inhabitants of our earth.

The first character in which the anoplotheria differ essentially from all other pachydermata, whether extinct or recent, is found in the number and arrangement of their teeth, which consist of six incisors, two canines, and fourteen molars in each jaw, making in the whole forty-four teeth. These, as in the human subject, are arranged in a continued

and uninterrupted series, without any vacancies between the molars or incisors and the canines, a circumstance peculiar to this genus of animals among the pachydermata, and which, besides man, it shares only with the shrews and hedgehogs, mammalia, in all other respects, widely different. The canines, moreover, are perfectly similar in form and appearance to the incisors, and might easily be mistaken for lateral teeth of this description, did not their situation in the jaw, beyond the maxillary suture, prove their real nature. The four posterior molars resemble those of the rhinoceros and palæotheria, that is to say, they are quadrangular in the upper jaw, and marked in the lower, with a double or triple crescent of enamel, which penetrates their substance and shows itself on the crowns in the form of salient ridges.

This formation of the organs of mastication, intimately connected as these organs necessarily are with the food and alimentary canal, demonstrate most unequivocally that these animals fed upon vegetable substances, and that, in all probability, they differed but little in this respect from the tapirs and rhinoceroses at present existing. Other details of their structure, about to be noticed, will confirm these analogies, and afford us a still clearer insight into their habits and economy.

The second important character of the anopletheria which must have exercised a very decided influence upon their habits arises from the conformation of the extremities. These, as in ruminating animals, were terminated by two toes, enveloped in small hoofs, sometimes without accessory or false hoofs behind, as in the camels and lamas, sometimes with one or even two small lateral toes of this description, as in the pecaries, but the bones of the metacarpus and metatarsus respectively corresponding to these two toes were not united into a single canon, as they invariably are among the ruminantia, and this is in reality the principal difference between the extremities of the latter animals and those of the anopletheria. It is to be observed, however, that this character is not peculiar to the ruminants; the pecaries, or indigenous hogs of South America, have likewise the metacarpal and metatarsal bones soldered into a single piece, exactly resembling the canon bone of the sheep or deer, and in this respect, are intermediate between the orders of the ruminantia and pachydermata. The stomachs of the pecaries likewise partake of the complication characteristic of the former group, from which, on the other hand, the camels, in all other respects true ruminants, differ widely both by the form of their feet, and the number and arrangement of their incisor teeth. These animals are, in fact, far more anomalous among the ruminants than the pecaries are among the pachydermata, and it is to their extremities, particularly, that the construction of the corresponding parts of the anopletheria most nearly approximates. The structure of the carpus and tarsus are precisely the same in both genera; the scapoid and cuboid bones, which are soldered together into a single piece in all the other ruminants, being separate in the camels and lamas, as they invariably are in the anopletheria and other pachydermata. These analogies prove that the anopletherium, which its teeth have already shown to have been essentially a pachydermatous quadruped, approached in many of its characters to the ruminantia of the existing creation, partaking, on the one hand, of the characters of the camels and lamas, and on the other of those of the rhinoceroses and pecaries. In the less prominent details of organization, however, the different species of anopletheria present peculiarities which have induced Baron Cuvier to distribute them in three subgenera. In all, the prolongation of the nasal bones clearly shows that the anopletheria were not furnished with trunks like the elephants, tapirs, and palæotheria; and their head altogether, judging from the form of the skull, appears to be intermediate between that of the horse and that of the camel. The first subdivision comprehends those species which M. Cuvier calls

Anopletheria proper: they are distinguished by having all the lower molars marked by double or triple crescents in a longitudinal direction, without salient tubercles; and by a third, or supernumerary hoof on the fore-feet. This division comprehends two species, differing from one another principally in point of size, the one (*A. commune*) being about the size of the ass, and the other (*A. secundarium*) about that of the hog. These animals were low on the limbs, probably like the tapirs, but their long and powerful tail, equalling the body itself in length, made them still more

essentially aquatic animals. The great size of their members, the depressed and heavy proportions of their bodies, and their long tails compressed horizontally at the base, must have given them much of the external form of the otter; but they resorted to the lakes and marshes of the antediluvian world, not for the purpose of preying upon other animals, but in search of aquatic plants, whilst the depressed form of their tails shows that they must have swam and plunged with greater ease and facility than either the tapir or hippopotamus. Like these animals, their ears were probably short and erect, and their bodies sparingly covered with hair, as in all the existing pachydermata. The following outline conveys a just idea of the external figure of this animal, as drawn from the skeleton by M. Cuvier.

[*Anopletherium commune*.]

The subgenus *xiphodon* differs from that just described in having the inferior molars tuberculous, and being without the additional or false hoof on the fore-feet. It contains but a single species (*A. gracile*), which, judging from the length and smallness of its limbs, and the elevation of the tarsus, must have presented in every respect a complete contrast to the *A. commune*, exhibiting the light form and graceful proportions of the gazelle. Its course must necessarily have been rapid, and probably unembarrassed by a long tail; and instead of resorting habitually to the rivers and ponds, like the former species, it must have been confined to the dry land, and, probably like the gazelles and antelopes, fed upon dry aromatic herbs, and was provided with long moveable ears to warn it of the approach of danger. M. Cuvier likewise possessed a skeleton of this species, nearly perfect, and has furnished the following outline of its external form.

[*Anopletherium gracile*.]

The third subgenus, *dichobunes*, contains three species, all established from the observation of detached bones, and of the actual forms of which it is consequently impossible to give a correct idea. They differed from the species contained in the two former subdivisions, principally by having a small additional or false hoof both on the fore and hind feet, and this character is so well marked in all the three subgenera of M. Cuvier, that, besides other considerations, it would suffice, among existing animals, to distinguish three separate genera, and perhaps should do so in the present instance. The *dichobunes* were all of small stature: the largest of the three known species (*A. leporinum*) was about the size of a hare; the other two (*A. murinum* and *A. obliquum*), about that of the guinea-pig, were in all probability the smallest of hoofed quadrupeds. M. Cuvier supposes them to have been the hares and rabbits of the antediluvian world, but their whole structure seems to approximate them more correctly to the musks of the present time, and they probably differed little from these animals either in form or habits.

ANQUETIL DU PERRON (Abraham Hyacinthe) was born at Paris on the 7th December, 1731. He received his early education in that capital, where he soon displayed a predilection for the study of the Hebrew language and literature. M. de Caylus, then bishop of Auxerre, induced him to study divinity, for which purpose Anquetil visited two theological seminaries. But his fondness for the literature of the East, especially the Arabian and Persian, did not allow him long to pursue his theological studies, and he returned to Paris, where he made use of the ample stores of oriental learning collected in the Bibliothèque du Roi. Accidentally, a fac-simile of a few pages of the *Vendidad-Sadé* came under his eyes, and this circumstance first turned his attention and inquiries towards India and the Persia. A French army was just at that time fitted out for India. Anquetil resolved to avail himself of this opportunity to visit India, and enrolled himself as a private soldier, in which capacity he quitted Paris on the 7th of November, 1754. It was only after his departure that his friends obtained for him a small pension (500 livres) from the French government, to assist him in the pursuit of his inquiries. Anquetil disembarked at Pondichery, on the Coromandel coast, the 10th of August, 1755; hence he proceeded to Chander-nagor, in Bengal, but was disappointed in his hope of finding there an opportunity of learning the Sanskrit language. At this place he was taken ill, and the capture of Chander-nagor by the English soon obliged him to leave, and return on foot, by a journey of a hundred days, to Pondichery, where he embarked on board a vessel which was bound for Surat, but landed at Mahé, on the Malabar coast, and continued his way by land, and again on foot. At Surat he became acquainted with some *desturs*, or Parsi priests from Guzerat, whose assistance enabled him to make the necessary preparations for the translation of the Zend Avesta, which he published after his return home. The progress of the British power induced Anquetil to leave India. He embarked for Europe in an English ship, arrived at London, visited Oxford, and on the 4th of May, 1762, returned to Paris. The Abbé Barthélémy procured him an appointment in the Bibliothèque du Roi, and in 1763 he was elected a member of the Académie des Belles-Lettres. From this time Anquetil devoted himself entirely to literary labours. In 1771 he published his principal work, a translation into French of the *Zend Avesta*, or the sacred writings of the Parsis, attributed by them to Zoroaster. This work had scarcely appeared, when it was attacked with undeserved severity by Mr. (afterwards Sir William) Jones, in his *Lettre à M. A*** du P***, dans laquelle est compris l'Examen de sa Traduction des livres attribués à Zoroastre*. (London, 1771, 4to.) Jones himself seems to have subsequently felt that he went too far, when he declared the work translated by Anquetil a mere fabrication of modern times. But the question concerning the genuineness or authenticity and the exact date of these writings is not yet ultimately settled. A lithographed fac-simile edition of the beautiful manuscript of the most important of them, the *Vendidad-Sadé*, which Anquetil brought home from India, is now appearing at Paris; and several French and German Orientalists, especially Eugène Burnouf of Paris and Bopp of Berlin, have, by means of Anquetil's translation, analyzed the original language, and shown its close affinity to the Sanskrit. Of Anquetil's other works we shall here only notice his *Recherches Historiques et Géographiques sur l'Inde*, which he published in 1786; and his Latin interpretation of Dara Shekuh's Persian translation of the Sanskrit *Upnishads*, or ancient and sacred treatises on the theology of the Brahmans, which appeared under the title *Oupnekhatsive secretum tegendum*, &c. (Strasburg, 1804, 2 vols. 4to.) Anquetil died on the 15th of January, 1805. (The biographical notices in the above sketch of Anquetil's life are taken chiefly from the *Biographie Universelle*.)

ANQUETIL DU PERRON (LOUIS PIERRE), the elder brother of the subject of the preceding article. He was born at Paris in 1723, and having studied theology, was, at an early age, appointed director of the Episcopal Seminary at Rheims. From this place he was removed in 1759 to the Priory of La Roë in Anjou, and thence to that of director of the College of Senlis, which situation he held for ten years. He then became Curé of Château-Renard near Montargis, where he spent twenty years of his life, performing his sacred duties in a manner which greatly endeared him to his parishioners. The new ecclesiastical

arrangements made at the revolution transferred him from this village to that of La Villette near Paris; and here he remained till 1793; when, in the general proscription of the clergy, he was seized and thrown into the prison of St. Lazare. The catastrophe of the 9th Thermidor (27th of July, 1794) delivered Anquetil along with the other victims of the overthrown tyranny. He had before this been a corresponding member of the Academy of Belles-Lettres; and on the establishment of the Institute in 1795, he was nominated one of the members of the second class. He was soon after appointed to a place under government in the foreign office, and this he held till his death on the 6th of September, 1808, at the age of eighty-four. Anquetil had all his life been fond of literary occupation; and up to its close is said to have continued his early habit of studying regularly ten hours a day. He is the author of a considerable number of historical works, of which, however, only one or two are now held in much esteem. His best performance is considered to be a *History of the City of Rheims*, which appeared in three volumes, 12mo. in 1756-7. M. Felix de la Salle, however, is understood to have been conjoined with Anquetil in the composition of this work. His *Esprit de la Ligue*, which first appeared in three volumes, 12mo. in 1767, being a history of the troubles which distracted France after the death of Henry III., has also been several times reprinted. Another of his works is his *Précis de l'Histoire Universelle*, a considerable part of which was written in St. Lazare, and which was first published in nine volumes, 12mo. in 1797. This work has been translated into English, Spanish, and Italian, but is not regarded as having much merit. There is also a *History of France* by this writer in fourteen volumes, 12mo., the first of which appeared in 1805: he is besides the author of numerous papers published in the *Memoirs of the Institute*; and of an account of the life of his brother, the oriental scholar. (*Biographie Universelle*; *Biographie Nouvelle des Contemporains*; *Encyclopédie des Gens du Monde*, Paris, 1833.)

ANSBACH, ANSPACH, or ONOLZBACH, formed a portion of the old principality of Ansbach-Baireuth, in the southern part of Franconia, but it is at present merged in the circle of the Rezat, which surpasses every other province of the kingdom of Bavaria in relative population, trade, and manufactures. In more remote times, this principality was an appendage of the Burggraviate of Nuremberg, which fell to the house of Hohenzollern in the twelfth century, and subsequently passed into the possession of the Margraves of Brandenburg. It afterwards became the property of the collateral branch of Baireuth, and, on the extinction of that branch in 1726, descended to the subsequent Margraves of Ansbach-Baireuth. The last of this family, who intermarried with the celebrated Lady Craven, youngest daughter of Earl Berkeley, in 1767, ceded his inheritance to the King of Prussia, his feudal lord, on the 2d December, 1791. The latter, however, was compelled by the French emperor to relinquish it to him in 1806; and Napoleon shortly afterwards made it over to Bavaria, in exchange for Juliers and Berg. Baireuth, the other portion of the united principality, was also extorted from Prussia, after the disastrous conflict at Tilsit, and, by the same distributor of crowns and kingdoms, transferred to the Bavarian sovereign in 1809.

ANSBACH, formerly **ONOLZBACH**, the capital of the extinct principality of that name, and now the capital of the circle of the Rezat in Bavaria, lies in a fertile and richly-cultivated valley, traversed by the river Rezat, and is built round the confluence of that river with the Holzbach, 48° 12' N. lat., 10° 33' E. long., and about thirty miles south-west of Nuremberg. The town is embellished with handsome squares, and public, as well as private, buildings; the regularity with which the new town is constructed, combined with the attractive country which surrounds it, render Ansbach a pleasant residence. The palace of the former Margraves, a handsome structure in the Italian style, though at present a solitude, retains its gallery of paintings and library; and its grounds, which are laid out in the English taste, are still kept up for the recreation of the inhabitants. Ansbach is the seat of a court of justice and court of appeal, as well as of a Protestant consistory; it contains also one of the eighteen royal gymnasia, or high-schools, schools of design and music, and a society of arts and manufactures. The principal manufactures of the place are earthenware, tobacco, linens, cottons, woollens, and white-lead: the number of its inhabitants, which in 1825 was 14,000, is now between 16,000 and 17,000, and in this respect it ranks as

the seventh town in the Bavarian dominions. The holy fraternity of St. Gumbert, who showed something better than a monkish taste in selecting a site of so much natural beauty for their abiding-place, may be looked upon as the founders of Ansbach. Under its native princes, it gradually grew into a busy, thriving spot; but, at the present day, it partakes in no small degree of the character of a remote quarter in the old town, which has been, not inappropriately, christened '*Ennui*.' The last Margrave, whenever he could persuade himself to abandon the more seductive charms which England, France, and Italy presented, was accustomed to devote himself to the pleasures of the chase and table at his neighbouring seat, Triesdorf, which was better known among his subjects by the name of the 'Falcon's Nest,' and was in high repute throughout the continent for its breed of horses and cattle. The peasantry of Ansbach are distinguished by a singular costume, consisting of a long black frock, scarlet waistcoat with white buttons, black leather breeches, and a Lilliputian round hat. The women of Ansbach are accounted the loveliest and most lively of the Franconian females. Cronck, a dramatic, and Uz, a lyric, poet, who stand high in the estimation of their fellow-countrymen, were both of them natives of Ansbach, and a monument has been erected to the memory of the latter in the grounds attached to the palace. His translation of Anacreon is remarkable for its elegance and fidelity.

ANSELM, archbishop of Canterbury in the reigns of William Rufus and Henry I., commonly called St. Anselm, was by birth an Italian, and a native of Aosta, a town of the Alps belonging to the Duke of Savoy. He took the monastic habit in 1060, at the age of twenty-seven, at Bec in Normandy, where Lanfranc, afterwards archbishop of Canterbury, was prior. Three years after, when Lanfranc was promoted to the abbacy of Caen, Anselm succeeded him as prior of Bec, and when Herluin the abbot of that monastery died, Anselm became abbot of the house. Anselm came to England about A.D. 1092, by the invitation of Hugh Lupus, Earl of Chester, who requested his aid in sickness. Soon after his arrival, William Rufus, who was ill at Gloucester, also required Anselm's assistance, and finally nominated him (though with great difficulty of acceptance on Anselm's part) to the see of Canterbury, which had lain vacant so long, from Lanfranc's death in 1089, as to touch the king's conscience with remorse. Anselm, having first stipulated for the restitution of the possessions of the see as they had stood in his predecessor's time, was consecrated with great solemnity, December the 4th, 1093. In the following year, when William Rufus was endeavouring to wrest Normandy from his brother Robert, a stinted offer, as the king thought it, of 500*l.* was the first cause of the royal displeasure towards Anselm; followed by further discontent when Anselm desired leave to go to Rome to receive the pall from Pope Urban II., whom the king refused to acknowledge as pope, being inclined to favour the party of his competitor Guibert, or rather being desirous that Anselm should receive the pall from himself. At a great council held at Rockingham castle, when charges were made against Anselm, the majority of the bishops sided with the king, and renounced their canonical obedience to the archbishop, while the temporal barons supported him. During this conflict, Walter, bishop of Alba, the pope's nuncio, brought the pall into England, which it was at last agreed should be carried to Canterbury, and placed upon the altar of the cathedral, whence Anselm was to receive it as if it had been put into his hands by St. Peter himself. In short, the king pretended to be reconciled. He soon, however, took an opportunity of again quarrelling with Anselm for having furnished, as he alleged, an ill-equipped proportion of troops for the expedition against Wales. Anselm, now seeing no probability of terminating his disputes with the king, proposed a visit to Rome to consult the pope, but was personally refused the royal permission to depart. His resolution, however, was fixed: he went a second time to court to ask for leave, and was again refused, but gave his blessing to the king, and embarked at Dover. As soon as the king had ascertained that Anselm had crossed the channel, he seized upon the archbishoprick, and made every act of Anselm's administration void. The archbishop got safe to Rome, and was honourably received by the pope, whom he afterwards accompanied to Capua. Here he wrote a book upon our Saviour's incarnation; subsequent to which he assisted the pope at the synod or council of Bari, where he prevented Urban from excommunicating the king of England for his various and frequent outrages

upon religion. The king, however, by presents and promises, finally bribed the court of Rome to desert Anselm, who retired to Lyons, where (with the interval of an attendance at a council at Rome in 1099) he continued to reside till he heard of William Rufus's death, with that of Pope Urban shortly after. Henry I., immediately upon his accession, invited Anselm to return to England, but fearing his brother Robert's arrival as a competitor for the throne, he was crowned by another prelate. The archbishop was received in England with extraordinary respect both by the king and people, but refusing to be re-invested by the king, and to do the same homage with his predecessors, he again fell under the displeasure of the court; open rupture, however, was deferred till the return of the agents of both parties, who had been sent to Rome. In the interim Anselm summoned a synod to meet at Lambeth, in which it was determined that the king might lawfully marry Matilda, the eldest daughter of Malcolm king of Scotland, although she was generally reported to be a nun; he also rendered signal service to King Henry against his brother, the Duke of Normandy, who had landed at Portsmouth; and gave his aid in preventing some of the nobles of Henry's court from joining in revolt. The agents to Rome now returned. One of them refusing to dispense with Urban's canons, and the king refusing to yield his prerogative, the dispute was still kept up, and rather inflamed in consequence of the majority of the bishops and nobility siding with the king. It was now determined that fresh agents should be sent to Rome; but when they returned, the two parties disagreed as to the answer they had received from the pope; the king's bringing a verbal answer in addition to the written letter. After this, for a short period, the controversy was allowed to sleep. In 1102 another national synod was held under Anselm, at St. Peter's, Westminster, which was attended by the king and principal nobility. In the year following, at the request of the king and barons, Anselm himself took a voyage to Rome, to arrange, if possible, an accommodation; the king, at the same time, in distrust, despatching an agent of his own to the papal court, who arrived before the archbishop. The pope still continued inexorable; but wrote a ceremonious letter to the king, promising compliance in other matters, if the king would but waive the matter of investiture. Anselm, in chagrin, again took up his residence at Lyons; while a fresh embassy to Rome from the king was still more unsuccessful than the former, the pope levelling the heaviest censures of the church against different persons of the English court who had dissuaded the king from parting with the investitures. Anselm now removed from Lyons to the court of Adela, countess of Blois, the king's sister, who, during a visit which Henry I. made to Normandy, contrived an interview between him and Anselm, July 22, 1103, at the castle of L'Aigle, when the king restored to him the revenues of the archbishoprick, but refused permission for Anselm to return to England unless he would comply with the investiture. Anselm, still refusing, remained in France, retiring to the abbey of Bec; and though the English bishops, who till then had sided with the king, now changed their minds, and pressed Anselm to return, he refused, till he was further informed of the proceedings of the court of Rome. At length the ambassadors returned, and announced that the pope, adopting a middle course, refused to give up the investitures, but was willing so far to dispense, as to give leave to bishops and abbots to do homage to the king for their temporalities. This was in 1106. The king now invited Anselm to England, but the messenger finding him sick, the king himself went over into Normandy, and made him a visit at Bec, where all their differences were adjusted. Anselm, being recovered, embarked for England, and, landing at Dover, was received with extraordinary marks of welcome. To omit other circumstances of respect, it is stated that the queen herself travelled before him upon the road, in his return, to provide for his better entertainment. From this time, little that is remarkable occurred in the life of Anselm, excepting a dispute with Thomas, elected archbishop of York in 1108, who, wishing to disengage himself from dependency upon the see of Canterbury, refused to make the customary profession of canonical obedience. Before the termination of this dispute, Anselm died at Canterbury, April 21, 1109, in the seventy-sixth year of his age.

The works of Archbishop Anselm were published first at Nuremberg, folio, 1491; at Cologne in 1573, and 1612; at Lyons in 1630; by Father Gerberon, at Paris, in 1675,

reprinted in 1721; and again at Venice, 1744, in two volumes folio. In the library of Lyons there is a beautiful manuscript of his meditations and prayers. Some of his pieces in the Cologne edition of 1612, and the Lyons edition of 1630, are thought to be supposititious.

Anselm was a man of piety and learning according to the measure of the age in which he lived; but by promoting with zeal and obstinacy the ambitious views of the court of Rome, he involved both his king and country in many troubles, and set an example of opposition which was too well imitated by some of his successors. He was the first who restrained the marriage of the English clergy, by passing the ecclesiastical canons of the years 1102 and 1108. Eadmer the historian, who had been the archbishop's secretary, was the first who wrote his life; and there is another life of him by John of Salisbury, disfigured by the relation of many supposed miracles which the archbishop is said to have wrought. The canonization of Anselm took place in the reign of Henry VII. at the instance of cardinal Morton, then archbishop of Canterbury,—a singular mark of veneration for one who had been dead so long. (Godwin, *de Præsulibus*; *Biogr. Brit.* edit. 1778, vol. i. p. 205; Henry, *Hist. Brit.* b. iii. c. 2; Chalmers' *Biogr. Dict.* vol. ii. p. 280.)

ANSER, the goose, a genus of birds which M. Brisson, very properly as we think, separated from the genus *Anas* of Linnaeus. Brisson has been followed in this by Baron Cuvier, Vieillot, Lesson, Drapiez, and Fleming; while Latham adheres to Linnaeus, and Temminck confines *Anser* to a section of *Anas*. The following are M. Vieillot's characteristics, with some slight modifications. The bill shorter than the head, and higher than wide, but as thick as it is broad, in some species bulged at the base near the forehead, straight, rounded at the point, denticulated with conical and pointed lamellæ; the upper mandible is convex and unguiculated at the tip; the lower mandible is flat and rather narrow. The wings are of moderate length, and on some species furnished with tubercles. The legs are considerably longer, and more in the middle of the body than in *Anas*, and hence geese walk better than ducks. There is no enlargement at the base of the windpipe.

The species, twenty-eight in number, will be described under Goos.

ANSON, GEORGE, LORD, was the third son of William Anson, Esq., a gentleman of a good family, long established in Staffordshire. Anson's inclination to the seafaring life discovered itself early. It was his greatest pleasure to read and hear stories of eminent voyagers and admirals; his father, therefore, gave him such an education as was likely to foster and improve the natural bent of his genius. In 1722, he was made master and commander of the Weazel sloop, and the year following was raised to the rank of post-captain, and to the command of the Scarborough man-of-war. In this station in the profession, he was employed on various services, which he discharged with credit.

It was at the breaking out of the Spanish war that he first became an historical character. In 1740, he was appointed to the command of a small squadron, which was ordered to sail for the South Sea, a quarter where no attack was anticipated, to harass the coasts of Chili and Peru, and to co-operate occasionally with Admiral Vernon across the Isthmus of Darien. The scheme was well laid, but frustrated by unaccountable delays in the first instance, and afterwards by some unforeseen accidents. Anson was not able to sail until September; but the dilatoriness which retarded his departure till so late in the year was yet less culpable than the negligence which sent him out with ships ill-fitted for the

dangerous navigation on which he was bound. He doubled Cape Horn, in March 1741, after experiencing most tempestuous weather off that dangerous coast, in which his whole squadron was dispersed. He arrived, with only his own ship the Centurion, at Juan Fernandez, 33° 40' S. lat., 79° W. long., June 10, after suffering for near three months from a series of the most terrific storms, and from the ravages of the scurvy, which in that short time had carried off upwards of 200 from a crew of between 400 and 500 men, and left scarce enough of the remainder in health to work the ship. At that island he was rejoined by the remains of his squadron, consisting of the Gloucester man-of-war, a sloop, and a vessel, called in the phraseology of the times a pink, laden with provisions. His men were now reduced to the number of three hundred and thirty-five. With this small force he left Juan Fernandez in September kept the Spanish coast for eight months in continual alarm, made prize of several small vessels, and burned the town of Paita. The original design of the expedition being frustrated, he conceived the project of intercepting the Manila or Acapulco galleon, a Spanish ship laden with bullion and other valuables to a vast amount, which sailed annually between Acapulco in Mexico, and Manila, one of the Philippine islands. With this view he hovered on the west coast of America till May, 1742, when he set sail to cross the Pacific Ocean. In the course of this voyage, the Gloucester and the other vessels were destroyed for want of men to navigate them, and he proceeded with only the Centurion, and that but half manned, owing to the sickness and mortality which had thinned the crews. The hardship endured on this part of the voyage was extreme, from the shattered condition of the ship, as well as the prevalence of scorbutic disorders. The first land which the voyagers made was the uninhabited island of Tinian, one of the Ladrões, of which a most fascinating description is given. Here the commodore remained some time to refresh his crew; and his constancy and equanimity were signally shown during this period. The Centurion was driven from her moorings out to sea, leaving himself and the greater part of the sailors and officers on shore. In this emergency his calmness and spirits never failed. He gave orders immediately for the construction of a vessel, engaging personally in the most laborious employments; and the greatness of his anxiety would have remained unknown, but for his transports of joy on the unhoped return of the Centurion.

The health of the crews being in some degree recruited, Anson proceeded on his course to China; and arrived at Macao, an island and town in the bay of Canton, November 12, 1742. He remained there till the beginning of 1743, during which interval the vessel was new-sheathed, and a reinforcement of sailors procured. He now resumed his design of intercepting the Spanish galleon, and he steered his course back to the Straits of Manila. He met and took her after a short but sharp engagement, June 20. In the moment of victory, a fire broke out near the powder-room of the Centurion, the extinction of which was owing to the commodore's calm promptitude. The prize was mounted with forty guns, manned by six hundred sailors, and laden with treasure and effects to the value of 313,000*l*. He retired to China for the purpose of selling her; and thence proceeded round the Cape of Good Hope to England, and arrived at Spithead in safety, June 15, 1744. The contrast between the disasters of the earlier and the good fortune of the latter half of his voyage is remarkable, for dangers beset him to the last. On his arrival in England, he discovered that he had passed in a fog through the midst of a French fleet then cruising in the Channel. The commander himself was enriched by this expedition, and the character of Great Britain for skill and intrepid seamanship was confirmed and heightened; but in a political view, the nation was not indemnified for the expense. The object, as a general measure of warlike operations, was frustrated. The lying in wait for the Manila ship was an afterthought, had the chapter of accidents, so eventful in maritime occurrences, terminated unfavourably in spite of all his vigilance, he might have been superannuated on his return to England, and have died in obscurity. But his talents as an officer were rendered influential by his wealth: he was heard as an oracle in all naval deliberations, and rose by uninterrupted gradations to the highest honours of his profession, and also to the peerage.

Soon after his return, Anson was appointed Rear Admiral

of the Blue, and one of the Lords of the Admiralty. In April, 1745, he was made Rear-admiral of the White, and in July, 1746, Vice-admiral of the Blue. He was also elected parliamentary representative of the borough of Heydon, in Yorkshire. During the winter of that year, he commanded the Channel squadron in a long and tempestuous cruise. In the following spring, May 3, being in command of a powerful fleet of fourteen ships, besides a sloop, and fireship, he fell in with two combined French fleets, bound to the East and West Indies, laden with merchandise, treasures, and warlike stores, protected by a strong convoy. On this occasion he captured six ships of war, not one escaping, together with four armed East Indiamen. M. de St. George, captain of the *Invincible*, on presenting his sword to the conqueror, said, in allusion to the names of two of the captured ships, in the characteristic epigrammatic style of French compliment, 'Sir, you have conquered the *Invincible*, and carry Glory in your train.'

For his signal services, King George II. rewarded Admiral Anson with a peerage, by the title of Lord Anson, Baron of Soberton, in Hants. In the same year he was appointed Vice-admiral of the Red; and on the death of Sir John Norris, Vice-admiral of England, an appointment rather of a civil than a naval character, but always given to a naval man. In 1748, he was appointed Admiral of the Blue, and commanded the squadron which conveyed George II. to and from Holland. He ever after attended the king in his voyages to the Continent. In 1751, he was appointed First Lord of the Admiralty, in which station he continued, with a very short interval, till his death. The occasion of his temporary retirement was the unpopularity incurred by the government in consequence of the untoward events of which Admiral Byng was the victim; but those events belong more properly to the political history of the period than to the personal transactions of Lord Anson's life.

In 1758, being then Admiral of the White, he hoisted his flag on board the *Royal George*, 100 guns, and sailed from Spithead on the 1st of June. Sir Edward Hawke commanded under him. By cruising continually before Brest, he covered the descent which was made that summer at St. Maloes and Cherbourg. On the accession of George III., he was appointed Admiral and Commander-in-chief of his Majesty's fleets. He died suddenly, June 6, 1762, aged 65, at his seat at Moor Park, in Hertfordshire, having for some time been in a shattered state of health. He married the eldest daughter of Lord Chancellor Hardwicke, who died before him without issue.

His professional characteristics were those of discretion, coolness, and steadiness. In contemplating the risk of his own ship being lost in doubling Cape Horn, he gave such directions to the other commanders as were calculated to secure the success of the voyage. At Juan Fernandez he set the example, and compelled his officers to assist, in carrying the sick sailors, in their hammocks, ashore. He sowed garden seeds, and planted fruit trees in that island, for the benefit of future voyagers. He was a strict disciplinarian, and his methods were attended with such success, that at the taking of Païta, only one of his men so far neglected his duty as to get drunk. When dissensions arose concerning the distribution of the plunder seized there, he showed his generosity by throwing up his own share to augment the portions of his officers and men. His humanity was eminently displayed in his kind treatment of his prisoners; by which he won the admiration and respect of the American Spaniards, and did much to remove the opinion of the excessive cruelty of the English, arising out of the atrocities committed in past times by the buccaneers. He directed his attention to the improvements of geography and navigation, by making careful surveys of the coasts which he visited. It has been said that he was addicted to gambling, and a dupe to sharpers. The charge is contradicted by Dr. Kippis in the *Biographia Britannica*; but the apologist contents himself with stating that 'upon the whole he neither won nor lost by gaming; and he made it, like hundreds of others who pass uncensured, his amusement rather than his business.' A witty remark that 'he had been round the world, but never in it,' was probably, like many similar sayings, hazarded for the sake of the point rather than for its strict applicability. *Lord Anson's Voyage round the World* went through four large impressions the first year, and has been translated into most Euro-

pean languages. It was written by Mr. Benjamin Robins, from materials furnished by Lord Anson, and digested under his own inspection. A journal of Anson's voyage was published in 1745, by Pascoe Thomas, teacher of the mathematics on board the *Centurion*.

ANSTEY, CHRISTOPHER, a poet of the last century, born October 31, 1724, now little known except as the author of the *Bath Guide*. He received the rudiments of his education at the free school of Bury St. Edmunds, whence he was removed to Eton; and in due time succeeded to a fellowship at King's College, Cambridge. He took his bachelor's degree in 1746, but was prevented from proceeding at the regular time to the degree of M.A., by a whimsical quarrel with the University authorities. In consequence of this, he was refused his master's degree, in 1749; but he continued to hold his fellowship, and occasionally resided at college.

On his mother's death, in 1754, he succeeded to the estates of his maternal grandfather, at Trumpington, near Cambridge, and resigned his fellowship. In the year 1766 he published his *Bath Guide*, a satire on the follies of fashionable life, especially as developed at that gay watering-place. This is one of the lightest, wittiest, and most amusing satires of the kind in the English language, and obtained great popularity; inasmuch, that Dodsley the bookseller, who had purchased the copyright for 200*l.*, after two editions had been published, returned it to the author in 1777, stating that he had made more by it than he ever had made by any book in the same length of time. It should be mentioned to Mr. Anstey's honour, that he presented the profits of the work to the General Hospital of Bath. The merits of the work are tarnished by a broadness of humour, and an occasional irreverence in speaking of things connected with religion, which, though aimed at hypocrisy, and not intended to bring true religion into contempt, would scarcely be tolerated in the present day. The manners and follies which this lively *jeu d'esprit* was written to commemorate, have passed away; and from the combined effect of these two causes, it is probable that the *Bath Guide* will be little known to the rising generation.

Mr. Anstey wrote several poetical pieces of no great length, which are collected in one volume quarto, with a memoir of his life prefixed by his son. The most remarkable of them is the *Election Ball*, written much in the same strain as the *Bath Guide*. This he translated into Latin verse; as well as a selection from Gay's *Fables*, Gray's *Elegy*, and some other pieces. He was fond of this exercise, and versified with elegance and correctness. He spent the latter years of his life at Bath, and died there in 1805.

ANSTRUTHER EASTER AND WESTER, two royal burghs in Fifeshire, Scotland; situated on the sea-coast facing the S.E., and on each side of the mouth of a small rivulet, about 35 miles N.E. by N. of Edinburgh. Anstruther Easter is considerably the larger place of the two, having a population (in 1831) of 1007 persons; Anstruther Wester has only 430. Till the year 1636 Anstruther Easter was in the parish of Kilrennie, but was then erected into a separate charge and the church built. It is in the Presbytery of St. Andrew's and the Synod of Fife: Sir John Anstruther is the patron. In 1710 it was made a port, and the custom-house established; and, in 1753, a new quay was erected. The town lies low, and the only good street is that which runs along the quay. Ship-building, tanning, and fishing, are the chief occupations of the inhabitants. There is a post-office. Lat. 56° 14' N., long. 2° 44' W. of Greenwich.

Anstruther Wester was made a royal burgh in 1583, having been previously a burgh of Barony. The parish church is a very ancient structure. The inhabitants were zealous covenanters in the time of Charles I., and suffered severe loss in the battle of Kilsyth against the Marquis of Montrose in 1645. The author of the account of this parish in Sir John Sinclair's *Statistical Account of Scotland*, remarks with great naïveté, 'Since the battle of Kilsyth the people here have a strong aversion to a military life.' The town was further injured to a great extent by two inundations of the sea, one in 1670, which destroyed or choked up the harbour, and another towards the end of the same century, which destroyed about one-third of the town. The rock on which the town-house once stood is covered by the sea every spring-tide. The trade of this and other towns on this part of the coast is thought to have suffered from the union with England. The harbour does not admit ships of burden; but a little to the westward

is a creek, called Westhaven, much used in the fishing season, which might easily be made a good harbour.

The creek between Easter and Wester Anstruther is said to have been the seat of a considerable salmon fishery. A variety of fish is still caught and sent to Edinburgh, Glasgow, and other places: lobsters are sent to London. Several vessels belong to these towns; and some coarse linens are made in the different families. The Anstruthers are included in the St. Andrews' district of burghs, which district returns one member to parliament.

Opposite to the Anstruthers is the Isle of May, a mile long and three-quarters of a mile broad, which is considered an excellent place for improving the fleeces of sheep kept there, though only for one season: there is a lighthouse on it.

ANT (*Formica*), a well-known genus of insects, which has attracted attention from the earliest ages, on account of the singular economy and extraordinary industry manifested by the different species. In various parts of the three volumes on insects in the *Library of Entertaining Knowledge*, numerous minute details are given of the interesting proceedings of ants; but at present we shall confine ourselves to a more brief but more methodical outline of their natural history. In tracing the history of most insects, it is best, perhaps, to begin with the eggs; but in the case of the ant, the laying and hatching of the eggs could not be well understood without an acquaintance with their singular manner of pairing, with which, therefore, we shall begin.

Pairing of Ants.—It may be necessary to premise here, that, similar to bees, a community of ants, whatever the species may be, consists of males, which have always four wings; of females, much larger in size than the males, which only possess wings during the pairing season; and of a sort of barren females, which have been variously termed neuters, workers, or nurse-ants, and which, so far as we know, have never been observed to have wings in any stage of their existence.

If an ant-hill be examined any time after midsummer up to the close of autumn, there may be seen, mixed with the wingless workers, a number of both males and females furnished with white glistening wings. These, however, are neither kings nor queens in the state, at least so far as freedom of action is concerned, for they are not allowed to move without a guard of workers to prevent their leaving the boundaries, and if one straggles away unawares, it is for the most part dragged back by the vigilant sentinels, three or four of whom may, in such cases, be seen hauling along a single deserter by the wings and limbs. The workers, so far from ever facilitating the exit, much less the departure, of the winged ones, more particularly the females, guard them most assiduously in order to prevent it; and are only forced to acquiesce in it when the winged ones become too numerous either to be guarded or fed. There seems, indeed, to be a uniform disposition in the winged ones to desert their native colony; and as they never return after pairing, it would soon become depopulated in the absence of females. The actual pairing does not seem to take place within the ant-hill, and we have observed scouts posted all around, ready to discover and carry back to the colony as many fertile females as they could meet with. Nay, we are quite certain that whole colonies have been thus dispersed; and when they did not find fertile females near their encampment, they have gone farther and farther till they found them, and, if they had gone very far, never returned, but commenced a number of new establishments, according to their convenience. It is probable that, soon after pairing, the males die, as do the males of bees and other insects; for, as the workers never bring any of them back, nor take any notice of them after leaving the ant-hill, they must perish, being entirely defenceless, and destitute both of a sting and of mandibles to provide for their subsistence. The subsequent proceedings of the females are very different, and of curious interest. It was supposed by the antients that all ants, at a certain age, acquired wings; but it was reserved for the younger Huber, in particular, by means of his artificial fornicaries, to trace the development of the wings in the female from the first commencement, till he saw them stripped off and laid aside like cast clothes.

This curious process, which was first hinted at by Gould in his interesting account of *English Ants*, we have repeatedly witnessed,—the females extending their wings, bringing them over their heads, crossing them in every direction, and throwing them from side to side, till at length they are disjointed from the body and fall off. Those, however, who

are desirous of verifying the observation, must procure winged females immediately after pairing, and place them under a glass with some moist earth.

Foundation of Colonies.—Some of the females are, after pairing, usually captured by the working ants, and conducted back to the parent community; and others are laid hold of by straggling parties of from two to a dozen workers, who do not return to the parent community, but commence small colonies on their own account. This explains the common occurrence of a great number of small colonies being formed in the immediate vicinity of each other, while sometimes the parent community is thereby quite broken up and the hill deserted. This happens frequently in the case of the red ant (*Myrmica rubra*) and the ash-coloured ant (*Formica fusca*), both very common species in fields and gardens. In the case of the yellow ant (*F. flava*) again, and the wood ant (*F. rufa*), this rarely occurs, the parent community often remaining in the same spot for years together.

When a female, after pairing, does not chance to fall in with any scouting parties of workers, she proceeds without their assistance to found a colony herself in the same manner as is always done by the females of the social wasps and humble bees every spring. We have repeatedly verified this fact, both by confining a single female after pairing, and witnessing her proceedings, and by discovering in the fields single females occupied in laying the foundations of a future city for their progeny. We have met with these single females when they have just begun to form the first cell for the reception of their eggs; when the eggs have just been laid; when the eggs have been hatched; and also when: few workers had been reared to assist in the common labours. To verify the latter observations, however, many hundreds of stones must be turned over in August or September in a place where ants abound; and even with all this the naturalist will probably not discover more than three or four solitary females at work in the course of a season. We have ourselves met with only ten or a dozen instances in the course of several years.

The Laying and Hatching of the Eggs.—The younger Huber says, 'Having directed my close attention to the eggs of ants, I remarked that they were of different sizes, shades, and forms. The smallest were white, opaque, and cylindrical; the largest transparent, and slightly arched at both ends; while those of a middle size were semi-transparent. On holding them up to the light, I observed a sort of white oblong cloud; in some, a transparent point might be remarked at the superior extremity; in others, a clear zone above and underneath the little cloud. The largest presented a single opaque and whitish point in their interior. There were some whose whole body was so remarkably clear as to allow of my very distinctly observing the rings. On fixing attention more closely upon the latter, I observed the egg open, and the grub appear in its place. Having compared these eggs with those just laid, I constantly found the latter of a milky whiteness, completely opaque, and smaller by one-half, so that I had no reason to doubt of the eggs of ants receiving a very considerable increase in size; that in elongating they become transparent, but do not at this time disclose the form of the grub, which is always arched.'

Contrary to what takes place in most insects, the eggs of ants are not, when laid, glued to any fixed place, but are found in parcels of half a dozen or more loosely attached, so that they can be removed at pleasure during the hatching. It has been shown in the *Penny Magazine*, (vol. i. p. 60.) by a series of minute observations, that the female earwig moves her eggs with the utmost care from a place which she judges too dry, to one which is sufficiently moist; and in the same way the female ant, when she founds a colony without assistance, or the nurse-ants in a community, change the situation of the eggs according to the state of the weather or of the day and night,—a circumstance first observed by Dr. Kütz in the reign of King Charles II. Heat being indispensable to their successful hatching, the eggs are carefully placed during the day near the surface of the ant-hill, but so sheltered from the direct influence of the sun as to prevent the too rapid evaporation of their moisture. During the night, or in cold weather, the eggs are not placed so high to prevent the radiation and escape of the heat which they naturally possess. The attention to the state of temperature occupies much of the assiduity of the female and the nurse-ants.

When the eggs are at length hatched, (and during this process, we have already seen that they enlarge in size,) the young grubs are similarly treated with respect to temperature, but greater care is now taken to preserve them from too great heat, which might prove more injurious than before hatching.

The grubs are fed by the nurse-ants when any of these are in the colony, and by the mother when she is alone, by a liquid disgorged from the stomach, as is done in a similar way by wasps, humble bees, pigeons, and canary birds. It consequently requires no little industry on the part of a solitary female to procure for herself sufficient food to supply nutriment for a brood of perhaps a dozen or twenty grubs, which are insatiably voracious.

When the grubs are full grown, they spin for themselves cocoons of a membranous texture, and of a brownish-white colour, not unlike barleycorns in appearance, and indeed mistaken for these by early observers,—a mistake which led to the unfounded notion that ants store up corn for winter provision, though, from their always becoming torpid in the winter, they could have no need of this; and even were this not so, they never feed on corn, and would probably starve rather than taste it. The authority of Scripture, which has been supposed to countenance the popular notion, is shown by the Rev. Dr. Harris, Messrs. Kirby and Spence, and others, to have no foundation in the sacred text.

The cocoons are treated precisely like the eggs and the grubs with regard to exposure to heat; and the anxiety of the nurse-ants to shelter them from the direct rays of the sun is taken advantage of on the Continent to collect the cocoons (popularly and erroneously called ants'-eggs) in quantity as food for nightingales and larks. The cocoons of the wood-ant are the only species chosen; and in most of the towns in Germany one or more individuals make a living during summer by the business. In 1832 we visited an old woman at Dottendorf, near Bonn, who had collected for fourteen years. She went to the woods in the morning, and collected in a bag the surfaces of a number of ant-hills where the cocoons were deposited, taking ants and all home to her cottage, near which she had a small tiled shed covering a circular area, hollowed out in the centre, with a trench full of water around it. After covering the hollow in the centre with leafy boughs of walnut or hazel, she strewed the contents of her bag on the level part of the area within the trench, when the nurse-ants immediately seized the cocoons and carried them into the hollow under the boughs. The cocoons were thus brought into one place, and after being from time to time removed, and black ones separated by a boy who spread them out on a table, and swept off what were bad with a strong feather, they were ready for market, being sold for about 4d. or 6d. a quart. We have seen temporary areas made for the same purpose in the woods, but for want of a confining trench of water, many cocoons were carried off by the ants. Considerable quantities of these cocoons are dried for winter food of birds, and are sold in the shops.

In the case of moths, ichneumons, and other insects which spin themselves up in cocoons, the included insect, when the time of its change arrives, is enabled to make its own way through the envelope; but though it would appear, from some observations made by Swammerdam, that ants may, when forced thereto, effect their own disengagement, this is not the usual process. It is the nurse-ants that cut a passage for them with their mandibles, as was first minutely described by Baron de Geer and the younger Huber:—'Several males and females,' says the latter, 'lay in their envelopes in one of the largest cavities of my glazed ant-hill. The labourer-ants assembled together, and appeared to be in continual motion around them. I noticed three or four mounted upon one of these cocoons, endeavouring to open it with their teeth at that extremity answering to the head of the pupa. They began to thin it by tearing away some threads of silk where they wished to pierce it, and at length, by dint of pinching and biting this tissue, so extremely difficult to break, they formed in it a vast number of apertures. To expedite the work, some raised up a little slip cut out in the length of the cocoon, whilst others drew the insect gently from its imprisonment. When the ant was extricated from its enveloping membrane, the body was still confined by another membrane, from which it could not by its own exertions disengage itself. The labourer-ants removed the satiny-like pellicle which embraced every part of the body, drew the antennæ gently from their investment, then disengaged

the feet and the wings, and lastly the body, with the abdomen and its peduncle. The insect was now in a condition to walk and receive nourishment, for which it appeared there was urgent need. The first attention, therefore, paid it by the guardians was that of giving it the food I had placed within their reach.'

Labours of the Working Ants.—We have already seen that workers or nurse-ants have to labour assiduously in placing the eggs, the grubs, and the cocoons in due degrees of temperature; that they have to feed the grubs by a liquid disgorged from the stomach, and have to disengage the insect at its period of change from the envelope of the cocoon. They have also to perform the task of forming streets, galleries, and chambers for the habitation and protection of the colony, and they exhibit in the work such perseverance and skill as must excite the admiration of every observer. Many of their processes, indeed, it is not a little difficult to account for and explain, though these have been very carefully investigated, particularly by the younger Huber, in whose work, and in *Insect Architecture*, (p. 254 *et seq.*) may be found copious details of the mining, masonry, and carpentry of various species. We shall here give an instance of each of those operations.

Mining.—There is an interesting species called the sanguinary ant (*F. sanguinaria*, Latreille), reported to have been seen near London, but which is certainly very rare, if it is found in England. In the summer of 1832 we discovered several colonies of this ant on the brow of the heath above Godesberg, on the Rhine, and being desirous of taking a number of them alive to England for the purpose of observing their singular manners, we waited till the beginning of October, when they had ceased to work, and had retired for the winter to their galleries underground. After uncovering the thick coping of dry heath twigs and grass stems which was placed over the subterranean city of the colony so as to defend it from rain and cold, we found several covert-ways dug into the clay, wide enough to allow two or three ants to walk abreast; but not an individual now made its appearance, though some weeks previous we had observed thousands in all the bustle of industry; and we began to fear the whole had migrated elsewhere. Being anxious, however, to see the interior structure, we dug in the direction of the covert-ways to the depth of about six or nine inches, when we came upon a number of chambers communicating with each other by galleries, and from an inch to two or three inches in extent, in each of which a number of ants were lying along the floor in a half torpid state, being so sluggish that they could not be brought to run with their usual agility even when irritated.

The point which we wish to call attention to here is that the whole of the apartments which we laid open, amounting to a dozen or more,—and there were probably as many more to which we did not penetrate,—must have been dug out of the solid clay by the jaws (*mandibula*) of these little miners. We deemed it singular that we could see none of the rubbish lying about, which must have been cleared away from the interior, and we can only account for this by supposing the colony long established, and the rubbish battered into the grass by the weather.

In other instances of mining, such as in the case of the turf-ant (*F. Cæspitum*), the clay taken from the interior is built up on the outside, using the herbage for buttresses to support the walls thus formed. In the case of the sanguinary ants, however, we observed nothing of this kind, and do not think they ever employ any exterior masonry.

Masonry.—The most common of our English ants which employ masonry is the yellow ant (*F. flava*), whose hills are so usually found built up in old pastures, a foot or more in height, and from six inches to two feet in diameter. For the materials of their building they are wholly indebted to the soil below, which they quarry out with great assiduity; but as they have no means of tempering the clay when it is dry, they are always forced to execute their principal works in rainy weather. 'I was,' says Dr. J. R. Johnson, 'in the habit of visiting, almost daily, for a month, an extensive nest of red ants, of which a large flat stone formed the roof. During my visits for the first three weeks, scarcely a drop of rain had fallen, and the nest seemed considerably injured by the continual falling in of loose earth, which these little creatures with amazing industry removed, whenever it happened any of the avenues were blocked up. No attempt was ever made towards reparation; but what was my surprise, on visiting my little friends after a two days' heavy

rain, to find that the repairs were already completed, and that the upper surface of their habitation presented as smooth a surface as if a trowel had been passed over it; yet all their work they had industriously effected by kneading with the rain-water the loose earth into a sort of paste. From the nest being situated in the midst of an extensive heath, where there could be no supply of water, and from its remaining unrepaired during the dry weather, it amounts to a full conviction that ants employ no other cement than water in the construction of their varied habitations.

I have often been surprised at the ingenuity of these little creatures, in availing themselves of contiguous blades of grass, stalks of corn, &c., when they wish to enlarge the boundaries of their abode. As these are usually met with in the erect position, they are admirably calculated for pillars; they, therefore, coat them over with a fine paste of earth, giving them, by additional layers, the solidity they judge necessary for the work on which they are engaged; they then leave them to be consolidated by the wind, and afterwards spring a number of arches, from pillar to pillar, and thus form an extensive saloon. Should they be, at any time, in want of small apartments, they have only to prepare a quantity of moistened earth, and by placing this between the pillars, and carrying it up to the roof, leaving here and there an aperture for entrance, their object is completely attained.

It is remarkable that the greater part of these masonic labours are performed during the night, or at least in gloomy weather.

Carpentry.—The coping which we have already described as placed over the subterranean abode of the sanguinary ants, and which is still more remarkable in the colonies of the wood-ant (*F. rufa*), cannot be referred to any sort of carpentry, for the small sticks and straws of which it is composed are not cut into fitting lengths, but collected in the vicinity of the hill and laid on it after the manner of thatch. The term carpentry, however, will apply most justly to those species which form excavations in the interior of trees, of which the following is an instance observed in 1832.

We had brought into our garden in the beginning of June, a large piece of a willow tree, which had been very curiously worked out by the species usually called the emmet (*F. fuliginosa*, Latreille). The tree, indeed, from which it had been taken, appeared to have been destroyed in a great measure from the extensive excavations of these little carpenters. Yet the portion of the tree alluded to seemed to be singularly strong, when the great number of the cells and their peculiar structure was taken into consideration. The walls of these cells were literally as thin as writing-paper, though not quite so smooth and even, and they were seldom quite parallel, but arranged, some perpendicularly, and others slanting in various directions, worked out, it would appear, upon no previous design, but beginning at any given point, and only limited in extent by the worker discovering his approach to one adjacent. The tact with which they chisel away the wood with their jaws, so as to come so near the next cell without actually cutting into it, cannot well be accounted for on any of the common principles of human mechanism. It cannot be the result of vision, from the worker-out looking along the level of the plane, as one of our carpenters would do, and thence working so as not to cut through it; for the wall has, in most instances, though not in all, no free edge along which such a level could be taken by the eye. Hearing might assist them, however, supposing workers to be engaged in chiselling on each side of the partition, but it would appear to be more from touch, or rather that modification of it denominated tact, which enables them to feel, as it were, when they have nearly penetrated the wall, and which consequently warns them to stop.

It is not a little remarkable, that all the wood which is worked out by these ants is tinged of a black colour, giving all their streets and lanes somewhat the appearance of having suffered from fire or of being smoked. M. Huber the younger did not succeed in ascertaining the cause of this black colour. We should conjecture it to arise from iron contained in the saliva of the ants acting on the gallic acid of the wood, in a similar way as the same wood becomes black when cut with a knife. The fine glossy black of the ants themselves may originate from the same chemical principle, and this is rendered more probable from the excavations made by other species, such as the dusky ant, (*F. fusca*, Latreille,) not being tinged with this black colour.

Neither are the excavations of the latter so regular in the form of the cells; and the delicately thin partitions do not occur. We have seen several colonies of the yellow ant (*F. flava*, Latreille) established in trees, though their usual habits lead them to prefer a hedge-bank, the dry ridge of a field, or a small knoll on a common. In none of these, however, had the workers much trouble in making their excavations, the trees being in every instance far gone with the dry rot, and the chambers were consequently as easy to construct as in a knoll of sand. In the instance of the black carpenter-ant (*F. fuliginosa*), on the other hand, the wood of the tree selected for their colony is always hard and tough, the easiness of working it being apparently considered a disadvantage rather than a recommendation. We have usually seen these colonies, therefore, in growing trees, the oak seeming to be preferred to all others; the honeycomb-like work does not seem to stop the vegetation, the tree continuing to put forth leaves and shoots as before it was excavated for the use of the colony. In the instance which gives rise to these remarks, the willow tree was indeed dilapidated and shorn of its leaves and branches, yet was it untouched with dry rot, and the wood was hard and tough.

Food of Ants.—Some species of ants are carnivorous and will eat insects, fruits, and almost anything eaten by other animals, but honey is the most universal favourite among all the species, particularly the excretion of the various species of aphides called honey-dew. It is on this account that, wherever aphides abound, we are always certain to meet with ants carefully attending their motions and greedily drinking the honey-dew, which becomes so injurious to plants when it increases in quantity so as to obstruct the pores of the leaves. It is stated by Huber and some other authors, that during winter the ants imprison some aphides in their cells, or, at all events, take advantage of individuals of the grass aphid (*Aphis Graminum*) in the vicinity of their hills to obtain honey-dew. We strongly suspect there must be some fallacy in this statement; for among numerous colonies which we have carefully examined during winter, we always found the whole population torpid or nearly so, and not inclined to touch even honey when we offered it to them. In the case of the sanguinary ants in Germany already mentioned, we have seen that they had become torpid as early as October, when the weather was still fine and far from being cold. We are therefore of opinion that the statement will be found as void of accurate foundation as that which represents ants as storing up corn for the winter.

Migrations.—We have already seen, under the head of pairing, one principle in operation for spreading around a parent ant-hill a number of young colonies. This indeed may be considered the main principle of migration; but besides this, the whole of a populous ant-hill which has been established for several years will, for some cause beyond our means of tracing, though most probably on account of more convenient forage, at once desert their homes and march to a new station. Among the yellow ants, the emmets, and the wood-ants or pismires, this is by no means common; but it is an every-day occurrence among the red ants, the ash-coloured ants, the turf ants, and others whose colonies never become very populous, and are consequently both more easily moved and more easily provided with lodging.

'Immense swarms of ants,' to use the words of Dr. Roget, 'are occasionally met with, and some have been recorded of such prodigious density and magnitude as to darken the air like a thick cloud, and to cover the ground to a considerable extent where they settled. Mr. Gleditsch describes, in the *History of the Berlin Academy* for 1749, shoals of a small black ant which appeared in Germany, and formed high columns in the air, rising to a vast height, and agitated with a curious intestine motion, somewhat resembling the aurora borealis. A similar flight of ants is spoken of by Mr. Accultre, a clergyman of Breslau, which resembled columns of smoke, and which fell on the churches and the tops of the houses, where the ants could be gathered by handfuls. In the German *Ephemerides*, Dr. Charles Rayger gives an account of a large swarm which crossed over the town of Posen, and was directing its course towards the Danube. The whole town was strewn with ants, so that it was impossible to walk without trampling on thirty or forty at every step. And more recently, Mr. Dorthes, in the *Journal de Physique* for 1790, relates the appearance of a similar phenomenon at Montpellier. The shoals moved about in

different directions, having a singular intestine motion in each column, and also a general motion of rotation. About sunset all fell to the ground, and, on examining the ants, they were found to belong to the *Formica nigra* of Linnæus.

Wars and Expeditions to capture Slaves.—In the same way as the bees and the wasps of different hives manifest inveterate hostility when they meet, ants also of the same or of different species assail one another when they meet during their foraging excursions. Besides the individual skirmishes which thence occasionally arise, pitched battles are sometimes fought between the whole or nearly the whole force of populous adjacent colonies. We have never ourselves witnessed any very extensive battles of this kind, such as Huber describes, in which thousands of combatants were engaged, but we have seen as many as fifty of the wood-ants fighting most pertinaciously within the area of a few inches on what were supposed to be the boundaries of their several territories; their bite is so sharp, and the acrid acid which they infuse is so deleterious, that many are thus disabled or killed outright. Huber witnessed on such occasions very extensive carnage.

Besides these skirmishes and battles which occur among all the species, there are whole communities of warrior-ants, as was first discovered by Huber, whose history is so extraordinary as almost to exceed belief. The details indeed have hitherto been credited chiefly, if not solely, on the well-known veracity of Huber; but in the autumn of 1832 we had an opportunity of verifying them both in the Black Forest and in Switzerland, with respect to the species which he terms the Amazon ant, (*F. rufescens*, Latreille,) and on the Rhine with respect to the sanguinary ant.

Both of these species make war on the ants of a different species from themselves, particularly the dusky ant, (*F. fusca*), not for the purpose merely of gratifying a propensity to combat, but to make slaves of the vanquished to do the drudgery of the conquerors at home. The manner in which they proceed in this affair manifests, so far as we can judge, deep design, such as might be ascribed to the counsels of a cunning diplomatist. They do not capture the adult ants and carry them into slavery, but make booty of the eggs and cocoons, which, after the contest is decided,—and the warriors are always conquerors,—are carried off to the Amazonian citadel, and being hatched there, the poor slaves are most probably not aware but that it is their native colony. Huber repeatedly witnessed such expeditions for the purpose of capturing slaves; but though we were not so fortunate, we witnessed, in a great number of instances, the slaves at work for their warlike captors.

The Amazons have not hitherto been found in Britain, and we were unsuccessful in our attempt to bring over from the Black Forest a nest of live ones with their slaves which we had placed in a box for the purpose. We succeeded indeed in bringing safe home two nests of the sanguinary ants already alluded to under *Mining*, together with a number of their slaves, but they all died within two months, having been kept, as we suppose, too warm for their state of winter torpidity, already begun, and they could not, in their half-awakened state, be induced to take any sort of nourishment.

ANT-BEAR, the name commonly given to the *Myrmecophaga jubata* by the English at Demerara. (See next article.)

ANT-EATER, (*Myrmecophaga*, Linnæus,) in zoology, a genus of *Edentata*, distinguished by their total want of teeth and hairy covering. The latter circumstance separates them from the *pangolins* (*Manis*), or scaly ant-eaters of Africa and Asia, which they resemble closely in other respects, as well in their general anatomy as in their food and habits. These two genera form a small but very distinct family of the Cuvierian order *Edentata*, differing from the common animals comprised in that singular group, as well as from all other known mammalia, by their entire deprivation of the organs of mastication, and acquiring an additional interest by the light which their osteological conformation throws upon the structure and organization of the *megatherium* and *megalonix*, those extraordinary antediluvian animals, whose fossil remains have lately attracted so much of the attention, not only of the professed naturalist, but likewise of the public at large. The relations which these extinct inhabitants of a former world bear to another small family of edentatous mammalia have been already pointed out in the article *A1*, and their general organization and affinities will be formally treated under the proper heads, at a future period. We shall therefore merely observe at present, that as the osteo-

logy of their skulls and trunks presents the closest analogies with that of the corresponding parts in the sloths, so the whole construction of their extremities appears to have been formed after the same model as that of the corresponding organs of the ant-eaters. The head of these latter animals, indeed, is altogether different from that of the sloths; not only does it want the organs of mastication, of which they are deficient only in the incisors, but the bones of the face, which in them are short and round like those of apes and monkeys, are prolonged in the ant-eaters, particularly in the great ant-eater, (*M. jubata*), to double the length of the skull. This singular conformation arises from the form of the maxillary or jaw bones, and those of the nose, which form together a kind of long tube, very small in proportion to its length, and almost cylindrical. This prolongation of the muzzle is not carried to so great an extent in either of the other two known species of ant-eaters; but even there the construction here described differs only in degree, and presents, on a more contracted scale, all the characteristics of the *myrmecophaga jubata*.

It is in the construction of the anterior extremities, however, that these animals offer the greatest singularities, and become most important in their relations to the fossil species. The phalanges or joints of the toes, particularly the last, which bear the claws, are formed in such a manner as to permit them to be bent inwards only, as in the sloths; and for this purpose they are provided with very powerful ligaments, which keep them, in a state of repose, bent in along the sole of the foot, and never permit the hand to be completely opened, but only half extended, as we sometimes see in gouty or rheumatic people. The toes themselves are of very unequal size, and even differ in number in different species. The great ant-bear and tamandua have four on the anterior and five on the posterior extremities, whilst the smallest species, called, from that circumstance, *M. didactyla*, has only two on the fore feet and four on the hind. The toes themselves, as in the sloths, are united closely together as far as the claws, and are consequently incapable of any separate or individual motion; but the disadvantages arising from this circumstance are more than counterbalanced by the increased strength which it produces, and the consequent adaptation of the organ to the peculiar purposes of these animals' economy. The claws are all large and powerful, especially that of the middle toe, of which the dimensions are quite enormous. Nor do the ant-eaters, in walking, tread flatly upon the sole of the foot like the generality of mammalia; on the contrary, they rest entirely upon its outer edge, which is provided with a large callous pad for that purpose, whilst their toes being bent inwards along the palms, the sharp points of their powerful claws are preserved from being injured by the friction of the hard ground. In other respects the ant-eaters are remarkable for their long cylindrical tongues, covered with a glutinous saliva, by means of which they entrap and devour the insects upon which they live, and from which they derive their names, both among naturalists and common observers, *myrmecophaga* literally signifying ant-eater. This tongue is protractile, and capable of being extended to a surprising distance beyond the snout; it is nearly twice the length of the whole head and muzzle together, and when not extended is kept doubled up in the mouth with the point directed backwards. The eyes are particularly small, the ears short and round, the legs robust and amazingly powerful, but so unfavourably formed for locomotion, that the pace of these animals is almost as tardy as that of the sloths themselves, their greatest exertions not enabling them to surpass the ordinary walk of a man. The tail is always long; in the great species lax and thickly covered with very long flowing hair, in the other two, strongly prehensile and naked underneath. These species consequently climb trees and reside principally among their branches, feeding upon the wild bees and termites which inhabit the same situations: the great ant-bear, on the contrary, never quits the surface of the earth, and confines his depredations entirely to the numerous species of large ants which inhabit his native regions, and furnish him at all times with an abundant and easily procured nutriment. The whole genus is confined to South America, and contains at present only three distinct and well-defined species.

1. The *Great Ant-bear*, (*M. jubata*, Lin.) called *gnou roumi* or *yوقي* by the Guaranis, *tamandua* by the Portuguese, *tamanoir* by the French of Cayenne, and *ant-bear* by the English and Spaniards, is a large animal which mea-

asures, when full grown, four feet and a half from the extremity of the snout to the origin of the tail. The tail itself is three feet three inches in length, reckoning to the extremity of the hair, or measured only along the stump, two feet four inches; the head, thirteen inches and a half from the snout to the base of the ear, and ten inches and a half to the anterior angle of the eye; its circumference immediately before the eyes, where it is the thickest, is fourteen inches, but from this part it gradually diminishes to the end of the muzzle, where it measures only five inches and a quarter. The height of the animal at the shoulder is three feet three inches, and at the croup only two feet ten, because, being

[Great Ant-eater, *M. jubata*.]

perfectly plantigrade, it necessarily stands lower on the hind legs than before, as may be observed in the common bear, the badger, and other species which partake of the plantigrade formation of the extremities. The ear is short and round, being an inch and a quarter broad at the base, and only an inch in length; the eye is remarkably small, deeply sunk in the head, and with a naked eyelid; the head and snout, as already observed, are prolonged to a remarkable degree; they are in form almost cylindrical, and end in a small truncated muzzle, having the nostrils and mouth placed at its extreme end: the latter is so small that its whole width scarcely exceeds an inch, and the jaws are of equal length. The tongue is almost cylindrical, fleshy, extremely flexible, and capable of being protruded to the distance of sixteen or eighteen inches. The toes of the anterior extremities, four in number, are of unequal length, the innermost being the smallest and weakest of all; the second measures two inches and a half in length, and is provided with a powerful crooked claw nearly two inches long, sharp pointed, and trenchant on its under surface; the third, which is the largest of all, has a similar claw two inches and a half in length; and the fourth, or exterior toe, is provided with a smaller and weaker claw, like that of the innermost. All these claws, when in a state of repose, are kept bent inwards, and only extended, or rather half-extended, (for the animal cannot open the fingers farther,) when used for defence, or for breaking through the hard external crust of the ant-hills. For these purposes, however, its otherwise awkward conformation gives it an aptitude altogether peculiar, and such is the known power of the ant-bear, that nothing upon which he has an opportunity of fastening has any chance of escaping from the tenacity of his hold, as even in death, the structure of his legs and claws prevents them from being unclosed. The slowness of his motions, however, gives him but little chance against the activity of his most formidable enemies. Notwithstanding the exaggerated accounts which Buffon has recorded of the ant-bear successfully opposing the attacks even of the jaguar, we are assured by don Felix d'Azara, that he has not the slightest chance against this powerful animal, and that a very slight blow on the snout is sufficient to despatch him. The hind feet have five toes of nearly equal length, and all armed with short weak claws, quite useless as instruments of defence, and more resembling the claws of ordinary quadrupeds.

The toes both before and behind are covered with one common integument, and are only distinguishable by their separate claws. The hair, over the whole body, is coarse, hard, and dry, resembling in texture the bristles of the wild boar, but in some parts flattened, and assuming the appearance of long, withered grass. That of the head is short and close, but, over all the rest of the animal, it is long and shaggy, particularly on the top of the neck and along the back, where it forms a kind of long mane, and on the tail, where it is a foot in length, and hangs down on each side, sweeping the ground when the ant-bear walks.

The prevailing colour on the head, face, and cheeks of the ant-bear is a mixture of grey and brown; that on the upper parts of the body and tail is deep brown, mixed with silvery white. A broad black band, bordered on each side with a similar one of a white or light greyish-brown colour, commences on the chest, and passes obliquely over each shoulder, diminishing gradually as it approaches the loins, where it ends in a point. The sides, arms, and thighs are silvery grey, with a slight mixture of brown, marked with two deep black spots, one on the carpus, and the other on the toes: the hind legs are almost perfectly black, and the breast and belly of a deep brown, almost equally obscure.

The habits of the great ant-bear are slothful and solitary: the greater part of his life is consumed in sleeping, notwithstanding which, he is never fat, and rarely even in good condition. When about to sleep, he lies upon one side, conceals his long snout in the fur of the breast, locks the hind and fore claws into one another, so as to cover the head and belly, and turns his long bushy tail over the whole body in such a manner as to protect it from the too powerful rays of the sun. The female bears but a single young one at a birth, which attaches itself to her back, and is carried about with her wherever she goes, rarely quitting her, even for a year after it has acquired sufficient strength to walk and provide for itself. This unprolific constitution, and the tardy growth of the young, account for the comparative rarity of these animals, which are said to be seldom seen, even in their native regions. The female has only two mammae, situated on the breast, like those of apes, monkeys, and bats.

In its natural state the ant bear lives exclusively upon ants, to procure which it opens their hills with its powerful crooked claws, and at the moment that the insects, according to their nature, flock from all quarters to defend their dwellings, draws over them his long flexible tongue, covered with glutinous saliva, to which they consequently adhere: and so quickly does he repeat this operation, that we are assured he will thus exert his tongue and draw it in again covered with insects, twice in a second. He never actually introduces it into the holes or breaches which he makes in the hills themselves, but only draws it lightly over the swarms of insects which issue forth, alarmed by his attack. 'It seems almost incredible,' says Azara, 'that so robust and powerful an animal can procure sufficient sustenance from ants alone; but this circumstance has nothing strange in it for those who are acquainted with the tropical parts of America, and who have seen the enormous multitudes of these insects, which swarm in all parts of the country to that degree, that their hills often almost touch one another for miles together.' The same author informs us, that domestic ant-bears were occasionally kept by different persons in Paraguay, and that they had even been sent alive to Spain, being fed upon bread and milk, mixed with morsels of flesh minced very small. Like all animals which live upon insects, they are capable of sustaining a total deprivation of nourishment for an almost incredible time.

The great ant-bear is found in all the warm and tropical parts of South America, from Colombia to Paraguay, and from the shores of the Atlantic to the foot of the Andes. His favourite resorts are the low swampy savannah, along the banks of rivers and stagnant ponds, also frequenting the humid forests, but never climbing trees, as falsely reported by Buffon, on the authority of La Borde. His pace is slow, heavy, and vacillating; his head is carried low, as if he smelled the ground at every step, whilst his long shaggy tail, drooping behind him, sweeps the ground on either side, and readily indicates his path to the hunter; though, when hard pressed, he increases his pace to a kind of slow gallop, yet his greatest velocity never half equals the ordinary running of a man. So great is his stupidity, that those who encounter him in the woods or plains may drive him before them by merely pushing him with a stick, so long at least

as he is not compelled to proceed beyond a moderate gallop; but if pressed too hard, or urged to extremity, he turns obstinate, sits up on his hind quarters like a bear, and defends himself with his powerful claws. Like that animal, his usual, and indeed only, mode of assault is by seizing his adversary with his fore-paws, wrapping his arms round him, and endeavouring, by this means, to squeeze him to death. His great strength and powerful muscles would easily enable him to accomplish his purpose in this respect, even against the largest animals of his native forests, were it but guided by ordinary intelligence, or accompanied with a common degree of activity. But in these qualities there are few animals, indeed, which do not greatly surpass the ant-bear; so that the different stories handed down by writers on natural history from one to another, and copied, without question, into the histories and descriptions of this animal, may be regarded as pure fictions. For this statement we have the express authority of Don Felix d'Azara, an excellent observer and credible writer, from whose Natural History of the Quadrupeds of Paraguay we have derived the greater portion of the preceding account of the habits and economy of this extraordinary animal. 'It is supposed,' says Don Felix, 'that the jaguar himself dares not attack the ant-bear, and that if, pressed by hunger, or under some other strong excitement, he does so, the ant-bear embraces and hugs him so tightly, as very soon to deprive him of life, not even relaxing his hold for hours after life has been extinguished in his assailant. It is very certain that such is the manner in which the ant-eater defends himself; but it is not to be believed that his utmost efforts could prevail against the jaguar, which, by a single bite or blow of his paw, could kill the ant-eater before he was prepared for resistance; for even in so extreme a case, his motions are so slow and so heavy, that he takes some time to get himself ready, and besides being unable to leap, or turn with even ordinary rapidity, he is necessarily forced to act solely upon the defensive.' The flesh of the ant-eater is esteemed a delicacy by the Indians and negro slaves, and, though black, and of a strong musky flavour, is sometimes even met with at the tables of Europeans.

Tamandua, *M. tamandua*.

2. The *Tamandua*, (*M. tamandua*, Cuvier,) or second species of ant-eater, is an animal much inferior to the great ant-bear in point of size, being scarcely so large as a good-sized cat, whilst the other exceeds the largest greyhound in length, though, from the shortness of its legs, it is much inferior in height. The head of the tamandua is not so disproportionately long and small as that of the great ant-bear. It is, however, of the same general cylindrical form, and equally truncated at the extremity, having the nostrils and mouth situated in the same position, and equally minute, when compared with the size of the animal. Its whole length, from the extremity of the muzzle to the root of the ear, is five inches, and to the anterior angle of the eye, three inches; the body, from the muzzle to the origin of the tail, measures two feet two inches, the tail itself being one foot four inches and a half more; the height at the shoulder is one foot three, and at the croup an inch lower; the length of the ear is an inch and a quarter, its greatest breadth an inch, and the greatest circumference of the head, that, namely, taken immediately in front of the ears, eight inches and a quarter. The conformation of the extremities, and the number of the toes both before and behind, is in every respect the same as in the great ant-eater already described;

but the tamandua differs from this animal particularly in the prehensile power of its tail, which makes it essentially an arboreal quadruped, and altogether changes the most striking traits of its habits and economy. The hair over the entire body, also, is of a very different texture; instead of being long, harsh, and shaggy, as in the great ant-bear, it is short, shining, and of a consistence something between the qualities of silk and wool; standing out from the body like the latter, and of the same uniform length in every part. The colours of this species, however, are by no means so uniform and invariable as those of the species already described; on the contrary, they differ more in the tamandua, according to the individual, than perhaps in any other known animal in a state of nature. Accordingly many eminent naturalists are disposed to consider them as forming distinct species, rather than mere varieties of the same; and it is not improbable that, when we come to be better acquainted with this animal in its native woods, their opinion may be, at least partly, confirmed.

The eyes of the tamandua are minute, the ears small and round, the body long and cylindrical, the legs short and robust, the tail round and attenuated, covered with very short hair throughout its greater part, but naked underneath towards the point, and strongly prehensile. The following are the principal varieties, as regards the colours:—

1. The *straw-coloured Tamandua*, of a uniform straw-colour over the whole body, with a transverse triangular band passing obliquely over each shoulder, and encountering that from the opposite side, on the median line of the back. This band is only apparent in particular lights, and is not produced by any difference of colour, but merely by a difference of shade, arising from the hair having an opposite inclination, or direction, from that on the rest of the body.

2. The second variety is, like the former, of a uniform straw colour, but has a good deal of black about and particularly in front of the eye. This variety is found in Paraguay, and is described by Azara, who suspects its colours, as well as those of the preceding, to arise from immaturity of age, an opinion which seems to be well founded.

3. The third variety is of a silvery-white colour, with a dirty brown band running transversely over each shoulder.

4. The fourth variety is of the same silvery-white as the last, with similar dirty brown bands on the shoulders, and, besides, the croup, flanks, and belly of the same obscure colour.

5. The fifth is of a uniform clear brown, over all parts of the body, without any appearance of bands on the shoulders, or mixture of any other colour; and

6. The sixth and last variety is entirely black, with a little light brown under the tail. This variety is described by Azara, who found it in Paraguay, and who reports that it has proportionally shorter hair and larger claws than the other varieties.

The tamandua is an inhabitant of the thick primeval forests of tropical America; it is never found on the ground, but resides exclusively in trees, where it lives upon termites, honey, and even, according to the report of Azara, bees, which in those countries form their hives among the loftiest branches of the forest, and, having no sting, are more readily despoiled of their honey than their congeners of our own climate. When about to sleep, it hides its muzzle in the fur of its breast, falls on its belly, letting its fore-feet hang down on each side, and wrapping the whole tightly round with its tail. The female, as in the case of the great ant-eater, has but two pectoral mammae, and produces but a single cub at a birth, which she carries about with her, on her shoulders, for the first three or four months. The young are at first exceedingly deformed and ugly, and of a uniform straw-colour.

This animal is called *cagouaré* by the Guaranis, on account of the noxious and infected vapours of the forests in which alone it is found, the word literally signifying, in the language of these Indians, the inhabitant of a stinking wood or marsh. Such at least is Azara's interpretation of the term, though it appears more probable that it may refer to the strong disagreeable odour of the animal itself, which, this very author informs us, is so powerful that it may be perceived at a very great distance, particularly when the animal is irritated. *Tamandua* is the name by which it is known to the Portuguese of Brazil; the French and English call it *fourmillier* and little ant-bear.

It is difficult to imagine how M. de Buffon could have

been so far led astray as to mistake the stuffed skin of a *coati-mondi* for this animal, particularly after the severe though just criticism which he passes upon Leba for a similar mistake. A single glance at the plate of Buffon (*Hist. Nat., Supple. tom. iii. tab. 56*) is sufficient to convince any person who ever saw a *coati*, or who has any idea of the animal, of the real genus to which it belongs. Both Azara and Baron Cuvier long since exposed this error; yet, strange to say, notwithstanding his perfect knowledge of this circumstance, M. Desmarest, in general a very acute observer, commits himself the very identical mistake which he criticises and condemns in Buffon; giving, for a real ant-eater, a plate in the *Atlas to Krusenstern's Voyage*, which, though not of the very first order of engravings, yet very tolerably represents a *coati in the act of killing and devouring a serpent*. This latter circumstance alone is sufficient to show that the animal represented cannot be an ant-eater, even if the engraving itself left the question doubtful, which it does not. It is only surprising that so acute a zoologist as M. Desmarest could ever have committed the error, though, perhaps, not so much so that all subsequent writers should have copied his mistake, without taking the trouble to inquire into the matter.

[Little Ant-eater, *M. didactyla*.]

3. The *little Ant-eater (M. didactyla, Lin.)* is easily distinguished from the other two species, not only by its size, which does not exceed that of the common European squirrel, but likewise by the number of its toes, being four on the posterior and only two on the anterior extremities. The form and general proportions of its body resemble those of the tamandua, only on a very reduced scale. Its whole length, from the snout to the origin of the tail, is but six inches, that of the head not quite two inches, and of the tail seven inches and a quarter. This organ is consequently rather longer than the body: it is thick at the root, and covered with short fur, but tapers suddenly towards the point, where it is naked and strongly prehensile. The muzzle is not so long, in proportion, as in the other two species; the tongue also is shorter, and has a flatter form; the mouth opens farther back in the jaws, and has a much larger gape, the eye being situated close to its posterior angle; the ears are short, rather drooping, and concealed among the long fur which covers the head and cheeks; the legs are short and stout, and the hair very fine and soft to the touch, three-quarters of an inch in length on the body, but much shorter on the head, legs, and tail. The general colour is that of straw, more or less tinged with maroon on the shoulders, and particularly along the median line of the back, which usually exhibits a deep line of this shade. This species is said to have four mammae, two pectoral, as in those already described, and two others on the abdomen. It is reported, nevertheless, to have but a single cub at a birth, which it conceals in the hollow of some decayed tree. The native countries of the little ant-eater are Guyana and Brazil, beyond which it appears not to extend farther towards the south, since Azara is not only unacquainted with it, but imagines, from Buffon's and Daubenton's descriptions, that it must be the young of his tamandua. The habits and manners of this little animal, hitherto very imperfectly known to naturalists, are so well described by Von Sack, in his *Narrative of a Voyage to Surinam*, a book little known to general readers, that we cannot avoid quoting the entire passage which refers to it.

'I have had,' says he, 'two little ant-eaters or fourmilliers, which were not larger than a squirrel: one was of a bright yellow colour, with a brown stripe on the back; the other was a silvery grey and darker on the back; the hair of each was very soft and silky, a little crisped; the head was small and round, the nose long, gradually bending downwards to a point; it had no teeth, but a very long round tongue; the eyes were very small, round, and black; the legs rather short: the fore-feet had only two claws on each, the exterior being much larger and stronger than the interior, which exactly filled the curve or hollow of the large one; the hind-feet had four claws of a moderate size; the tail was prehensile, longer than the body, thick at the base and tapering to the end, which, for some inches on the under side, was bare. This little animal is called in Surinam *kissing-hand*, as the inhabitants pretend that it will never eat, at least when caught, but that it only licks its paws, in the same manner as the bear; that all trials to make it eat have proved in vain, and that it soon dies in confinement. When I got the first, I sent to the forest for a nest of ants, and, during the interim, I put into its cage some eggs, honey, milk, and meat; but it refused to touch any of them. At length the ant's nest arrived, but the animal did not pay the slightest attention to it either. By the shape of its fore-paws, which resemble nippers, and differ very much from those of all the other different species of ant-eaters, I thought that this little creature might perhaps live on the nymphæ of wasps, &c.: I therefore brought it a wasp's nest, and then it pulled out with its nippers the nymphæ from the nest, and began to eat them with the greatest eagerness, sitting in the posture of a squirrel. I showed this phenomenon to many of the inhabitants, who all assured me that it was the first time they had ever known that species of animal take any nourishment. The ants which I tried it with were the large white *termites*, upon which fowls are fed here.

'As the natural history of this pretty little animal is not much known, I thought of trying if they would breed in a cage; but when I returned from my excursion into the country, I found them both dead, perhaps occasioned by the trouble given to procure the wasp's nests for them, though they are here very plentiful: wherefore I can give no further description of them, than that they slept all the day long curled together, and fastened by their prehensile tails to one of the perches of the cage. When touched they erected themselves on their hind-legs, and struck with the fore-paws at the object which disturbed them, like the hammer of a clock striking the bell, with both paws at the same time, and with a great deal of strength. They never attempted to run away, but were always ready for defence, when attacked. As soon as evening came, they awoke, and with the greatest activity walked on the wire of the cage, though they never jumped, nor did I ever hear their voice.'

This valuable account, the only one, as far as we are aware, ever drawn from actual and continued observation of the living animal, leaves us little to desire regarding the history and economy of this highly interesting species. The discovery of the true nature of its food is particularly valuable, and may enable us to have the animal brought alive to this country, a thing which, we believe, has not been attempted heretofore, and which, if attempted, has certainly never succeeded. To procure or carry ants during a long sea voyage is impracticable, but the larvæ of wasps can be obtained in any quantity, and will keep for months; so that the most serious difficulty to the introduction of the little ant-eater being thus removed, it only requires to be guarded from the effects of a colder climate, which may be as easily done in its case as in that of other South American mammals. By the report of Azara also, it is probable that the tamandua lives upon the same food, and may consequently be introduced in the same manner.

ANTACIDS, from the Greek word, 'anti,' *against*, and the Latin word 'acidum,' *an acid*, signify means used to correct acidity in the stomach. Though hydrochloric acid (formerly called muriatic acid, or spirit of salt) is present in a free state in the stomach during the process of healthy digestion, yet under particular circumstances it is apt to be generated in excess. Other acids are also occasionally evolved in the stomach, probably from the fermentation of the articles, as vegetables and fruits of different kinds, by which the acetic acid is produced, or introduced ready formed, in wines, or hard beer; and in certain vegetables, as sorrel, which contains oxalic acid. The most frequent source of acidity, is that first mentioned, the secretion of

acid by the vessels of the stomach. It is, therefore, dependent upon constitutional causes, or the state of the system generally. This is further proved by considering what kind of persons are most subject to it. These are individuals either naturally of a feeble and weak constitution, or who have weakened the stomach and system generally, by excessive indulgence in *good living*, as it is termed, i. e., too much animal food, and wine, unaccompanied by exercise and other counteracting measures. Hence we see these persons, or their children, and even their children's children, subject to gout or gravel, and stone in the bladder. As it has been ascertained (see the works of Mr. Murray Forbes, *A Treatise on Gravel and Gout*, 1786; Wilson Philip, Marcet, Blane, Prout, and Majendie) that these painful diseases have their origin in the tendency of the stomach to the formation of an excess of acid, an inquiry into the causes of this, and the circumstances under which it takes place, is of great importance, as a means of preventing or counteracting them.

When an excess of acid is introduced into the blood, it occasions much irritation of the system generally, and the composition of the blood being different from its natural constitution, the secretions formed from it are unhealthy, proving a further source of disease. In consequence of the composition of the blood being altered, matters usually held in solution by it can no longer be kept in that state, but are precipitated; hence we have *chalk stones*, as they are termed, formed around the joints in gout, and calculi, or *stones*, of different kinds, in the kidney or bladder.

The signs or symptoms of acid being in excess, are not in general limited to the stomach, but shew themselves in several parts of the body. There is heartburn (cardialgia), often followed by eructation, and rejection by the mouth of a fluid so extremely acid, as to cause effervescence when it falls on a marble stone; the bowels are sometimes confined, sometimes too loose; the urine generally scanty, and high-coloured, from which, on standing, a sediment falls down; the skin dry, harsh, and often affected with eruptions of different kinds; and the mind of the patient fretful, and much given to take gloomy views of his health or circumstances; in short, decidedly hypochondriacal.

The medicinal means of remedying this state are all alkaline, either the pure alkalies, or some combination of them—such as solution of potash, or carbonates of soda, potash, magnesia, ammonia, or lime. Where the bowels are not disordered, but the urine denotes that the excess of acid mostly finds an outlet by that channel, the preparations of potash and soda are to be preferred; where the bowels are much confined, magnesia, or its preparations, may be given in conjunction with rhubarb. Nothing is more hurtful than the frequent use of magnesia alone, it being apt to accumulate in the bowels: in the case of an individual much addicted to its use, a mass of it was found after death, lodged in the large intestines, which weighed six pounds. If, on the other hand, the bowels be in a loose state, prepared chalk may be given with advantage, or lime-water, which is a very useful addition to milk, where, from excess of acid, it disagrees, and hence most serviceable for weak children. Should the mind be much depressed, or general languor of the system exist, and no state of stomach be present forbidding its use, ammonia, in some form, may be exhibited.

Such are the medicines by which the effects of an excess of acid may be in some degree counteracted; but the most efficient means of preventing its formation, consist in a strict attention to diet and regimen. Great moderation must be observed in the quantity as well as quality of the food and drink. The plainest and most digestible animal food should be taken once, or, at the utmost, twice a day, and sparingly. Hard-boiled puddings and dumplings must be avoided. Toast and water, or soda-water, or well-fermented beer, or cyder, are preferable as drinks, to wine or ardent spirits, the only one of which last that can be allowed, is Hollands, and never but under particular circumstances, and with the sanction of a medical adviser.

Regular exercise, friction, and every means, such as flannel next the skin, which can keep up a free action of the skin, form a most important part of the prophylactic treatment.

ANTÆ. This is a term used by architects to designate the pier-formed ends of a wall, as in the terminations of the lateral walls in a Greek temple, where a plain face returns on each side, having some relation in general proportion to the columns with which they compose. The antæ (for the

word is used alike in the singular and in the plural) has a moulded and otherwise enriched cap or cornice, and generally a moulded base; in the simple Greek Doric style or order, both the cap and the base-moulding are of few parts, and the enrichments are few, and are confined to the mouldings, which may be either carved or painted; but in the more ornate Ionian or voluted style, both the cap and base of the antæ are in proportion deeper, are in a greater number of parts, and have extrinsic ornaments, besides the carving or painting of the mouldings of the cap, and the fluting or reeding of those of the base. The antæ of the foliated or Corinthian style will perhaps admit of still further enrichment, though the bold foliage and diagonal volutes of the capital of the column should never be placed on the square faces and sharp angles of the antæ. The moulded caps and bases of antæ are, in Greek works, generally continued along the flank walls so as to form the cornice and base of the whole wall, and not of the protruded faces of its ends alone. In Roman works, and in modern imitations of both, breaks are often made on the face of a wall with the caps and bases of antæ, but more frequently with those of columns, and these are called pilasters, though indeed they are but an abuse of the Greek *parastas*, in the plural *parastades*, or antæ. In classical Greek, and in the best Roman works, antæ and pilasters are never either diminished or fluted. The term antæ is of barbarous origin, and it would be difficult to say whether it is derived from a Greek or Latin source; it may be from *antes*, as used by Virgil in the second book of the *Georgics*, where he treats of vine-dressing.

ANTAGONIST MUSCLE, from ἀντί, against, and ἀγωνίζομαι, to strive,—a muscle the action of which is opposed to that of some other muscle. Muscles are the instruments by which, in the animal body, motion is effected. The object of each muscle is to produce some specific motion; among the various motions which are needed in the animal economy, it necessarily happens that some are directly opposite to others, and the muscles which accomplish these directly opposite movements are said to be with relation to each other *antagonists*. When any part of the body is placed between muscles which have an opposite or antagonizing action, the result of the combined action of such muscles is to keep that part steadily in a certain position. The form and position of the human mouth, for example, are maintained, such as they are, in a state of health and during repose of the features, by a number of muscles, composing the lips and cheeks, the action of some of which is directly contrary to that of others: the natural figure and position of the mouth may, therefore, be truly said to be the result of the combined action of a number of antagonizing muscles. The consequence of the disturbance of this antagonizing action is to change the natural form and position of the mouth. This is shown by the effect of paralysis when it affects one side of the face. Paralysis is a disease depriving the muscle of its power of acting. In paralysis of one side of the face, the muscles of that side are deprived of their power of acting; and the consequence is that the muscles of the other side, which retain their usual power, pull the mouth to their side, because they do not meet with the resistance which formerly opposed their effort to do this. Hence comes distortion of the mouth; and distortion is one of the most frequent and striking signs of apoplexy and paralysis, a sign dependent, it is obvious, on the loss of the antagonizing power of the muscles of that part of the body in which the distortion takes place. Sometimes the elasticity of a part is put in opposition to a muscle, and becomes the antagonizing power. The elasticity of the ribs, of the wind-pipe, of the arteries, may be so considered.

ANTALKALIES, from αντι, against, and alkali, an alkali, are means of counteracting the presence of alkalies in the system. An alkaline condition of the system is not an unusual occurrence, and leads, when long continued or extreme, to very serious consequences. The worst of these is the formation of those calculi or stones in the bladder denominated *phosphates*. A tendency to this state exists in most weak individuals: hence most commonly in children, old persons, and females. It may also be brought on by any cause which occasions either temporary or general debility. The prevalence of the depressing passions, as fear, anxiety, or any other which keeps up a *nervous state* of the system, the frequent and continued use of mercury, of powerful purgatives in sickly frames, injuries of the back, or the previous existence of a *very acid state* of the system, will occasionally

give rise to an alkaline state of the system, which, when considerable, shows itself by great general debility, pale countenance, deranged state of the stomach and bowels, and excessive secretion of urine of a pale colour, which, on standing, makes a white deposit. To cure, and prevent the return of, such a state, the causes must, as far as possible, be removed. This is best done by diet, regimen, and appropriate medicines. The diet should be nourishing, mostly animal food, but taken in moderation; and where wine is used, light French or Rhenish should be preferred; hard water should be carefully avoided; saline purgatives, as Rochelle salts, or Seidlitz powders, and indeed all combinations of a vegetable acid with an alkaline base, such as the common saline draught, must be abstained from. The irritability of the system is best lessened by opium and tonic medicines. These last furnish an excellent vehicle for the administration of acids which are the most fitting medicines—either muriatic, nitric, or the citric acid, which is most grateful to children. The phosphate of iron is also a very useful medicine. Purgatives of an active kind should seldom be given; but where the stomach and bowels of children are much disordered, calomel and rhubarb taken frequently for some time are of much service, especially when the phosphate of iron is employed at the same time. Pure, invigorating air, and moderate exercise, are very beneficial, with relaxation from too great mental exertion, where this has preceded the disease.

ANTALO. [See ABYSSINIA, p. 54.]

ANTAR, an Arabian warrior, best known to Europeans as the hero of a romance, translated into English, in 1819, by Mr. Hamilton, oriental secretary to the British embassy at Constantinople. The hero is not a completely fabulous person: he was the son of an Arabian prince, by a negro slave. Born, therefore, to his mother's condition, and for a long time disowned as an Arab, and ill-treated by his father, he yet raised himself to high consideration by his extraordinary strength, courage, and poetical talent. He lived at the close of the fifth and beginning of the sixth century.

The romance of Antar is conjectured to have been put together in its present form, from the original legendary tales, about the time of the famous Caliph Harun al Rashid; and it is still one of the favourite sources from which the professional story-tellers of Egypt, Syria, and Arabia draw their materials. The hero is an eastern Roland, routing whole armies for the love of his mistress. This poem is curious, as presenting an early picture of the manners of the Bedouin Arabs; but there is too much sameness in it to render it, in its English form, very interesting to the reader. (*Introduction to the Translation of Antar.*) [See ARABIAN LITERATURE.]

ANTARCTIC CIRCLE. [See ARCTIC CIRCLE.]

ANTARCTIC OCEAN, a term properly applied to the ocean between the antarctic circle and the South Pole. The word is sometimes used to express generally the cold oceanic regions round the South Pole, without strict regard to the limits of the antarctic circle. Numerous attempts at discovery have been made in these high southern latitudes, [see Cook,] and particularly of late years. The farthest point yet attained is in 74° 15' S. lat. 36° W. long, which was accomplished by Captain Weddell in 1823. The most recent discoveries of land in the Antarctic Ocean were made by Mr. John Biscoe in 1831 and 1832. On February 27, 1831, in 65° 57' S. lat., 47° 20' E. long. Captain Biscoe discovered land of considerable extent, closely bound with field ice, but was not able to approach it within twenty or thirty miles. At the time of the discovery the temperature of the air was 22°, and that of the water 30°: the Aurora Australis was very vivid. This unapproachable land was called Enderby's Land, from the name of the owners of the vessel. On February 21, 1832, Captain Biscoe landed on what is now called Graham's Land, which the discoverer supposes to be of considerable extent: the highest mountain in view, called Mount William, is placed in 64° 45' S. lat. 63° 51' W. long. In front of this high continuous land is a range of small islands, now called Biscoe's Range. No living animals, except a few birds, were found on any of these islands, though there were many birds seen a few miles to the northward. For further information on the climate, &c., and the few pieces of land yet discovered in this part of the ocean, see the articles NEW SOUTH SHETLANDS, SANDWICH LAND, &c., and POLAR SEAS. For an account of Biscoe's voyage, see the *Journal of the London Geographical Society*, vol. iii., from which these facts are taken.

ANTARES, a name given to the bright star marked α in the constellation SCORPIO, which see. In the latitude of Greenwich, it has not more than 124° of altitude when on the meridian, where it is at midnight in the beginning of July.

ANTECE'DENT, a mathematical term used in proportion, meaning the *first* of the two terms of a ratio, in opposition to the *consequent*, or second term. Thus, in the continued proportion:—

$$2 : 4 :: 3 : 6 :: 4 : 8 :: 5 : 10, \&c.,$$

2, 3, 4, 5, &c., are antecedents; 4, 6, 8, 10, &c., are consequents. Antecedents may be made consequents, and consequents antecedents, without altering the truth of the proportion. Thus, if

$$a : b :: c : d,$$

it is equally true that

$$b : a :: d : c.$$

ANTECEDENTIA. When a heavenly body moves contrary to the order of the signs of the zodiac—from Gemini to Taurus, from Taurus to Aries, &c.—it is said to move in *antecedentia*. When it moves according to the order of the signs, it is said to move in *consequentia*.

ANTEFIXA, or ANTEFIXÆ, for this term is more frequently used in the plural, for both singular and plural, than otherwise. Antefixæ are blocks with vertical faces placed along over a cornice, in ancient Greek and Roman buildings, to hide the ends of the covering or joint tiles, and their faces are generally carved with a flower, leaf, or other enrichment, to make them ornamental. The flanks and rounded projection from the eastern end of the church of St. Pancras in London exhibit antefixæ ranged along over the cornice, but without the parts of which they are fitting accompaniments. The fronts of the Travellers' Club-House to Pall-Mall and Carlton-Gardens, also in London, show antefixæ more judiciously composed with the roof, with which they form an ornament to, and help to enrich, the elevation.

ANTELOPE, (*Antelope*, Pallas,) in zoology, a genus of ruminating mammals, belonging to the hollow-horned family, and distinguished by the round, annulated form of their horns, the grace and symmetry of their external proportions, the presence of suborbital sinuses and inguinal pores in the majority of the species, and other less general and important characters. The great extent of this genus, comprising, as it does, above three-fourths of the known hollow-horned ruminants, and the numerous additions which have been made to it since the period of its formation, render it utterly impossible to define it by such simple logical terms as shall at once distinguish it from continuous genera, and embrace all the species which are usually associated with it. It is true, indeed, that most of the characters which zoologists commonly assign to the genus *antelope* are not found either in *bos*, *ovis*, or *capra*, and in so far may be fairly considered as differential, and peculiar to the former genus: but unfortunately they are not in any instance common to all the individual species which compose this group, and consequently cannot be made the basis of a general definition. Hence it is that naturalists, in treating of the genus antelope, have been forced to content themselves with a general description of its most important characters and features, or even to define it by negative characters, such as the absence of a beard on the chin and a dewlap on the throat; and this mode of procedure, however unsatisfactory in general, appears to be unavoidable in the present instance, on account of the peculiar difficulties of the subject.

Perhaps the most general character belonging to the antelopes consists in the form of the horns being round and annulated, or at least never exhibiting the prominent angles and ridges which distinguish those of the sheep and goats. In their particular forms and curvatures, however, they vary in almost every different species, as among domestic sheep they do even in different varieties of the same species. Sometimes they form a single bend forwards or backwards, sometimes they are what is commonly called lyrate, or bend first backwards and then point forwards, in such a manner as, when opposed to one another, to assume the figure of an ancient lyre, the brachia or sides of which instrument were frequently made of the horns of the *dorcas* or common gazelle, as appears from the engravings of antique gems still preserved; sometimes they are twisted into a spiral form, and sometimes the horn itself is straight and surrounded by one or two turns of a prominent spiral wreath.

In many of the smaller species the bony core, or process of the os frontis which is inserted into the hollow sheath of the horn itself, is almost solid, or at least the osseous substance of it is penetrated only by very minute pores. M. Geoffroy St. Hilaire has proposed to make this character the distinctive mark of the genus, and his sentiments upon this subject have been adopted by M. Desmarest and most other subsequent writers, including Baron Cuvier himself; but it has been clearly shown by Colonel Hamilton Smith, that the character is by no means universal, nor even general, all the larger species having the core of the horn more or less cellular, and some as completely hollow as the ox, the sheep, or the goat. In other respects the character proposed by M. Geoffroy is so devoid of influence upon the habits and economy of the animals, and so unimportant even as an artificial distinction, that its practical failure is little to be regretted. A much more important, though unfortunately not a more general character, is found in the presence or absence of horns in the female sex. In this respect the antelopes are as variable as in all their other characters; in both sexes the greater number of them have horns, but at the same time the females of many species are deprived of these organs, and this character, though not universal to the whole genus, is invariably constant in the species which possess it.

The possession of *lachrymal sinuses*, or, as they are vernacularly called with reference to the stag and fallow-deer, *tear-pits*, is another circumstance which distinguishes the greater number of the antelopes, but which, like all their other characters, is far from being general. Many zoologists suppose these organs to communicate with the nostrils, so as to enable the animals to breathe freely during their long and rapid flights when pursued or frightened; some even suppose them to be subservient to the sense of smell, and to serve for detecting the noxious qualities of the numerous poisonous plants which grow in the deserts, or spring up among the rank vegetation of tropical climates. It is certainly true that all these animals possess a most delicate sense of smell, and that no known quadrupeds can surpass, and very few equal, them in the course. Mr. White, in his *Natural History of Selborne*, and Colonel Hamilton Smith in the fourth volume of Griffith's edition of the *Régne Animal*, even assure us that they have observed the air passing backwards and forwards through the suborbital sinuses of the fallow-deer and saumer (*Cervus hippelaphus*) whilst the animals drank with the nose completely plunged into the water; yet, notwithstanding the direct authority of these respectable writers, we are strongly inclined to believe that their observations rest upon some accessory circumstance which escaped their attention at the time, since it is very certain, as is demonstrated by the anatomy of the parts, that no internal communication exists between the lachrymal sinus and the nose, or indeed any other organ. The sinus itself is simply composed of a sack or fold of the skin, of greater or less extent according to the species, but always capable of being opened or shut at the will of the animal, and furnished at the bottom with a gland which secretes an oily, viscous substance of the colour and consistence of ear-wax, but which hardens and turns black upon exposure to the air. The precise functions of these organs are entirely unknown: that they serve some special purpose in the great economy of nature cannot be doubted for a moment by those who are in the least acquainted with the general principles of comparative anatomy, but the exact nature of their function can only be ascertained by those whom fortune has placed in a situation where they may have daily opportunities of observing a great many different species in their natural state and original habitat. All that we know with certainty at present is, that many of the antelopes which are most commonly brought to Europe and preserved in menageries, such as the common Indian antelope and the gazelle, make continual use of this organ when any strange substance is presented to their notice, particularly if it be odoriferous, and appear to derive great pleasure from protruding the lachrymal sinus and rubbing its interior surface against the odorous body. This, and similar observations render it by no means improbable that the organ in question may, in some manner or other, take cognizance of the qualities of matter, and thus be subservient to the intellectual faculties of the animal; but if so, it must be confessed that we are at present entirely ignorant of the precise mode in which it acts.

It has been already hinted that the antelopes are not the

only ruminants which possess suborbital sinuses. In fact, these organs are more universally found in the deer kind than in the present genus; but, on the other hand, as these are the only animals belonging to the hollow-horned family which exhibit this character, it thus becomes sufficiently appropriate, and, as far as it goes, serves readily to distinguish the antelopes from the goats and sheep, with which they are most liable to be confounded. In this respect, as well as in the absence of horns in the females of many species, they form an intermediate link between the rest of the hollow-horned ruminants and the cervine or solid-horned family: so nearly indeed do some species of antelopes approach to the deer kind in general, and so perfectly similar are they in all their most prominent and essential characters, the horns alone excepted, that it is often next to impossible to distinguish the hornless females of the one genus from those of the other. In these cases it is only by such trifling appearances as the form of the tail and ears and the quality of the hair, that we are enabled to form even a tolerable guess as to the genus of the individual, and even these criterions are frequently fallacious, a strong and convincing proof of the close affinity which subsists between these two genera, and of the propriety with which Professor Pallas, on the original formation of the genus *Antelope*, considered these animals as forming the connecting link between the deer and the goats, with the latter of which they had been up to his time associated.

Besides the suborbital sinus, a few species of antelopes possess a different gland, which runs lengthwise between it and the mouth, in a direction for the most part parallel to the plane of the chaffron or face and nose, and secretes a dark oily substance; it is, however, entirely external, and has no internal opening like the lachrymal sinus, nor are its uses better known than those of that organ. It is likewise much less general, being confined to a very small number of species; and, as appears from the observations of M. F. Cuvier and Colonel Smith, sometimes accompanies the lachrymal sinus, and at other times is found alone without any appearance of the latter. The former fact, if it can be relied upon, proves at least that it is a separate organ, and not a mere modification of the lachrymal sinus; and, consequently, it may be fairly presumed that its function, whatever it may be, is likewise different. Another character, but much more generally found to distinguish the antelopes than even the suborbital sinus itself, is derived from the inguinal pores, which are sacks or deep folds of the skin, situated in the groin, opening inwards, and secreting a glutinous substance similar to that of the glands already mentioned. Very few species, indeed, want these pores, but still they are not universal, nor can we form even a probable conjecture regarding their use. A single species, the chamois, (*A. rupicapra*), has a pit or fold of the skin nearly half an inch in depth, opening externally by a small aperture immediately behind each ear, but not provided with a gland, nor appearing to secrete any matter. Baron Cuvier supposes, with great probability, that it was this circumstance which gave origin to the opinion of the ancient Greeks and Romans, so often alluded to by Ælian, Pliny, and other classical authors, that goats breathed through their ears, an opinion repeated by Gesner, Aldrovandus, and other writers of the middle age, and which finds a parallel among modern naturalists in the idea before referred to, that deer and antelopes breathe through their suborbital sinuses.

In the form of the upper lip, an important character among animals which seek their food on the ground, and in which the lips and tongue constitute the only organs of touch and prehension, the antelopes are as variable and inconstant as in the other characters already described. In some species, it forms a broad naked muzzle, as in the ox; in others it is hairy and attenuated, like that of the goat; and finally, it sometimes assumes an intermediate form, and presents a modification of both these characters. The females are furnished with either two or four teats, forming a small udder; they usually bring forth but one at a birth, in a few instances two, and the period of gestation differs according to the species. Few observations, however, have been recorded upon this subject; the nyl-gchau, and some others of the larger species, are known to go with young about eight months, but it is probable that the smaller species do not go longer than the sheep and goat, or about five months. It is very seldom that the males and females in this genus, or indeed among mammalia in general, differ from one another

in colour, but when this does happen, as in the instances of the nyi-ghau and common Indian antelope, the young males always assume the female's colours for the first two or three years of their lives, and only gain the adult colours of their own sex as they advance in age.

The hair of the antelopes is generally short and smooth, and of an equal length over every part of the body; some, however, have manes along the neck and on the shoulders, composed of long bristly hair, either growing upright or reversed towards the head as in the oryx; and a very few species, like the gnu, are furnished with a beard on the chin and throat. The ears are commonly long, narrow, and pointed, smooth on the outside and filled internally with long white hair growing in five longitudinal lines, with four naked black spaces between, and forming the appearance which, in describing these animals, is usually denominated *striated*. The tails are generally short, round and tufted at the extremity, and many species are furnished with little tufts of long black hair, called *scopes* or knee-brushes, upon the upper part of the anterior canons, immediately below the carpal joint.

Generally speaking, the antelopes are gregarious and unite in large herds, either permanently, or at particular seasons of the year, but only for the purpose of migrating in search of more abundant and grateful pasturage; some species, however, reside in pairs or small families, consisting of an old male and one or more females, with the young of the two foregoing seasons. They are always extremely cautious in guarding against surprise, placing sentinels in various directions about their feeding ground, to warn them of the approach of danger whilst grazing or reposing, and their vision and sense of smell are so acute, that it is only by using the greatest caution and circumspection that the hunter can bring them within range of the gun. The names by which the animals themselves are distinguished in all languages, ancient as well as modern, have a direct reference to this quickness of sight, and to the brilliancy of the large black eyes which form so conspicuous a feature in the antelopes. Thus the word *dorcas*, (δορκάς,) the Greek and Roman name of the gazelle, or common Barbary antelope, is derived from the verb *δερκομαι*, to see. The common English word antelope, which zoologists have adopted as the generic name of the group, is a corrupt form of the term *ἀντολόφ*, employed by Eustathius to designate an animal of this genus, and literally signifying *bright eyes*; and, according to the learned Bochart, *Tabitha*, the name of the disciple raised to life at Joppa, is derived from *tzebi*, the Hebrew name of the common gazelle, and alludes likewise to the beauty of her eyes. Among the Greeks and Romans also, as we learn from Agathias, and others, *dorcas*, *dorcalis*, and *dimalis*, all names of different antelopes, were common names of women likewise, bestowed without doubt on account of the remarkable beauty of their eyes; and Prosper Alpinus, and more recent travellers, inform us, that 'Aine el czazel,' *You have the eyes of an antelope*, is the greatest compliment which at the present day an oriental admirer can pay to his mistress. Eastern poetry and romance, as well as the works of the Greeks and Romans, abound with similes and metaphors taken from the form and habits of these animals; they are universally the images of gentleness and timidity, of grace and fleetness. The inspired writer beautifully compares the speed of Asahel to that of the wild gazelle; the Gadites also are said to have been as swift as mountain gazelles—for this is the proper signification of the Hebrew word *tzebi*, improperly translated *roe* in our English version of the Scriptures; and many other instances might be adduced, both from sacred and profane writers. Throughout all parts of the East the fleetness and timidity of the antelope tribe is still proverbial, and furnishes the Persian and Arab poets with images of gentleness, beauty, grace, and affection. The swiftest dogs and horses are left far behind in the pursuit of these animals, and it is only by stratagem that they can be hunted with success. For this purpose the hawk or the cheetah (*felis jubata*) is commonly employed in the East, and the gun or various descriptions of snares and traps by the inhabitants of South Africa. The hawk, by attacking the animal about the head and eyes, harasses it and impedes its flight, till the hunter has time to come up; and the cheetah, like the rest of the cat kind, steals upon it unawares, and seizes it by a sudden spring before it has time for flight. If, however, the first spring misses in its aim, and the antelope escapes, there is no chance of taking it afterwards, and the cheetah, irritated by disap-

pointment, is soothed only with considerable difficulty, and becomes unfit for the chase for some days afterwards. The Bushmen of the Cape often destroy vast numbers of the antelopes with which their country abounds, by poisoning the springs and reservoirs to which they are known to resort, nor is the flesh ever known to be injured by this mode of slaughter; they also shoot them with poisoned arrows, but in this case the parts immediately around the wound must be cut out before the rest of the body imbibes the poison, which would otherwise penetrate through it, and render it unfit for food.

Africa may be considered as the head-quarters of the antelopes. Of this numerous genus, consisting at present of nearly seventy different species, upwards of fifty species inhabit the African continent alone, two or three are common to it and Asia, about a dozen species are peculiar to this latter continent, two inhabit Europe, and one only is found in the new world: the Rocky Mountain goat, described by Colonel Smith under the name of *antelope lanigera*, belongs certainly to a different genus, and has no other character in common with the antelopes, except the round form and small size of its horns. Australia and Madagascar are, as far as we at present know, completely destitute of antelopes, as indeed they appear to be of all indigenous ruminants. The precise nature of the habitat frequented by these animals has nothing of a uniform character, but, as might naturally be expected from the different modifications of organic structure observable throughout the genus, differs according to the particular species. Some frequent the dry sandy deserts, and feed upon the stunted acacias and bulbous plants which spring up even in the most arid situations, where the stony nature of the ground gives a certain degree of adherence to the soil; some prefer the open stony plains, the steppes of Central Asia and karroos of Southern Africa, where the grass, though parched, is still sufficient for their subsistence; some again inhabit the steep rocky mountains, and leap from cliff to cliff with the ease and security of a wild goat, whilst others are found only in the thick and almost impenetrable forests of tropical countries.

The great extent of the genus *antelope* has obliged zoologists to subdivide it into a number of minor groups, or, as they are sometimes called, subgenera; and some have even gone so far as to bestow different names upon each of these different subdivisions. So long, however, as these animals are simply considered as different species of a common genus, this latter practice is neither sanctioned by example in other instances, nor productive of so much practical utility as to justify an exception to the general rule in the present. We shall therefore be so far guided by the example of Baron Cuvier, as to dispense with the names imposed upon the different subgenera of the genus antelope, by Lichtenstein, De Blainville, and other writers; contenting ourselves, like the first-mentioned eminent zoologist, with designating the various subdivisions by appropriate numbers, which have all the advantage of perfectly distinguishing the different groups, without misleading the judgment by false associations, or directing it to mistaken affinities and relations which have no existence, the too common consequences of an inconsiderate application of vague and improper terms. The principles of division and arrangement which we shall adopt are those which appear best calculated to distinguish the different groups in a definite manner, and at the same time to place in contiguity those species which most nearly approximate to each other in their general characters and habits. M. Cuvier has, for this purpose, followed the example of Pennant and Erxleben by adopting simply the curvatures of the horns, and this method has indisputably the advantage of great clearness and simplicity; but it is, at the same time, purely arbitrary, and certainly does not arrange the different species of antelopes according to their natural affinities. The plan of MM. Lichtenstein, De Blainville, and Colonel Smith, is much superior in this respect, but is much more complicated, and their divisions are sometimes vague and indefinitely characterized. We shall endeavour to unite the advantages of both systems, by adopting those characters which are most constant and influential in each, and rejecting all those of a secondary or variable nature.

I. The first of these subgenera or subdivisions of the genus antelope, which has been denominated *anthropomora* by the French naturalists, and *diceranoceros* by Colonel Smith, comprises one or perhaps more species, remarkable

for being the only hollow-horned ruminants in which these organs are provided with a snag or branch in front, like the antlers of the stag or roebuck; a peculiarity of conformation which, as well as the general form and habits of the animals themselves, assimilates them in a great measure to the deer kind, and seems to point them out as the natural connecting link between the solid and hollow-horned families of ruminating animals. Their horns are of a moderate size, hollow only for a short distance from the base, and almost straight till within a few inches of the points, where they bend suddenly backwards and form a complete hook, like those of the chamois: from the root to this bend they are rough and scabrous like the antlers of deer, but the point is black, smooth, and shining, and the prong or antler, which in old animals is situated about half-way up from the root of the horn, is short and compressed, points forwards and a little outwards, and never exceeds an inch or an inch and a half in length. The females are without horns and have four teats, forming a small udder; the lips are hairy and attenuated like those of the goat; there are neither suborbital sinus nor inguinal pores as in the generality of the antelopes, but the fore-knees are furnished with large and copious brushes, and an erect mane of long hair runs from behind the ears half-way down the neck. One of the most remarkable characters of this group, and, with a single exception, peculiar to it among horned ruminants, consists in the total deprivation of accessory or false hoofs, another affinity with the solid-horned family, which approximates it strongly to the giraffes, and forms an additional inducement to place it at the head of the genus antelope. These animals even seem in some manner to connect the otherwise anomalous genera of camels and lamas with the ordinary ruminants, at the same time that they connect the hollow-horned family with the solid-horned, by means of the double affinity which they bear on the one hand to the deer in the form of their horns, and to the giraffes on the other by the absence of accessory hoofs; the latter character being peculiarly confined, among ruminating animals, to the camels, the lamas, the giraffes, and the group of antelopes at present under consideration. Colonel Smith has described two species as belonging to this group, but we have the authority of Dr. Richardson, whose experience entitles his opinion to great weight, for considering the *antelope palmata* of that author, a species founded upon the inspection of a pair of horns in the Museum of the College of Surgeons, as nothing more than a very old specimen of the common species, *A. furcifer*. The same naturalist considers the present group (and though it consists of a single known species only, it is highly probable that the plains of Mexico and California contain one, if not two different species) to comprise the animals long since described by Hernandez under the generic name of *Mazama*; and it is at least certain that one of the species so denominated by the Spanish author very closely resembles the *A. furcifer*; but, on the other hand, we are expressly assured by Hernandez himself that the antient Mexicans comprehended all the deer kind under this term, and the various descriptions which he gives afterwards clearly refer to solid-horned ruminants. The prong-horned antelope seems therefore to have been associated with the deer, on account of its branched horns; but whether the animal referred to by Hernandez be the same as that which is known to the west of the great lakes is a question to be determined by future observers. The only species of which we have any certain knowledge at present is—

1. The PRONGBUCK, (*A. furcifer*, Ham. Smith.) called *cabree* by the Canadian voyageurs, and the *goat* by the fur-traders. This animal measures four feet four inches from the nose to the root of the tail; its height is three feet at the shoulder, and the same at the croup; the ears are upwards of six inches long, and the tail about four and a-half. The horns rise perpendicularly from the skull, immediately above the orbits; they spread outwards, and are perfectly straight till within two or three inches of the points, where they curve suddenly backwards and inwards, forming a small hook, like those of the chamois. The prong is situated upon their anterior face, and in adult animals, about half-way up from the root; below it the horns are strongly compressed, rough and scabrous or pearly, like the antlers of deer; above it they are round, black, and polished. The prong itself is also very much compressed; it is little more than an inch in length, and points forwards, upwards, and a little outwards. The ears are long, narrow, and pointed; the tail short and bushy; the eye large and lively; the limbs long and

[The Prongbuck, *A. furcifer*.]

slender; and the whole form and appearance of the animal peculiarly graceful and elegant. The head, ears, and legs are covered with short close hair of the common description, but that of the body is long and padded, and of a texture altogether different from that of other animals. It is tubular or hollow within like the feather of a bird, but so brittle and devoid of elasticity that it snaps with the smallest effort, and, when pressed between the finger and thumb, crushes like a reed and never regains its original form. It stands directly out at right angles to the hide, is about two inches long on the back, sides, and buttocks, but from the ears half-way down the neck it exceeds six inches in length, and forms an erect mane, equally conspicuous in both sexes. On the nape of the neck, shoulders, back, and hips, it is of a uniform fawn colour for half an inch at the point, and light-blue with a tinge of rose-colour at the root; on the sides, chest, and belly, the latter colour prevails at the root, and the point is of a pure and shining white. The extremities are uniform light fawn-colour throughout, except on the interior of the fore-arms and thighs, which are white. A broad disk of pure white also surrounds the tail, and passes over the croup, and the throat is likewise marked with two transverse bands of the same colour. This is the winter dress of the animal; but Dr. Richardson, who has well described it in his *Fauna Boreali-Americana*, informs us that in summer when the new coat appears, it has at first the ordinary texture and appearance of common hair, and that it only assumes the appearances here described on the approach of the cold season.

The prongbuck inhabits all the western parts of North America from the 53° of north latitude to the plains of Mexico and California, that is, presuming this species to be the *Mazama* of Hernandez: it is particularly numerous on the banks of the southern branch of the Saskatchewan, and on the upper plains of the Columbia river, and a small herd annually visits the neighbourhood of Carlton House, where a few individuals even linger throughout the winter. They are gregarious, frequent the open plains and hills of moderate height, never inhabit closely-wooded districts, and migrate from north to south according to the season. When the ground is clear, their speed surpasses that of most other animals, but a good horse easily outstrips them after a slight fall of snow; they are extremely curious, and the Indians, and, as we are informed by Dr. Godman, even the wolves, know how to take advantage of their curiosity to get within reach of them, by crouching down, and moving forwards; or stopping alternately. The antelopes wheel round and round the object of their attention, decreasing their distance at every turn, till at last they approach sufficiently near to be shot or captured. This habit renders them an easy prey, but as their flesh is not much esteemed by the Indians, they are only hunted in times of scarcity. The females produce one, and occasionally two kids early in the month of June.

II. The second group of the genus antelope is equally without lachrymal sinuses, inguinal pores, or horns in the female sex, and has hairy lips like the group already de-

scribed: but the females have only two teats, the knees are destitute of brushes, and the horns are simple, and without the branch which so prominently characterises those of the prongbuck. This division likewise consists, at present, but of a single species, lately discovered by Mr. Hodgson, the British resident at the court of Katmandoo in Nepaul, and described in the Proceedings of the Zoological Society. It is

2. The CHIRU, (*A. Hodgsonii*, Abel,) believed to be the unicorn of the Bhotias, and supposed by Colonel Smith to be the animal which Ælian describes under the name of *kemas*, (see also Homer *Iliad*, x. 361.) an opinion founded upon very slight and not easily tenable grounds. The whole length of this animal, from the muzzle to the root of the tail, is about five feet, its height three feet; the tail is eight inches long; the head, from the nose to the root of the horns, nine; the ears four inches, and the horns, measured along the curves, upwards of two feet. These grow upright from the skull, are strongly compressed on the sides, bend slightly backwards at first, and afterwards point gradually forwards, thus assuming a lyrate form, but less strongly marked than in the common gazelle; they are surrounded, to within six inches of the points, with from fifteen to twenty annuli, forming prominent knobs in front, but more obscure on the sides and rear; the last six inches are smooth and round, and the points rather attenuated. The legs are long and slender, but the symmetry of the head is destroyed by two large fleshy tumours about half the size of a hen's egg, which grow close to the outer margins of the nostrils, as well as by a profusion of bristly hair which surrounds the mouth and nose. The body is furnished with two different kinds of hair, a long external coat of the usual quality, and a short interior one of fine close wool. The prevalent colour of the latter is uniform greyish-blue, and the outer coat is likewise of the same colour at the base, but it is tipped with reddish-fawn, and thus gives the whole of the upper parts a tawny hue, through which the lower tinge is but faintly visible. The belly and interior of the limbs are white, the nose and face black, and a dark brown band passes down the front of each leg.

The chiru, according to the information obtained by Mr. Hodgson, inhabits the elevated plains of Thibet, but never approaches the mountains, and is altogether unknown on the Indian side of the great Himalayan chain. It is gregarious, residing in herds of many hundreds on the open plains, extremely shy and difficult to approach, posting sentinels in all directions where the herd feeds or reposes, and flying with astonishing velocity on the first alarm or intimation of danger. When brought to bay, however, the males defend themselves with courage, and in confinement are sometimes mischievous, and should be always approached with a considerable degree of caution. Like most other ruminants, they are extremely fond of salt, and during the summer months unite in large herds to visit the beds of this mineral, which abound throughout Thibet, advancing under the guidance of an experienced leader, and as usual posting sentinels to prevent surprise.

III. The third group of antelopes, comprehending more particularly the animal to which the name is originally and properly assigned, is distinguished from the two former groups by the possession of large suborbital sinuses, and by round annulated horns, assuming more or less of a spiral form, but equally confined to the male sex. These animals have likewise large inguinal pores, and hairy, attenuated lips; the females are provided with two or four teats, and the knees of all the species, except one, are furnished with brushes of long stiff hair. They inhabit different parts of Asia and Africa, prefer the open stony plains and steppes, live in families consisting of an old male and a variable number of females, with the young of the two or three preceding seasons, and occasionally unite into flocks of many thousand individuals for the purpose of migration. The best-known species of this division, and indeed of the whole genus, is

3. The SASIN or COMMON ANTELOPE, (*A. cervicapra*, Pallas,) remarkable for the form and beauty of its horns, which compose a spiral of two or more turns, according to the age of the animal. This beautiful animal is, when full grown, about four feet in length, and two feet and a half high at the shoulder; the head, measured from the nose to the root of the horn, is seven inches long, the ears five and a half, and the tail, without the hair, six inches. The legs are long and delicate, the body round, but light, and well formed, the head small the eye large, lively, and expressive,

[The Sasin, or Common Antelope, *A. cervicapra*.]

the ears long and cylindrical, the suborbital sinus particularly developed, and in continual motion, and the horns forming a complete spiral of two or three turns, wrinkled at the base, distinctly annulated in the middle, and smooth for a couple of inches next the points. The females, and young males for the first three years of their age, are of a uniform tawny-brown on all the upper parts of the body, with a light silvery band passing longitudinally from the shoulder to the hips, about six inches below the spine, on either side; the breast, belly, and interior of the fore-arms and thighs are white; as is likewise the under surface of the tail, which is rather broad, and furnished with a small tuft of black hairs at the extremity. After their third year, the males begin to assume the adult colours of their sex, and gradually darken on all the upper parts of the body, till they finally become almost entirely black above and white beneath, the nose, lips and a large circle round each eye being likewise white, but the light bands of the sides completely obliterated. The hair is uniformly short and close over the whole head, body, and extremities, except on the knees, which are furnished with tufts of long bristles, forming small knee-brushes.

The sasins are so swift that it is useless to slip greyhounds after them, as, unless taken by surprise, which their extreme precaution seldom allows, it is impossible to overtake them. And experience has convinced the Indian sportsmen that the dogs are more likely to be injured in the chase than the game. The bounds also which these animals occasionally take, either for their own amusement or over the long grass when pursued, are said to be almost inconceivable. Captain Williamson, in his splendid work on the *Wild Sports of the East*, assures us that he has seen an old buck antelope lead a herd of females over a net at least eleven feet high, and that they frequently vault to the height of twelve or thirteen feet, and pass over ten or twelve yards at a single bound. They reside on the open plains of India, where they can see to a great distance in every direction, live in large families of from five or ten to fifty or sixty grown females to a single male, and when they feed, or lie down to ruminate, detach a number of the young bucks to a distance of two or three hundred yards on every side, to watch over the common safety. Nothing escapes the notice of these careful sentinels; every bush or tuft of grass that might be suspected to conceal an enemy is strictly and attentively examined, and on the first alarm the whole herd betakes itself to flight, following closely in the footsteps of the old buck, and is soon beyond the reach of pursuit. The venison is dry and unsavoury, and being held in small esteem, consequently holds out no inducement either to the occasional sportsman or to the professional Indian hunter. The species extends over every part of India, from the borders of Persia to the most eastern parts of which Europeans have any distinct knowledge. It is found on rocky, open plains, avoids woody localities and the thick cover of the forest, nor is there any certainty of its existing beyond the limits of India, though many zoologists, from Ray to Hamilton Smith, are of opinion that it likewise inhabits some parts of Africa. The fakirs and dervishes polish the horns and form them

into a kind of offensive arms by uniting them at the base; these they wear at their girdles instead of swords and daggers, which their vows and religious character prevent them from using.

4. The SAIGA (*A. colus*, H. Smith) is the only species of real antelope which inhabits any part of Europe; the chamois, though also considered as belonging to this genus, is really an intermediate species, partaking equally of the characters of the antelopes and the goats. The size of the saiga is about equal to that of the fallow deer, the length being four feet; but the form of the body more nearly resembles that of the sheep, being round and heavy, with a large head and short slender limbs, and the whole proportions of the animal want the usual grace and elegance which commonly characterise the antelope tribes. The nose is large, swollen, and cartilaginous, like that of the elk; it is marked above by deep transverse furrows or wrinkles, and, from its great size and protuberance, compels the animal to go backwards whilst feeding. The nostrils are large and open, the ears of a moderate size, the tail from three to four inches in length, and the lachrymal sinuses much smaller than in the Indian antelope. The hair is uniformly long and flowing over the whole body, of a greyish-yellow colour in summer, and greyish-white in winter on the upper parts, and white beneath at all seasons: the knees are furnished with small brushes. The horns of the male are longer than the head; they are semi-transparent and of a light yellow colour, which causes them to be much sought after by the Russians and Chinese for the purpose of making combs, lanterns, and other articles of domestic economy; their form is intermediate between that of the spiral-horned and lyrate groups, being distinctly twisted upon their axis, though without exhibiting the complete spiral threads which characterise the horns of the Indian antelope.

The saiga is mentioned by Strabo (book vii. p. 312. Casaub.) under the name of *colus* (κόλος); the Polish name of the animal, *sulak*, appears to bear some resemblance to the name in Strabo. The Tartars call it *akkar* and the Turks *akim*, which come so near to the Hebrew word *akko*, translated wild goat in our English version of the Scriptures, that we cannot help suspecting that the sacred writers alluded to this animal. In autumn the saigas unite into large flocks, composed sometimes of many thousand individuals, and migrate southward in search of a milder climate and more abundant pasturage; they return northward in small families about the commencement or middle of spring, and generally keep about the vicinity of lakes and rivers, as they drink a great deal, and, as we are credibly assured, by sucking the water through their large open nostrils. This last fact is also stated by Strabo. They like to feed upon acrid, saline, and aromatic plants, and grow very fat during the summer season, but their flesh acquires a disagreeable taste from the nature of their food, and must be allowed to cool after cooking before it is fit to be eaten. The females are gravid about six months, from the end of November to the end of May; they drop their kids soon after their return northward in the spring, and commonly produce one, rarely two, at a birth. They inhabit the open steppes and deserts from the Danube to the Irish eastwards, and as far north as 54° of latitude, and are found in Poland, Moldavia, about the Caucasus and the Caspian Sea, in Siberia, and in Northern Persia. Their eye-sight is said to be defective from the reflection of the dry arid plains upon which they mostly reside; and, though amazingly swift for a short distance, they are soon exhausted and easily run down. They are hunted principally for the sake of their horns and skins, the latter of which, particularly those of the kids, are much valued for the manufacture of gloves. The hunters must always take care to approach them against the wind, as their sense of smell is remarkably acute. With all these precautions it is often impossible to get within shot of these animals, as, like many other gregarious species of antelope, they take care, whilst feeding or reposing, to place sentinels in different directions round their encampment to warn them of the approach of danger. The females, according to the traveller Gmelin, have four teats, but it is not always safe to rely upon the observations of this writer.

5. The DZEREN (*A. gutturosa*, Pallas), the hoang yang, whang yang, or yellow goat of the Chinese, is about the same size as the species last described, being nearly four feet and a half in length, and two feet six inches high at the shoulder; the body also is large and corpulent, and the legs

shorter than is common to the antelopes in general; the horns are black, lyrate and marked to within a short distance of their points with prominent transverse rings; the suborbital sinuses are small; the larynx large and salient, forming, particularly in the old bucks, a prominent lump on the throat; upon the prepuce of the same sex there is likewise situated a bag about the size of a hen's egg, which contains a waxy substance similar to that produced in the analogous organ of the musk animal, but without any kind of odour; the tail is short, and the knees furnished with small bunches of hair, but scarcely sufficiently long and distinct to merit the name of brushes; the summer coat is of a greyish fawn-colour above, and white beneath; that of winter almost entirely white, being tinged but slightly with a greyish-yellow shade on the back and sides. The females resemble the males in colour, but are rather of smaller size, and without horns; they want the sack on the abdomen and have two teats.

The dzerens inhabit the dry arid deserts of Central Asia, Thibet, China, and southern Siberia; particularly the great desert of Gobi, and prefer the most sandy and stony plains, feeding upon such scanty herbage as these localities supply, and avoiding water, to which they appear to entertain a marked aversion. They are remarkably swift, take prodigious leaps, and, when frightened, will occasionally pass over twenty or twenty-five feet at a single bound. In spring and summer they form small families which live apart from one another, but, in the beginning of winter, unite into large flocks, always under the guidance of an experienced old buck. They never run, even when pursued, in a confused crowd, but form single files, and follow closely in the footsteps of their leader; they rarely emit any voice; when taken are easily tamed, and indeed appear to have rather a predilection for the domestic state, often mixing with flocks of sheep, and approaching human habitations during the severity of the winter season: their flesh is tender and well tasted, and they form a favourite object of chase with the Moguls and Tartars. The gestation of the females continues from December till the middle of June, and they produce but a single kid at a birth, which grows slowly, and is long in arriving at maturity. During the first year the young males have neither horns nor any appearance of the protuberance on the throat from which the specific name of *gutturosa* is derived; but these organs are gradually more and more developed in proportion as the animal advances in age, till at last, in very old animals, the laryngeal protuberance attains the dimensions of five inches in length by three in breadth, and assumes the appearance of a large and deformed goitre. The females differ from the males by the absence of this protuberance as well as by the want of horns. Gmelin denies the antipathy to water which Messerschmid attributes to this species, and affirms that, when pursued, the dzerens do not hesitate to throw themselves into the first river they meet with, and that they swim remarkably well. The physical nature of the arid sandy plains which they frequent, in preference to all other situations, may probably have given rise to this presumed antipathy to an element which they seldom encounter, as well as to the marked antipathy to woody localities likewise attributed to them, trees and rivers being equally unknown in the indigenous habitate of these animals.

6. The PALLAH (*A. melampus*, Lichtenstein) is a magnificent species of South Africa, discovered by Professor Lichtenstein during his travels in Caffraria, and since found in the Booshuana country on the elevated plains of Latakoo, by Trutell, Somerville, and Burehell. It is upwards of four feet and a half in length from the nose to the origin of the tail, and three feet high at the shoulder; the horns have an irregular lyrate tendency, bending first forwards and very much outwards, then with a large circular sweep inwards, and finally pointing forward again, approaching within three inches of one another at the tips, after being nearly a foot distant in the middle: they are about twenty inches long in adult animals, and surrounded for two-thirds of their length with irregular rings, often splitting into two, and forming prominent knobs on the front of the horn, but frequently obliterated, and always less strongly marked on the sides, which are slightly compressed. In the beautiful drawing of this animal given in Daniel's *African Scenery*, the horns are represented with an unnatural angular bend, which has misled many describers, and caused even Colonel Smith to describe them as forming an obtuse angular bend, though he has himself given an accurate drawing of the

[The Pallah, *A. melampus*.]

pair which we have here described, and which certainly exhibit no appearance of the sudden angle attributed to them, which probably arose from the particular position in which Mr. Daniel's figure was drawn. The horns for a third of their length towards the points are black, smooth, and polished. The head, back, flanks, and outer surface of the legs and tail are of a deep rufous colour; the lips, eyebrows, interior of the ears, breast, belly, interior of the thighs and arms, and the region below the tail, white; the back is marked longitudinally by a band of deep shining black, which divides on the croup and passes down along each hip in the form of a crescent, separating the pure white of the buttocks and interior of the thighs from the general rufous colour of the upper parts; the outside of the knee and heel are likewise marked by brilliant black spots, which contrast strongly with the general rust-colour of the extremities, and from which the animal derives its specific name of *melampus*. The ears are very long, particularly in the females, which are without horns, and of a smaller size than the males, but similar in other respects; the ears are covered on the outside with short red hair, bordered and tipped with black, and the knees are without brushes. We are as yet very imperfectly acquainted with the characters of this magnificent species of antelope, so that it is not without considerable doubt, and only on the authority of Colonel Smith, that we venture to include it in the present group.

The palla inhabits Caffraria and the country of the Bachapins or Booshuanas, never descending farther south than the Koosges valley in the one direction, and the Kamhanni mountains in the other. They reside on the open plains in families of six or eight individuals, run with amazing swiftness, and occasionally leap like the springbuck, which, according to Mr. Burchell, they much resemble in their general habits and manners. They are extremely numerous on the elevated plains in the neighbourhood of Latakoo, and constitute a favourite object of the chase with the natives, as their flesh, though deficient in fat, is well-tasted and wholesome. *Pallah* or *phaala* is the Bachapin name of the animal, but the mixed Hottentots, who travel into that country from the Cape, distinguish it by the Dutch term *roodebok* or redbuck, on account of the prevailing colour of its hair.

IV. The fourth subdivision or group of antelopes contains a single species, which differs from the last group principally by its small size, short straight horns, knees without brushes, and in the females being provided with four teats. The upper lip is hairy and attenuated; the lachrymal sinuses open externally by small circular apertures, about half an inch from the inner canthus of the eye, and there are no inguinal pores.

7. The MADOQUA. (*A. Saltiana*, Blainville.) This is perhaps the smallest of all horned animals, being scarcely the size of a good English hare. It measures two feet in length from the nose to the root of the tail, and about fourteen inches in height at the shoulder, the height at the croup being about an inch more. The length of the head from

the nose to the ear is five inches, that of the horns three, the ears are two inches and three-quarters long, and the tail an inch and a half. The horns of the male are situated in the plane of the forehead; they are very sharp-pointed, almost insensibly bent outwards and forwards, provided on the inner anterior margin with a prominent sharp ridge, which runs from the base to within a quarter of an inch of the points, and annulated for about two-thirds of their length from the roots. The females are without horns, but have, in common with the males, a tuft of long stiff hair standing upright from the crown of the head, and forming a small crest, particularly remarkable in the females, from their not being furnished with horns; the hair on all other parts of the body is short, close, and smooth, except on the hind face of the hips and thighs, where it is rather longer, and radiates outwards and round the tail, its pure white colour contrasting agreeably with the colours of the croup and thighs; the face, forehead, and legs, as well as the tuft of long hair between the horns, are of a bright and deep red, as are likewise the backs of the ears; the neck, shoulders, flanks, rump, and outsides of the thighs, are of a clear grey colour, like that of the American grey squirrels, each hair being annulated with alternate rings of black and white: the back, from the shoulders to the rump, is a deep reddish brown, and the breast, belly, interior of the fore-arms and thighs, and hinder surface of the hips, of the most pure unmixed white, forming altogether a variety, clearness and brilliancy of colouring rarely met with among quadrupeds; the tail is very short, being in fact little more than a mere stump; the ears are round and nearly the length of the horns; the hoofs small, well-formed, and, like the horns, of a deep black colour; the forehead is perfectly flat, and the head is compressed suddenly below the eyes, and tapers to a small and attenuated snout; the legs are long in proportion to the weight of the body, and so small that they scarcely equal the little finger in thickness.

[The Madoqua, *A. Saltiana*.]

The madoqua is found in all parts of Abyssinia, where it was originally noticed by Bruce, who discovered it in the country about the sources of the Abawi or eastern branch of the Nile. Mr. Salt afterwards procured specimens in the mountains of Tigré, and sent the horns and legs to the British Museum, where they were observed by De Blainville, and described under the specific name of *Antilope Saltiana*, in compliment to the distinguished traveller who procured them. More recently complete specimens have been brought to Europe by Rüppel, and Hemprich and Ehrenberg, and the species has been well described and beautifully figured both by these travellers and in the *Darstellung neuer Oder wenig bekannter Säugethiere* of Professor Lichtenstein. Little is known regarding the habits of this species. It is said to live in pairs in mountainous districts; and Pearce informs us that many of the Abyssinians object to eat its flesh, from a superstitious belief of its being often found in the society of monkeys and baboons.

V. The fifth group comprises two species at present very imperfectly known, and introduced into the present article on the authority of Colonel Hamilton Smith, the only na-

turalist who has hitherto observed and described them. They are distinguished by moderately-sized lyrate horns, confined, as in the groups already described, to the male sex; by large suborbital or lachrymary sinuses, by brushes on the knees, two teats in the females, and probably inguinal pores; but the form of their upper lip differs from that of all those which we have described, and, instead of being hairy and attenuated as in the goat, terminates in a round naked muzzle, like that of the stag or roebuck, thereby indicating a decided difference in the habits and mode of life of these animals, more especially as regards the nature of their food. But for this circumstance, and the absence of horns in the female sex, another character which has a powerful influence upon the economy of ruminating mammals, the presence of the lachrymal sinuses, the number of teats, the existence of knee-brushes, and, above all, the lyrate form of the horns, would approximate the species at present under consideration to the group which includes the common gazelle, the springbuck, and other kindred species; but the characters attributed to them by Colonel Smith not only indicate a difference of food, but likewise a decidedly different habitat—the thick forest and the grassy meadow, instead of the barren stony hills and the parched and burning desert. All the details concerning their habits, as well as their local names, are however unknown, and it is only from their zoological characters that we are enabled to deduce a few facts regarding their economy.

8. *A. forfex*, H. Smith, supposed by its describer to be the species noticed by Pennant under the name of the Gambian antelope, and which that author identifies with the kob of Buffon, is said to be rather larger than the springbuck, the height at the shoulder being rather better than two feet, and the outward form and appearance similar to those of the kvel. The horns are about a foot long, black, and annulated for the first two-thirds of their length, smooth and pointed on the remaining portion; they stand close together at the base, bend slightly forwards at first, and then, with a wide sweep onwards, finally pointing inwards and forwards, and resembling in front the figure of a pair of forceps. The head is broad across the orbits, and measures about ten inches in length; the eyes large and black; the ears rather wide, open, slightly pointed, and filled internally with a bunch of long white hair; all the upper parts of the body are fulvous brown, darkest on the face and hips, all the under parts white, the latter colour being separated from the former by an indistinct dark stripe on the flanks; the legs are marked in front with a brown streak terminating in a black spot on the fore pasterns, and on the hind-legs extending but a short distance up the canon bones; small dark brushes protect the knees; and the tail, about six inches in length, is white beneath, light brown above, with a dark line down the middle and a black tuft at the extremity. The only specimen observed was brought from the west coast of Africa, and formerly exhibited at Exeter Change; it was remarkably timid, and of a mild, engaging disposition.

9. *A. adenota*, H. Smith, which this author identifies with the kob of Buffon, but certainly without sufficient grounds, since the kob has no lachrymal sinuses, whilst in the present animal they are, by Colonel Smith's own description, particularly long and open, is a species described from a pair, male and female, formerly in the Exeter Change collection, and distinguished by the peculiar manner in which the hair is directed upon the body, whirling round a small centre on the loins, and reversed or couched forwards on the back, upwards on each side of the neck, obliquely upon the flanks, and downwards on the hips. The general colour is a uniform fulvous bay above and white below, with a dark list down the front of the fore-legs, and a black ring round the hind canons immediately above the spurious hoofs. The tail is short and entirely covered with long black hair, and the lips, chin, and a space round the eyes are marked with white. The horns of the male rise immediately above the orbits, and are about nine inches in length; the first two-thirds are marked with ten rings, forming prominent knobs in front, but almost obliterated on the sides and behind; the superior third is smooth, black, and rather bluntly pointed; they are a little striated between the annuli and rather compressed on the sides; their direction is at first nearly in the plane of the forehead, but they afterwards spread outwards and backwards, with the points finally bending almost imperceptibly forwards, so as to assume, when seen in front, the figure of a common pitchfork. The

female is without horns, but in every other respect perfectly resembles the male. The pair observed by Colonel Smith were brought from the west coast of Africa, and were excessively shy and timid.

VI. The sixth subdivision of the antelope genus is distinguished by a round naked muzzle, large lachrymal sinuses, and horns confined to the male, but particularly by the number of the horns, which amounts to four, forming the only instance in which horned animals in a state of nature possess more than two of these organs. The inguinal pores and number of teats in the females have not been observed; the knees are without brushes. The group contains at present but a single authentic species, the two described by Dr. Leach and Colonel Smith being but different ages, or at most different varieties of the same animal.

10. The CHICKARA, (*A. quadricornis*, Blainville,) well-described by General Hardwicke in the *Linnaean Transactions*, is about two feet nine inches in length from the muzzle to the root of the tail; the tail itself is five inches long, and the height at the shoulder about one foot eight or nine inches. The superior or common horns are about three inches long, smooth, black, pointed, erect, and moderately divergent, bending very slightly forwards, and without the least indication of annuli. The spurious or additional pair of horns are placed in front of these, immediately between the orbits, and consist of short, erect, blunt stumps, about three-quarters of an inch in length, an inch and a half in circumference at the base, and of the same smooth and black appearance as the real horns. The head is seven inches and a half long, the ears four inches and three-quarters, erect and pointed; the general colour of the upper parts is uniform bright bay, and that of the under parts silvery white, more or less mixed with sandy-coloured hairs; the lips are bordered with black. The females differ from the males by the absence of horns, and likewise by being of a lighter colour, which character is conspicuous at a very early age and continues throughout life.

This species, called chickara by the Hindoos, and chouka by the Nepalese, is common in all the wooded parts of India, particularly in Bengal, Bahar and Orissa; it is monogamous, and lives in pairs, in the forests and thick jungle, being exceedingly wild and active, and rarely suffering a state of confinement unless taken young. During the rutting season the male becomes particularly machievous, and it is then dangerous to approach him, as he butts at everything within his reach; the female produces two young at a birth, but the period of gestation has not been recorded. Baron Cuvier supposes, and apparently with reason, that the antients were acquainted with this species, and that the *Four-horned Oryx* of Ælian refers to the modern chickara.

VII. The seventh group includes a number of species which differ from the last, principally in the number of the horns, being two only, short, round, smooth, and slightly bent forwards. As in all the species hitherto described, they are wanting in the females. The head is terminated by a distinct, well-formed, naked muzzle, the lachrymal sinuses are large and conspicuous; one species only is without inguinal pores; another differs from the general type in the possession of knee-brushes, which are commonly wanting, and the females are universally provided with four teats, forming a small udder. A single species inhabits India; all the others are African, and reside on the open rocky plains, or in the gorges of mountain glens, sometimes bounding from cliff to cliff with all the ease and security of the ibex. These animals are generally monogamous, and associate in pairs or small families, but never unite into large herds like the saiga and springbuck, nor do they migrate from place to place like these species.

11. The NYL-GHAU, (*A. picta*, Pallas,) one of the largest and most magnificent antelopes known, being upwards of four feet high at the shoulder, inhabits various parts of India, whence it has often been brought to England, where it lives and breeds, and is not an uncommon animal. The face of this species is long and narrow, the muzzle large and naked, the horns about seven inches long, small, round, and black, rather distant at the base, nearly parallel throughout their whole length, pointed and slightly curved forwards. They are perfectly smooth and without annuli, but rather triangular at the base, and gradually rounded and attenuated towards the points. The lachrymal sinuses are large, the ears seven inches in length, broad and rounded like those of an ox, the neck deep and compressed like that of the horse,

[The Nyl-Ghau, *A. picta*.]

not round and cylindrical as in the stag and most other antelopes, and the tail broad, equally covered with hair on the sides and at the root, but terminated by a long black tuft, and descending to the houghs. The legs are small and well-formed, the anterior rather longer than the posterior, and the spinous processes of the dorsal vertebrae so much elevated between the shoulders as to give the animal the appearance of having a small hump. When at rest, the feet are gathered close under the body, and the tail turned in between the hind legs. The hair is uniformly short and close upon every part of the head, body, and limbs, excepting along the top of the neck and on the shoulders, where it is long, stiff, and upright, forming a thin erect mane which extends from between the ears half way down the back; and on the middle of the throat, where there is a species of beard composed of stiff bristly hair. The general colour is a uniform slaty blue on the upper parts in the male, and tawny red in the female, on the under parts uniform white in both sexes; the limbs and face are almost brown, and the lips, chin, and under surface of the tail white. There is a large white spot on the throat, and two smaller ones on the cheeks under the lachrymal sinuses; and the pastern joints are marked in front with one, and in rear with two conspicuous spots of the same colour, which contrast strongly with the dark brown of the surrounding parts, and have suggested the specific name of *Antelope picta* which has been given to this animal.

The nyl-ghau resides in the dense forests of India, whence it occasionally makes excursions very early in the morning or during the night, to feed upon the corn-fields of the natives which happen to be situated in the vicinity of the jungle. It is a vicious animal, of very uncertain temper, and as it is both powerful and resolute, and frequently turns upon its pursuers, it is seldom made an object of chase except by the native princes, who employ elephants for this purpose, or enclose the game in nets. The usual method which the shecarries or professional hunters employ for its capture, is to shoot it from an elevated platform when it comes out at night or early in the morning to feed on the confines of the jungle; this being likewise their mode of destroying tigers, wild boars, and other beasts which they dare not attack openly. Even in confinement, and when domesticated from birth, the violent and changeable temper of the nyl-ghau cannot be trusted. Previous to making its attack, it drops upon the fore-knees, advancing in this position till within a proper distance, and then darting suddenly forwards with the velocity of an arrow, and with a force which no ordinary animal can withstand. Yet, notwithstanding its vigour and resolution, it is the most common prey of the tiger, which the shecarries often destroy in the very act of devouring the mangled remains of this animal; for, when these are discovered, the hunters always erect their platforms in a convenient situation in the neighbourhood of the carcass, knowing, by experience, that the tiger is sure to return on the following night to glut himself at leisure with the produce of his previous chase. The nyl-ghau has often bred

in confinement, both in this country and in India: the period of gestation lasts for eight months, and two young are most commonly produced at a birth. At first the young males are of the same reddish-brown colour as the females, and only assume the greyish-blue shade proper to their sex, on arriving at maturity: their growth is, however, rapid, and they attain their adult size in the second or third year of their age.

12. The OUREBI, (*A. scoparia*, Schreber,) called *bleekbok*, or *palebuck* by the Dutch colonists at the Cape, according to Professor Lichtenstein, is a much smaller species than the nyl-ghau, and differs from all the other species of the present section by the large brushes which, in common with many other antelopes, it has upon the upper end of the canons, immediately below the knees, and from which it derives its specific name of *A. scoparia*. It measures three feet eight inches in length from the muzzle to the root of the tail; the length of the latter is three inches and a half, that of the head seven inches and a half from the muzzle to the root of the horn, of the horns themselves five inches and a quarter, and of the ears three inches and three-quarters. The height at the shoulder is one foot ten inches, at the croup nearly two feet, and the size of the animal, as well as its general form and proportions, are nearly those of the roebuck, only that the head is longer and more slender. The horns are awl-shaped, sharp, slender, nearly straight and bending almost imperceptibly to the front; they are surrounded at the base with a few obscure wrinkles, succeeded by five or six well-defined rings, but are smooth and black throughout the greater part of their length, and end in very sharp points. The general colour of the upper parts is a uniformly pale yellowish-brown, darker in some individuals than in others; all the under parts, as well as the chin, lips, and a longitudinal streak over the eyes in the form of eyebrows, are white, and this colour likewise spreads over the posterior surface of the hips. The tail is covered with long bushy hair of a jet black colour, forming a marked and prominent contrast with the white of the buttocks; the ears are edged with a narrow border of dark brown, and immediately beneath their opening at the root there is a remarkable bald or naked spot of an oval form on each side of the head.

The ourebi inhabits the open plains of South Africa, and without being positively gregarious, is fond of the society of its own species. It is found chiefly in the eastern districts of the Cape colony towards Caffraria, and its flesh, though dry and destitute of fat, is esteemed one of the best venisons of the country. Great numbers of these animals are found on the plains about Zwartkops bay. When feeding, they straggle confusedly over the plain, and appear to be in company rather accidentally than by intention; when alarmed also, they do not fly together, but each runs off by itself in whatever direction it thinks most secure from danger for the moment. If the *antelope montana* of Rüppel, generally identified with this animal, be in reality the same species, it would appear to extend along all the eastern coast of Africa, from the southern confines of the continent to the banks of the Bahr el Abiad, or White Nile, close to which Rüppel procured his specimens.

13. The STRENBOK (*A. tragulus*, Lichtenstein) is one of the most graceful and elegant of the antelope tribe. Its legs are longer and smaller in proportion to its bulk than in any other species; its body is compact and well made: its head small, pointed, and ending in a well-formed naked muzzle, and its tail reduced to a mere tubercle, scarcely perceptible among the long hair of the croup and buttocks. The whole length, from the muzzle to the root of the tail, is about three feet four or five inches; that of the head, from the muzzle to the base of the horns, four inches, and from the same point to the root of the ear six inches, the tail being an inch and a half long, and the horns four inches. The height at the shoulder is one foot seven inches, and at the croup one foot nine. The colouring of this species is altogether peculiar, and alone sufficient to distinguish it from all other ruminants. In general, it is a reddish fawn-colour on the upper parts of the body, but this seems to be glazed, or, as it were, overlaid on the shoulders, back, sides, and hips with a light dun or silvery brown hue, arising from the hairs in these situations being tipped with that colour: the nose and legs are dark brown, the breast, belly, and interior of the fore-arms and thighs white; the hair of the forehead is long and of a deep red colour, and a remarkable black line passes from the root of each horn backwards, uniting

between the ears, and forming an obtuse angle equally as conspicuous in the hornless females as in the horned males, and affording an excellent criterion by which to distinguish the species. The horns of the male are small and round, furnished at the roots with a few faintly marked wrinkles, but smooth and polished throughout the greater part of their length, and ending in extremely sharp points, almost imperceptibly bending forwards. The ears are extremely large for the size of the animal, being nearly half as long again as the horns, and broad in proportion. But perhaps the most remarkable character of the species, and certainly that which most definitely distinguishes it from all the other ruminants with which it is at all likely to be confounded, though it has hitherto escaped the notice of observers, is the total absence of spurious hoofs, both on the fore and hind feet, a character which we have already found in the prongbuck, and which, as far as we are aware, no other ruminating animal of the hollow-horned family possesses.

The steenbok resides in pairs on the stony plains and mountain valleys of South Africa, not, however, frequenting very elevated or rocky localities, as its colonial name of steenbok, or stonebuck, would seem to imply. On the contrary, it prefers the dry open flats, covered here and there, it is true, with large rocks and boulder stones, but likewise interspersed with clumps of stunted bushes and underwood, which furnish it with cover. This is the general character of the South African plains in the neighbourhood of Cape Town, as well as of the gorges of the moderate hills and mountains, and it is in such situations that the steenbok is most commonly found. This animal is, moreover, remarkably shy and timid, runs with extraordinary swiftness, and when pursued will frequently bound over a space of twelve or fifteen feet at a single leap. When closely pressed, and without any further means or power of escape, it will hide its head in the first hole or corner it happens to meet with, and thus patiently resign itself to its fate. Though it cannot be called a rare animal at the Cape, it is nowhere particularly common, being much hunted on account of the delicacy of its flesh, which furnishes excellent venison, and great numbers of the young being destroyed by eagles and other birds of prey. Colonel Smith has described the young of the steenbok as a different species, by the name of *A. rufescens*; and the *A. pallida*, or *A. pediocragus*, of Afzelius, appears to differ in no respect from the adult of the present animal, the really distinctive characters of which have been hitherto very imperfectly reported.

14. The GRYSBOK (*A. melanotis*, Lichtenstein) is a species closely allied to the steenbok, but rather lower on the legs and more heavily made. The whole length of the body is nearly three feet, that of the head, from the muzzle to between the ears, six inches; the height at the shoulder is one foot five inches and a half, and at the croup one foot seven and a quarter; the horns are two inches and a half long, and the ears five inches. The head, as in the steenbok, contracts suddenly before the eyes, and ends in a pointed muzzle; the horns are situated immediately above the orbits, straight, upright, pointed, and shining, with two or three small annuli at the roots; the ears are long, wide, and open, and the tail, almost tuberculous, is concealed among the long hair which passes backwards over the hips. The hair of the body is universally long, particularly on the hind quarters; on the head and extremities it is, on the contrary, remarkably short. All the upper parts are of a deep crimson red colour, thinly but regularly intermixed with long coarse hairs of the purest white, giving the whole animal a hoary appearance, expressed by its colonial name of grysbok, or grey-buck, and forming altogether a character not easily mistaken; the inferior parts are uniform light sandy brown or red, the head and extremities fawn-colour; the muzzle, the openings of the lachrymal sinuses, and an obscure circle about the eyes, as well as a mark upon the occiput of some specimens are black, as are likewise the backs of the ears, which are nearly naked, with a few very short grey hairs thinly scattered over them.

The habits of the grysbok are in most respects similar to those of the steenbok. It lives in pairs upon the plains, never unites into troops or flocks, and conceals itself in clumps of underwood, whence it is not easily driven, lying close like a hare in her form, and seldom moving till almost trodden on. It is common in most parts of the colony at the Cape, and being less swift than the steenbok is more easily captured; its venison is much esteemed, though, like the generality of antelopes, destitute of fat.

15. The KLIPSPRINGER, (*A. oreotragus*, Forster,) called kainsi by the Hottentots, is an antelope which inhabits the most barren and inaccessible mountains of the Cape, and appears to supply in South Africa the place of the chamois and ibex. The entire length of this animal, from the muzzle to the root of the tail, is three feet two inches. its height twenty-one inches at the shoulder, and about an inch more at the croup; the horns are three inches and a half long, the ears four and a quarter, and the tail three. The head is short and small, compressed on the sides, and suddenly contracted immediately in front of the orbits, ending in a small, round, naked, black muzzle; the lachrymal sinuses open by a moderately-sized circular aperture; the horns of the male are perfectly straight and smooth throughout the greater part of their length, having three or four small but distinct annuli surrounding their roots; the ears are large, open, and rounded at the points; the eyes large and dark, and the tail appearing externally only by a brush of hair which clothes it. There are neither inguinal pores nor knee-brushes, but in place of the latter the knees of some specimens exhibit a naked callous patch, probably occasioned by rubbing against the rocks. The general colour of the animal on all the upper parts of the body is a lively and pleasing mixture of yellow and green, resulting from each hair being individually surrounded by alternate rings of these two colours; the under parts of the body are light sandy-red, tinged with yellow; the interior of the ears is filled with long white hair, a narrow black border surrounds their edges, and the eyes are encircled by the same colour. The hair of the body is long, padded, and stands perpendicularly out from the hide; that of the head and extremities is shorter, and lies in the usual direction; in quality the latter also resembles the hair of common animals, but the texture of the hair which covers all the upper surface of the body and neck is altogether peculiar, being similar to that of the prongbuck already described. It is round and hollow internally, and so fragile that it breaks with the slightest touch, crushing like straw when pressed between the fingers, and so deficient in elasticity that it never regains its original form. The tail is covered with a small bush of hair of the same description, but so short as to be scarcely perceptible among the long hair of the hips. The legs are more robust than in most other species of antelope, and the hoofs, instead of being pointed and flat beneath, are perfectly round and cylindrical, being worn only at the tips, upon which alone the animal treads. This peculiarity of structure in the hoof, and the rigid form of the pastern joints, which are perfectly stiff, and in a straight line with the canons, account for the amazing agility which the klipspringer displays in bounding among the most dangerous rocks and precipices.

The peculiar habitat of this species makes it impossible to hunt it with dogs, but it is easily shot as it exposes itself upon the naked rocks, and great numbers of the young are destroyed by eagles and other birds of prey which inhabit the same localities. In consequence of this, the animal is by no means common, and is becoming every day more scarce in situations where it most abounded formerly; the excellence of its venison and the value of its hair, which is held in great estimation for stuffing saddles and mattresses, hold out a powerful inducement to its destruction.

16. *A. acuticornis*, De Blainville. This species is only known from a mutilated skull and horns in the Museum of the College of Surgeons in London. The horns are round, vertical, very sharp-pointed, and perfectly smooth, without the least appearance of annuli at the base, nearly parallel throughout their whole length, and moderately curved forwards; they are three inches long, and little more than an inch in circumference at the base. The sinciput is narrow, square, and much elevated. These characters show the fragment in question to have belonged to a young animal. Colonel Smith adds, that it was brought from India, and considers it to be the species which Mr. Johnston alludes to in his *Sketches of Indian Field Sports* under the name of small deer, and which that author says is an inhabitant of the dense forests of the Rhamgur country.

17. *A. subulata*, Smith, is another species only known from the horns, which were likewise brought from India to the College of Surgeons, where they were observed by Colonel Smith, and afterwards figured and described by him in the fourth volume of Griffiths's *Animal Kingdom*. These horns are four inches and a half in length, an inch in circumference at the base, smooth, black, and sharp-pointed.

They are nearly vertical on the forehead, bending moderately outwards in the middle, and their points turning slightly inwards, and thus assuming something of the figure of a shoemaker's awl. Their distance at the base is one inch and two lines, and in the middle about two inches.

VIII. The eighth group into which we divide the genus *antelope* is distinguished from all those which precede it by the total absence of lachrymal sinuses, and by the beautiful spiral form of the horns, surrounded throughout the greater part of their length by a prominent wreath. The species comprised in this subdivision have likewise distinct naked muzzles and inguinal pores, but they want knee-brushes, and the females are without horns and provided with four mammae. They inhabit the forests of South and West Africa, and are the only antelopes distinguished by the variety of their colours, being more or less spotted and ribbed with white upon a dark or fallow ground. They live in pairs or small families.

[The Koodoo, *A. strepsiceros*.]

18. The Koodoo (*A. strepsiceros*, Pallas) is a magnificent animal of South Africa, and one of the largest of the antelope genus, measuring upwards of eight feet in length, and being four feet high at the shoulder. The horns of the male are particularly magnificent; they are nearly four feet long, and beautifully twisted into a wide-sweeping spiral of two turns and a half, surrounded by a prominent wreath which follows all their windings, and is gradually obliterated towards the points, which are rather blunt and directed outwards. They are thick at the base, and marked for some distance up with irregular wrinkles, but not annulated, dark brown at the bottom, black in the middle, and the extreme points white. They spread boldly and widely outwards and are usually carried couched on each side of the back, on account of their great weight. The whole make of this animal is heavy; the head large and terminated by a broad muzzle, the ears broad and slouching, the limbs thick and robust, and the whole external appearance more nearly resembling that of an ox than of an antelope. The ground colour of the back and sides is a light fallow-brown, with a narrow white ribbon along the spine, and eight or ten similar bands descending from the back and passing obliquely down the sides and hips; the belly and under parts are pale silvery brown. On the neck and withers is a thin spare mane of a brown colour, and the chin, throat, and breast are furnished with similar long hairs, forming a species of beard. The cheeks are marked with two or three round white spots, and a narrow grey line passes from the anterior angle of the eye down towards the muzzle. The tail is moderately long, and equally covered with short hair.

This magnificent animal inhabits the woody parts of Caffraria, principally along the banks of rivers, to which it readily takes when pursued, and swims well. It lives in small families of four or five individuals, is never found on the open plains, much less on the mountains, as M. Desmarest erroneously supposes, and feeds on the shoots and leaves of young trees. Though a heavy animal, and by no means rapid in the course, it leaps with surprising agility,

and has been known to clear a door of ten feet high at a single bound. The males are not deficient in courage, but defend themselves resolutely when driven to bay; when taken young, however, they are readily domesticated, and show no inclination to regain their original freedom. The females produce one young at a time.

19. The Boshbok (*A. sylvatica*, Sparrman) is a much smaller animal than the koodoo, measuring about four feet from the nose to the root of the tail, and being two feet six inches high at the shoulder. The horns are nearly a foot in length, thick at the base and gradually attenuated, but ending in rather blunt points; they are twisted on their own axis, but do not form the wide-spreading spiral curves so remarkable in those of the koodoo: from the base, however, two sharp, prominent wreaths, one on the outer and the other on the inner surface, wind spirally round them for the first two-thirds of their length, and are gradually obliterated towards the points, which are smooth and polished. The ears are large and rounded at the tops, the limbs robust but clean and well-formed, and the tail of moderate length and similar to that of the common fallow-deer. The male and female are of different colours; the ground colour of the former is a dark sepia brown above, and white beneath, the head and cheeks being light and sandy-red, and the extremities fulvous; that of the latter reddish-fawn above and white beneath. Two pure white bands cross the throat, one at the junction of the head and neck, and the other at the union of the neck with the chest; the lips and chin are also white; round white spots mark the cheeks, and sometimes the nose in front of the eyes, and similar spots are dispersed irregularly over the hips and thighs, to the amount of a dozen or more on each side, sometimes even forming interrupted lines. The hair is of moderate length, but it is smooth and lies close to the body; the backs of the ears are covered with short brown hair; the tail is black above and white underneath, and the pastern joints are marked behind with two oblong spots of the same colour. In very old males the legs become almost uniformly grey, and at all ages there is a white line running down their inner surface even to the very hoof. All these marks are equally found in the females, but not being so prominently contrasted, on account of the lighter ground colour of this sex, they are not so conspicuous as in the males. There is frequently also a narrow white list along the back, but this is not a constant character in either sex, and is, for the most part, wanting in the females. The young males are of the same colour as the adults, but rather lighter, and the white spots on the hips and thighs more faintly marked.

The boshbok, or bush-goat, as its colonial name implies, resides in the woods, which it never quits but during the bright moonlight nights, or early in the morning, when it comes out to graze on the border of the forest, or to make incursions into the neighbouring gardens and corn-fields. Its voice resembles the barking of a dog, and its deceitful tones sometimes leads the benighted traveller into the most remote and lonely depths of the forest in the vain search after some human habitation, which he is all the time leaving behind him. It is a slow runner, and easily caught when surprised in an open situation, but it keeps close to the woods, through which it penetrates with great ease, running with the horns couched backwards along the sides of the neck, to prevent them from impeding its course by striking against the branches, and having the neck and throat frequently denuded by rubbing against the underwood, as it forces its passage through the thick covers. The species is monogamous, the male and female being always found either alone, or accompanied by one or two kids, but never by adult individuals. It is common enough in Caffraria, and in such parts of the Cape Colony as have sufficient forest to afford it a secure asylum; its flesh makes good venison, that of the breast being particularly esteemed.

20. The Guib (*A. scripta*, Pallas) has the same general characters as the boshbok, and the horns of the male are likewise similar, but it is smaller, lighter, and more delicately formed, and is said to live in society upon the plains, a circumstance which, if it can be relied on, forms a remarkable exception to the habits of the other species of antelopes included in the present group. It measures four feet and a-half from the muzzle to the root of the tail; its height at the shoulder is two feet six inches, and at the croup two feet eight; the horns are eight inches long, the ears five, and the tail six. The horns are straight, a little compressed and twisted spirally upon their axis with two wreaths passing

round them strongly marked at bottom, but obliterated within an inch or two of the points. The general colour is a reddish fawn marked with white lines and spots. The head is unmixed fawn-colour with a dark mark on the forehead and face, white spots in front and beneath each eye, and another on the cheek, at some distance beneath the opening of the ear; the sides of the upper lip and the whole space under the chin are likewise white. The neck is unmixed fawn, deep above and lighter beneath, with a white mark on the breast: the body likewise is deep fawn-colour, with a dorsal line of white and black hair intermixed, and rather longer than those on the rest of the body. From this dorsal line originate eight or ten narrow transverse ribbons of pure white, which pass obliquely down over the ribs and hips, and are crossed on the sides and flanks by one or sometimes two longitudinal bands of the same colour, running from the shoulder to the hips on each side, in a direction parallel to the dorsal line. All these markings are constant in the species and equally common to both sexes; they are at regular distances from one another, and, as Buffon has observed, present the appearance of a set of small harness. A few small, round, white spots are frequently also scattered over the hips and thighs, as in the boshbok, and the interior of the fore-arms, thighs and legs, are likewise of this colour, but the breast, belly, and under parts of the body in general are uniform fulvous brown.

The guib inhabits the west coast of Africa, from Sierra Leone to the banks of the Senegal, from the latter of which localities it was first brought to Europe by the celebrated Adanson. It is said to associate with its own species and to form extensive herds, which reside equally in the forests and on the open plains, particularly in the vicinity of Podor and Goree, where these animals are very numerous. Guib is their name in the Jalloff language. The colours are sometimes subject to a slight variation as far as regards the number of longitudinal and transverse bands on the sides. Colonel Smith has considered this difference specific, and has bestowed the name of *A. phalerata* upon the variety with a single longitudinal line on the flanks, retaining the original name of *A. scripta* for the variety which is marked with two of these lines. This distinction, to say the least of it, is extremely doubtful, and the difference upon which it is founded is in all probability merely accidental.

IX. The ninth group of antelopes includes a number of species characterised by their distinct naked muzzles, horns in the male sex only, distinguished by a single curvature towards the point, more or less strongly marked according to the species, by their large inguinal pores, by the presence of four teats in the females, and by the absence of lachrymal sinuses and knee-brushes. This family is, like the last, exclusively African, the species residing in pairs or small families of five or six individuals in the hilly districts of the south and west coasts of the Continent, generally about the sources of mountain-streams, and among the sedges and reeds on the banks of dried-up river-courses. The qualities of their fur sufficiently indicate these upland and mountainous habitats. The hair is of a woolly texture, fine, close and warm, and in the young animals beautifully frizzled and parted into separate locks. Their legs are robust and powerful, and, though not deficient in point of beauty, they want the light form and graceful action which characterise the generality of the antelope genus.

21. The КОБА, (*A. koba*), called *Grande Vache brune*, or large brown cow, by the French of Senegal, is in size equal to the European stag, being upwards of five feet in length, from the extremity of the muzzle to the root of the tail. The head, measured from between the ears, is fifteen inches long, and the ears themselves nine inches. The horns are twenty inches long, annulated throughout the first three quarters of their length, compressed on the sides, and in full grown animals having a tendency to assume a lyrate form with the point rather blunt and directed forwards. The horns of this animal were originally brought from Senegal by Adanson, and described and figured by Buffon and Daubenton in the twelfth volume of the *Histoire Naturelle*; from that period till very recently nothing further was known of the species, but within the last eighteen months two living specimens, a male and female, have been brought to England, and are now exhibited, the latter at the gardens of the Zoological Society in the Regent's Park, and the former at the Surrey Zoological Gardens. The hair, without being exactly coarse, is long and rough upon every part of the body, standing out from the hide in different directions,

[The Koba, *A. koba*.]

and forming round the neck a kind of rough bristly mane; the ears are long, pointed, and habitually directed forwards, and the tail, broad, and uniformly covered with hair, reaches to the hough, and is without a terminal tuft. The general colour of the body is a dark vinous red on the upper parts and silvery grey beneath, the former being tinged with dark brown along the spine and on the croup, from an intermixture of black hairs. The face and legs are also dark brown, almost approaching to black, the lips, chin, and under side of the tail white, and a longitudinal stripe of the same colour passes over the eyes in the form of eyebrows, and descends for some inches along each side of the face. The feet are marked with faint grey rings immediately above the hoofs, and the ears are internally striated with three longitudinal white lines.

The attitude of the koba when at rest very much resembles that of the nyl-ghau, the feet being gathered close under the body, and the tail pressed in between the hind-legs. In a state of nature its habits are altogether unknown; in confinement it is gentle and timid.

22. The КОБ, (*A. kob*, Erleben,) called *Petite Vache brune*, or little brown cow, by the French settlers on the western coast of Africa, is described as being about the size of the fallow-deer, and similar in colour to the koba, but the animal is only known by the skull and horns brought by Adanson from Senegal. These are pretty large, black, with a single concave curvature directed forwards, approaching one another at the points, and marked on the first two-thirds of their length with seven or eight prominent rings. The head is long and narrow, and without pits for the lachrymal sinus, showing therefore that this organ does not exist; its entire length is nine inches; the length of the horns is thirteen inches on the curves, and their circumference at the base five inches and a half: their distance from one another is eight lines only at the base, five inches in the middle, and two inches and a half at the points.

23. The РЕЙБЕК, (*A. eleotragus*, Schreber,) or reedbuck, so called from its habit of frequenting the reedy banks and beds of dry water-courses, is four feet and a half in length, and two feet nine or ten inches high at the shoulder. The head is ten inches long from the muzzle to the base of the horns, the horns ten inches and a half in a straight line, and thirteen inches along the curves, and the tail eleven inches. The horns are round, annulated at the base, with prominent sharp rings and beautifully striated between, smooth and sharp at the points, and curved forwards with a bold and regular sweep, so as to form almost the segment of a circle. The ears are long and pointed, filled internally with a profusion of whitish hair, and beneath them, on each side of the head, there is a remarkable bald spot of an oval form and shining black colour, which is very characteristic of the species, and readily distinguishes it from all the other antelopes with which it is likely to be confounded. The hair over every part of the neck and body is long and rough, of a uniform dull ashy grey colour, sometimes tinged with red, on the upper parts, and silvery grey on the throat, breast, belly, and interior of the fore-arms and thighs. The

tail is long and remarkably bushy, being covered with a profusion of long woolly hair, for the most part of a white or grey colour, with a narrow brown line running down the middle of the upper side. The females are in all respects similar to the males, excepting that they are without horns, and of rather smaller stature.

[The Reitbok, *A. eleotragus*.]

The reitbok is not found in the immediate vicinity of the Cape, but farther in the interior of the country it is by no means uncommon, living in pairs or small families, and, as already observed, frequenting the reeds and rushy banks of mountain-streams which flow only during the winter season, and are dried up by the summer heats. Sometimes also it is found in woods along the banks of rivers, but always in the neighbourhood of water, and a variety, if not a distinct species, is even said to inhabit the plains. This is of a very deep reddish fawn-colour, and has been described by Afzelius and Hamilton Smith as a distinct species under the denomination of *A. fuvo-rufula*. Excepting in the redder shade of its colour, however, and the name of *Rooie Rheebok*, or red roebuck, by which it is said to be distinguished among the Dutch colonists at the Cape, it does not appear to differ materially from the common variety, and the slight shades of variation which it does present, are most probably the effects of its difference of habitat and other accidental circumstances. The same may be said of the *A. Isabellina*, or cream-coloured antelope of these authors, which does not appear to present any characters sufficiently marked or peculiar to be considered as indicative of a specific distinction.

24. The NAGOR, (*A. redunca*, Pallas,) known only from the description of Adanson and the figure of Buffon, is a species so nearly resembling the reitbok that some naturalists have not hesitated to unite them. It is four feet long from the muzzle to the origin of the tail, two feet four inches high at the shoulder, and two feet six at the croup; the head is nine inches long, the horns five inches and a half, and the ears five inches. The horns have one or two annuli at the base, but are smooth and shining throughout the remainder of their length; they are erect, parallel, and almost straight till within a short distance of the points, where they curve forwards, but not so boldly as in the last species, and this character appears to constitute their chief difference, though it is obvious, from the description, that Mr. Adanson's specimen was a young individual. The colour was uniform fawn or pale red, without any white about the breast or belly, and the hair was long, rough, and undulating, and did not lie smooth or close to the body, characters which all tend to approximate the animal to the reitbok, and more particularly to the variety which is said to inhabit the plains. It is found in the neighbourhood of Goree on the west coast of Africa.

25. The RHEEBOK (*A. capreolus*, Lichtenstein) is nearly five feet in length, and two feet and a half high at the shoulder; the head is six inches long from the muzzle to the root of the horns, the ears and tail, without the hair, about the same length, and the horns of the old male from nine to twelve inches. The head is long, and tapers gra-

dually to the muzzle, which is small, round, and of a black colour; the horns are perfectly smooth and without any appearance of wrinkles or annuli for the two-thirds of their length next the points, but exhibit a few obscure wrinkles at the base; they are remarkably slender, long, straight, parallel, and so sharp at the points, that the Hottentots and Bushmen use them in place of needles and bodkins; the ears also are long, very broad at the base, and attenuated towards the points; the tail long and bushy. The hair, or rather fur, is of a woolly quality, and of a uniform ash colour on the neck, shoulders, sides, croup, and thighs, and white or light grey on the breast, belly, and inner face of the arms and thighs. In young individuals it is beautifully frizzled or curled into distinct locks, and its colour is much clearer than in the adults, which have it straight, loose, and often tinged with a sandy-brown hue on the upper parts of the body. The hair of the legs in the young animal is likewise long and curly like that of a young lamb, but in aged specimens the legs are covered with short close hair of the common quality, and frequently with more or less of a dark brown colour. The hair of the head, face, and cheeks, is always short, crisp, and close; it is brown on the nose, light fawn on the forehead and cheeks, and white about the margins of the lips and underneath the chin; the tail is slaty grey above, and white below, and at the tip; and there is a conspicuous black spot at the angle of the mouth on each side. The hairs individually are obscurely annulated with alternate rings of a grey and light rufous-brown colour, the latter becoming more conspicuous as the animal advances in age, and communicating to the general colour of the fur the light rufous shade already mentioned.

The rheebok is of a lighter and more graceful form than the generality of the other antelopes included in the present section. The body is long and small, the neck particularly so, and the legs slender and well-proportioned. Its pace, consequently, is proportionally swift; it runs with great velocity, keeping close to the ground and moving by long strides, and with a motion so rapid and uniform, that it seems to glide rather than run. The rheeboks live in small families of five or six individuals, consisting of an adult male and three or four females with their young; the males are pugnacious, and compel the young of their own sex to separate themselves from the family as soon as they become adult. Their general residence is on the sides of moderate hills, among stunted trees and underwood, or in the rocky glens and mountain passes, in the vicinity of the little pools of water which remain after the winter torrents have ceased to flow. Wherever such situations are found, the rheebok is not an uncommon animal in South Africa; its flesh is dry and insipid, and esteemed less than that of any other of the numerous Cape antelopes. The female produces but one at a birth, which grows rapidly, and, if caught at an early period, is readily domesticated.

26. *A. landiana*, Desmarest, appears, from the description of this author, to be a species very nearly allied to the rheebok, but differing in the quality and colour of the hair, and in the white marks above the eyebrows. The horns of the male are slender, straight, parallel, very sharp-pointed, and rather shorter than the head; the body is rather large, the legs robust, the ears of moderate size and rounded at the points, the tail twice the length of the ears, covered with hair of the same length throughout, and not descending lower than the hough, the hair of the body long, harsh, and not frizzled. The back, flanks, and sides are uniform clear greyish brown, as are likewise the croup, hips, and thighs, the legs becoming gradually darker brown towards the pateras. The belly, breast, interior of the fore-arms, and thighs, under surface of the tail, throat, chin, lips, and a line over the eyebrows, are white, the colours of the sides and belly being separated on the flanks by an oblique longitudinal line. This animal is said to have the habits as well as the external form of the rheebok, living in small families in the mountainous districts about the Cape of Good Hope, and never by any chance descending into the plains.

X. The tenth group of the genus *antelope* exhibits a character which readily distinguishes it from all those which have preceded, in the possession of maxillary sinuses, or lengthened glands on the cheeks, which distil a dark oily substance, and are sometimes found alone, and at other times accompanied by the presence of lachrymal sinuses. The horns, as we have hitherto found, are confined to the male sex; they are round, short, slightly annulated or

striated at the base, and have a slight curvature backwards or forwards; the head is terminated by a distinct naked muzzle; one species only possesses knee-brushes, and the females have two teats and large inguinal pores. These animals inhabit the moist tropical forests of Africa, and the great islands of the Indian Archipelago, and live in pairs among the underwood.

[The Cambing Outang, *A. Sumatrensis*.]

27. The CAMBING OUTANG, (*A. Sumatrensis*, Desmarest,) first noticed by Mr. Marsden in his *History of Sumatra*, is about four feet and a half in length, and two feet three inches high at the shoulder. The horns are six inches long, very thick at the base and much attenuated, slightly and uniformly curved backwards. The muzzle is distinct and well formed, the lachrymal sinuses open by a small circular aperture, and between them and the muzzle, on each side, is a long linear space, nearly two inches in length by a quarter of an inch broad, naked, and covered with a soft black integument, which represents the maxillary gland, and secretes a particular humour. The ears and tail are of moderate length, the hoofs very large, the limbs short and stout, and the whole form of the animal robust and powerful. The body is thickly covered with a coat of long hair, of a dark brown colour, almost black, excepting along the nape of the neck, on the shoulders, and inside the ears, where it is white, and under the lower jaw, which is of a deep straw-colour. The white hairs of the neck and shoulders are much longer than on other parts of the body, and form a kind of flowing mane; the hair on the head and limbs, on the contrary, is much shorter than elsewhere, the knees are without brushes, and the tail, which is rather shorter than the ears, is covered throughout its whole extent with hair of moderate and equal length, and of the same dark-brown colour as that on the body.

The cambing outang, or wild goat, so called by the Malays, inhabits the hilly forests of Sumatra, and is described by Mr. Marsden as being of a wild character, extremely active and sure-footed, and with much of the habits and character of the common goat and ibex, of which it has the roving fearless eye, and bold undaunted bearing.

28. The FOUR-TUFTED ANTELOPE (*A. quadriscopta*, Hamilton Smith) is known only from Colonel Smith's description and figure of a male specimen formerly exhibited at Exeter Change. The individual, from which Colonel Smith's description was taken, was brought from Senegal.

29. The BUSH ANTELOPE, (*A. silvicultrix*, Afzelius,) called bush-goat by the English residents at Sierra Leone, is about five feet in length from the muzzle to the root of the tail, three feet high at the shoulder, and three feet two inches at the croup; the head, measured from the muzzle to the base of the horns, is upwards of ten inches long; the horns and ears each four inches, and the tail with the hair half a foot. The circumference of the horns at the base is three inches, and their distance at the points five inches; they grow entirely in the direction of the forehead, are pointed, black, shining, nearly straight, with a slight inclination backwards, and diverging gradually towards the points. For about half an inch from the base they are finely

marked with a number of small transverse striae, then covered for about an inch with little depressions and in equalities, and smooth from thence to the points. The ears are situated rather close to the horns; they are about the same length as these organs, broad, open, rounded at the top, and nearly naked; the eye-lids are bordered with thick black lashes, the tail is bushy and pendent, the buttocks nearly naked, the limbs short and slender, the knees unprovided with brushes, and the female furnished with two teats. The hair is, in general, remarkably short, sleek, and shining, of a deep brown colour, rather paler on the neck and flanks, mixed with grey on the thighs, almost yellow on the throat, dun on the cheeks and sides of the jaws, clear brown on the face, nose, and backs of the ears, and chestnut brown on the legs and feet. A tuft of long hair surrounds the base of the horns, and along the middle of the back is a longitudinal line of silvery grey which expands upon the croup, and is provided with hair considerably longer than that on the rest of the body. The tail is black, covered with moderately long hair, and without a terminal tuft.

The proportions of this species are heavy and ungainly, and bear a considerable resemblance to those of the hog-deer of India. The legs are short and slender, and appear disproportioned to the size of the body, which is large and heavy; the head, too, is thick and clumsy, though much attenuated towards the muzzle, the neck short and thick, the croup depressed, and the back very much arched. This species inhabits the west coast of Africa, about Sierra Leone, and the sources of the Pongas and Quia Rivers. It frequents the thickets and underwood of the upland plains and moderate mountain declivities, keeping close to the cover during the day-time, and quitting it only at early dawn for the purpose of feeding in the neighbouring meadows. It is at this time that it is pursued by the hunters, who station themselves on the margin of the woods, and shoot it as it comes out to graze. It is a slow, heavy runner, as might be anticipated from the size and corpulent make of its body, and the shortness of its legs; but it affords excellent venison, and is much sought after on that account. It has long maxillary glands, but no appearance of lachrymal sinuses.

30. The DUICKERBOK (*A. mergens*, Blainville) is of a more active make, and has more graceful proportions than the species last described. In other respects, however, its characters are precisely the same, it has a long maxillary gland on each side of the face, running nearly parallel to the plane of the head, no appearance of lachrymal sinuses, nor brushes on the knees, and the females are provided with two teats. The horns are upright, straight, black, smooth, and very sharp at the points, annulated at the base with a few small rings, and compressed slightly on the sides so as to form a sharp edge in front; but this is not always apparent in old specimens, being perhaps rubbed off or obliterated by friction against the branches and underwood among which the animal resides. They are between four and five inches long, nearly parallel, and point almost imperceptibly forwards. The ears are four inches and a half long, narrow, pointed, and upright; and on the crown of the head, immediately between the roots of the horns and ears, is a remarkable tuft of long black hair, growing from a small centre, and falling round in every direction like the radii of a circle. This is more particularly conspicuous in the females, from the absence of horns in that sex; but besides this black tuft, the whole forehead is covered in both sexes with long hair of a deep red colour, directed upwards, and in the males partly concealing the base of the horns. The body is about four feet in length, and two feet high at the shoulder. It is covered uniformly with rather long but smooth hair of a light brown colour, with a very faint shade of yellow above, and ashy greyish brown beneath. The face and nose, from the eyes to the muzzle, are dark brown; and the legs, over the whole canons before, and half way up behind, are shining black, equally conspicuous at all ages and in both sexes. The tail is six inches long, rather flat, and covered with moderately long black hair, but not tufted.

The duikerbok, or diving-goat, so called by the Dutch of South Africa from its habit of plunging under the bushes in its passage through the woods, instead of leaping over them like the generality of other antelopes, is a common animal in Caffraria and in all parts of the Cape colony which abound in forest and underwood, from the cover of which it seldom ventures, unless occasionally at night to steal into a neighbouring garden. It is found alone or in pairs, makes its way readily among the thickets and low bushes,

and when pursued will from time to time stand up on its hind legs to look round it, then dive under the branches to reappear again at some distance, and thus alternately continuing its flight and standing up at intervals to watch the motions of its pursuers. The peculiar nature of the humour secreted by the maxillary glands of this animal has given origin to a common saying among the Dutch colonists, that it carries the gall-bladder under the eyes. This species is most probably the animal of which the female was long since imperfectly described by Grimm, and which has been admitted into systematic catalogues under the name of *A. Grimmia*. The *A. plox* of Colonel Smith likewise appears to be identical with, or at most a casual variety of the duikerbok, the characters upon which the separation is made being by no means constant, and some of them even of doubtful authenticity.

31. BURCHELL'S ANTELOPE (*A. Burchellii*, Smith) is a species which, from the description of Colonel Smith, though closely resembling the Duikerbok, yet seems to be really different, and to possess appropriate characters which readily distinguish it. The specimen procured by Mr. Burchell during his travels in South Africa was afterwards deposited in the British Museum.

32. The BROAD-EARED ANTELOPE (*A. platous*, H. Smith) is another species of rather doubtful authenticity, described by Colonel Smith from a specimen in the Museum of the Missionary Society, said to have been brought from South Africa.

XI. The eleventh section or group into which we divide this genus begins to exhibit a new character, which we have not found in any of the former divisions, but which is common to all the remaining species of antelopes. It is the presence of horns in the female sex—a character which has a decided influence upon the habits and economy of these animals, not only as it affects the relation which subsists between the sexes by rendering them in a great measure independent of one another, but likewise in modifying the general manners of the species. Those of the present group are further distinguished by having complete naked muzzles, maxillary glands without lachrymal sinuses, inguinal pores, no knee-brushes, and four teats in the females. From the group last described they differ principally by the females being provided with horns, and having four instead of two teats, and by their small size; the present section being composed of the smallest of all horned quadrupeds, except, perhaps, the madoqua, already described. Like the species of the last group, they live singly or in pairs among the bushes or underwood, and rarely venture willingly to quit the thick cover of the woods and forests. As far as is at present known, their habitat is exclusively confined to Africa. There is no group of antelopes in which so much confusion reigns throughout the specific descriptions of naturalists as the present. At least two or three distinct species are known to inhabit the Cape of Good Hope and the west coast of Africa, but their names have been so confused, and their distinctive characters consequently so confounded, that it is now almost a hopeless task to attempt to separate them again, or to attribute to each what properly belongs to it.

33. The GRIMM, (*A. Grimmia*, Desmarest,) the Grimme of MM. F. Cuvier and Desmarest, is certainly a different species from that of Pallas, which is the Kleenebok of the Cape, and likewise from the animal originally described by Dr. Grimm, and which, as we have already observed, appears to be the duikerbok. The original grimm was brought from the Cape of Good Hope, and was described from a female specimen without horns; the animal at present under consideration, and which has rather arbitrarily assumed its name, is an inhabitant of Sierra Leone and the coast of Guinea, and is probably the real Guevi of Adanson's *Travels in Senegal*. A male of this species formerly lived in the menagerie at the Jardin des Plantes at Paris, and was the subject of the foregoing description: it was brought from the coast of Guinea, and showed an extreme timidity in confinement; its habits in a state of nature are unknown.

34. The KLEENEBOK, (*A. perpusilla*, H. Smith,) very improperly called *guevi* by M. Desmarest, is about a foot high at the shoulder; the horns an inch and a half long in the male, three-quarters of an inch in the female, and the tail about two inches and a half. The horns are small, erect, black, slightly inclined backwards and towards one another at the points, and very sharp, with seven or eight minute annuli at the base; the ears about the same length as the horns, perfectly round at the tips, and nearly naked

[The Kleenebok, *A. perpusilla*.]

within; the head is long and pointed; the maxillary glands not parallel to the plane of the face, but nearly in the same line with the greater axis of the orbits, or rather in lines parallel to them; the forehead and nose are brown, bordered on each side by a narrow line of a sandy-red colour passing from the root of the horns down to the muzzle; the upper parts of the body are of a uniform dark slaty-brown colour; all the inferior parts, including the region under the chin, the breast, belly, interior of the fore-arms and thighs, and under-surface of the tail, ashy-grey, inclining to white in some specimens, particularly in young individuals; the legs are reddish-brown, and the hoofs small, narrow, and pointed.

This species, called by the Dutch colonists of the Cape *Kleenebok*, *Kleene blauw-bok*, *Blauwbokje*, all signifying little goat or little blue goat, inhabits South Africa, and lives singly or in pairs among the bushes. It is extremely active, and of a mild and timid disposition, but from the nature of the thick bushes in which it resides is not often seen even in those districts where it abounds most plentifully. It is said to exhibit considerable sagacity in eluding pursuit, and when domesticated soon becomes familiar and learns to distinguish those about it and to answer to its name. This species is also the *A. cerulea* of Colonel Smith and the *A. pygmæa* of M. Desmarest, who confounds it with the *guevi* of Senegal.

35. MAXWELL'S ANTELOPE (*A. Maxwellii*, H. Smith) is a species described only by Colonel Smith. The female specimen, from which Colonel Smith's description was taken, lived two years in England, and produced a kid in confinement.

36. The GUEVI, (*A. pygmæa*, H. Smith,) said to be the smallest, and certainly the least known, of the whole antelope genus, was first mentioned by Adanson, as an inhabitant of Senegal, and the name has since been arbitrarily applied by different zoologists to two or three distinct, though ill-determined species. It is the royal antelope of Pennant; and though the female is described, on the authority of Bosman, as being destitute of horns, it is probable, from the other characters attributed to the species, that this fact is not correct, but arises from want of careful examination, and that the animal really belongs to the present section. The horns of the male are described as short, straight, black, polished, and not quite two inches long; the ears broad and round; the legs not thicker than a goose-quill; the height scarcely nine inches, and the colour a uniform reddish-brown. Notwithstanding its very diminutive size, it is said that the guevi will bound with ease over a wall twelve feet high. It is readily domesticated, but too tender to endure the cold of Europe. Adanson mentions a still smaller species or variety of guevi, which is said to inhabit the province of Kaor, on the northern banks of the Gambia, and to be not much larger than a good Norway rat. It is upon this animal that Buffon appears to have founded his *Chevroliane de Guinée*, and Linnaeus his *Moschus pygmæus*.

XII. We have now arrived at a group of antelopes which have been celebrated, from the most remote antiquity, for the beauty of their external forms, the grace and elegance of

their movements, and the mildness and gentleness of their manners. Of this group, the common gazelle or Barbary antelope may be considered as the typical representative; but this animal is itself so closely related to two or three neighbouring species, that it has been found very difficult to distinguish them by characters at once sufficiently marked and constant. The group, however, is collectively characterised by prominent and peculiar traits which are in a great measure appropriate, and which definitely separate it from all other sections of the antelope genus. The principal of these consist in having the horns common to both sexes, more or less compressed on the sides, annulated nearly to the points, and lyrate, or with a double curvature, first backwards at the base, and afterwards pointing gently and moderately forwards, in the males; short, round, smooth, straight, and upright till within an inch of the points, which turn abruptly inwards towards one another, in the females; in the form of the upper lip, which is hairy and attenuated like that of the goat; in the possession of distinct suborbital sinuses without any appearance of the maxillary glands which characterise the last two groups; in the presence of very large inguinal pores, and, in most species, brushes on the knees; and in the females being provided with four mammae or teats. The species belonging to this division are, for the most part, gregarious, living in large flocks on the open plains, karroos, and steppes of Africa and Asia, feeding upon the aromatic herbs and saline plants of the desert, and uniting for mutual defence against the attacks of wild beasts.

[The Gazelle, *A. dorcas*, Pallas.]

37. The GAZELLE (*A. dorcas*, Pallas) is three feet six inches in length, one foot nine inches and a half high at the shoulder, and one foot ten and a half at the croup; the head is six inches long, the horns nine and a half, the ears four and three-quarters, and the tail, with its terminating tuft, eight inches. The horns of the old male are surrounded by thirteen or fourteen prominent rings, complete and close together at the base, more distant, oblique and interrupted behind towards the points, the last inch or inch and a half alone being smooth and free from annuli; they rise almost immediately above the orbits, are black, almost cylindrical, at first bent gently backwards, and finally forwards; in the females they are much smaller, seldom exceeding the ears in length, surrounded at the base with a few obscure wrinkles, smooth and polished throughout the rest of their extent, straight to near the tips, and pointing inwards. This is the character of the *corinne* of Buffon, which is now considered by the best zoologists to be nothing more than the female either of this or the following species, and not itself a distinct species, as was formerly supposed. The ears of the gazelle are long, narrow, and pointed, the eyes large, mild, and black, and the tail round, furnished on its upper surface only with an upright ridge of stiff black hair, and terminated by a little tuft of the same colour; the size of the body is about equal to that of the roebuck, but the legs are considerably longer, and the whole form lighter and more elegant; the face and cheeks are reddish fawn-colour, and the nose has a broad

mark of a dark brown colour, approaching to black, on each side of the face, passing over the eyes from the horns down to the nose, there is a broad white stripe, and beneath this, from the anterior canthus of the eye, a narrower dark stripe, parallel to it and separating it from the fawn-colour of the cheeks; the hind part of the head, the back of the ears, neck, shoulders, back, sides, and croup, are fulvous, of different shades according to the age of the individual; all the under parts are white, and this colour is separated from the fulvous of the sides by a broad dark-brown longitudinal band on the flanks; the knees are furnished with brushes of dark hair, and the ears are filled internally with long white hair arranged in three longitudinal stræ.

The gazelle is found in Egypt, Barbary, and some say also in Asia Minor; but it is very questionable whether the animal of the Levant does not really belong to a different species, to the *Antelope Arabica*, or perhaps to the *Antelope subgutturosa*. It lives in large troops upon the borders of the Tell, or cultivated country, and the Sahara, or desert; when pursued, flies to some distance, then stops to gaze a moment at the hunters, and again renews its flight. The flock, when attacked collectively, disperse in all directions, but soon reunite, and, when brought to bay, defend themselves with courage and obstinacy, uniting in a close circle, with the females and fawns in the centre, and presenting their horns at all points to their enemies; yet, notwithstanding their courage, they are the common prey of the lion and panther, and are hunted with great perseverance by the Arabs and Bedowens of the desert. When taken young, they are easily domesticated, and soon become familiar. This animal is frequently cut upon the monuments of Egypt and Nubia.

38. The KEVEL (*A. kevela*, Pallas) is still very imperfectly distinguished from the gazelle, but appears to be in reality a different species, characterised principally by the compression of its horns, their being provided in the adult male with a greater number of annuli, and bending forwards with a more bold and sudden curvature at the points. The habitat also of these two animals is different, the kevel being found only on the opposite side of the great African desert to that inhabited by the dorcas; and this is itself a strong argument in favour of those who maintain their specific difference, though it must be admitted that they require a careful examination and comparison. This species is found in Senegal, where, according to the report of Adamson, kevel is its name among the natives. It resides in extensive flocks on the open stony plains, and is said to be in all respects similar to the gazelle in its manners and habits.

39. The AHU (*A. subgutturosa*, Guldénstædt) is likewise a species which requires to be re-examined, and carefully compared with the gazelle and kevel, not that there is any reasonable doubt as to its actual existence, but because its characters have not been sufficiently distinguished from those of the conterminous species, which has given rise to no small confusion and fluctuation of opinion upon this part of our subject. The ahū inhabits all the central parts of Asia, Persia, Dauria, the country around lake Baikal, and from the eastern limits of Great Bucharia to the shores of the Hellespont. It associates with its own species in extensive flocks, frequents the open uncovered plains and naked hills of moderate elevation, and feeds principally upon the *absinthium Ponticum*. The flesh is much esteemed, and of an agreeable taste.

40. The KALSCHEPEE, (*A. Bennettii*, Sykes,) described by Colonel Sykes in the first part of the *Proceedings of the Zoological Society*, is an elegant species closely allied to the dorcas in all its most prominent characters, but higher on the limbs, and considerably different in its habits. This species seems to be the *antelope cora* of Colonel Smith.

The kalschepee, or black-tail, so called by the Mahrattas, on account of the deep black colour of that organ, and distinguished by the name of the goat antelope by the Europeans, is found on the rocky hills of the Deccan, and, according to the report of Colonel Sykes, differs from most other antelopes of the present section in not being gregarious, there being rarely more than three or four found together in the same company, and not unfrequently a solitary individual.

41. The ARIEL ANTELOPE, (*A. Arabica*, Hemprich and Ehrenberg,) so called by the Arabs on account of its light, elegant, and graceful form. The size and proportions of this animal are similar to those of the gazelle and other

species already described in the present section; the colour, however, is considerably deeper and darker than that of the common dorcas.

This species inhabits Arabia, and was found on the stony hills along the eastern shore of the Red Sea, by the travellers Hemprich and Ehrenberg, whose recent journey in northern Africa and western Asia has been productive of such a vast collection of new and interesting zoological riches.

[A. Scemmeringii.]

42. *A. SCEMMERINGII*, (Cretzschmar,) one of the most beautiful antelopes of this section, was discovered by Rüppel, (during his journey through the northern provinces of Abyssinia,) and is described by Cretzschmar in the zoological part of that traveller's works. It is considerably larger than the species hitherto described in the present group. The horns are irregularly lyrate, bending boldly outwards towards the points, and then suddenly turning inwards towards one another, with a very sharp and well-defined curve: annulated with fifteen or sixteen prominent and complete rings which reach from the base to the inward curvature within about two inches and a quarter of the points. The colour of all the upper parts of the body, the neck, shoulders, back, croup, sides and outward faces of the fore-arms and thighs, is a beautiful clear isabel or yellowish dun, the hair being extremely short, and appearing almost as if it had been clipped or shorn. It does not lie close and smooth upon the hide, nor does it all follow the same direction, as in the generality of animals, but is disposed in innumerable small waves, pointing in different directions, as if it had been regularly shaded and parted on each side, and appearing glossy or glazed along their ridges with a shining dun shade, more or less intense according to the light in which it is observed. All the under parts of the body are of the most pure and brilliant white, and a large disk of the same colour surrounds the tail and passes over the rump and croup. The white of the belly also is separated from the yellowish dun of the sides, immediately, without being shaded off. The tail is small and slender, nearly naked at the root, and furnished at the extremity with a tuft of mixed brown and grey hairs. The outsides of the legs are very pale fawn-colour, the insides white, and the knee-brushes white and fawn mixed. The ears are pretty long and brown, with a narrow black border surrounding their outer edge. The face is dark brown in some specimens, and pure black in others, uniform towards the end of the nose, but curiously mixed with wavy red on the forehead: on each side of this a broad white band passes from the root of the horns over the eyes to the nose, and there is an indication of a small black one from the anterior angle of the eye to the corner of the mouth, separating this white band from the cheeks and sides of the lower jaw, which are uniform fawn-colour. The horns of the female have nearly the same curvature as those of the male, and are fully as long, but they are much more slender, and have not such prominent annuli. This is the only external difference observable between the sexes.

This antelope frequents hills of moderate ascent and elevation in the eastern provinces of Abyssinia, and is said to live in pairs, and not to unite into large flocks like the gazelle and kewel.

43. The *SPRINGBOK*, (*A. euchore*, Forster,) called likewise *Pronkbock*, or Showy goat, by the Dutch of South Africa, and *Tesbé* by the Hottentots, is perhaps the most graceful in its proportions, and beautifully varied in its colours, of all the antelope tribe. Imagination cannot conceive a quadruped more light and airy in form, more delicate in its proportions, or whose movements are executed with more natural ease and grace, than the springbok, or, as the English colonists now universally denominate it, springbuck. In point of size it is nearly a third larger than the dorcas. The horns of the springbuck are rather irregularly lyrate, like those of the species last described: they are round, black, annulated very regularly till within a short distance of the points, spreading first backwards and widely outwards, and finally turning inwards, and with an almost imperceptible twist on their own axis backwards. The hair is long on the upper parts of the body, particularly on the back and croup, but smooth, sleek, and shining: it is of a beautiful light cinnamon-colour on the shoulders, neck, back, sides, and thighs, and of a pure snowy white on the breast, belly, and inner face of the limbs, these two colours being separated on the flanks by a broad longitudinal band of a deep vinous red colour, larger and more distinct than in any other species of antelope. The whole head, face, cheeks, and chin are white, with a broad brown band on each side from the eyes to the corners of the mouth, and a mark of the same colour on the centre of the face, commencing in a narrow point or the muzzle, and enlarging as it proceeds upwards, till it joins the reddish fawn-colour of the body on the crown of the head. The eyes are large, lively, and of a brown colour: the ears long, small, and cylindrical at the root, then widening in the middle, and ending in an attenuated point. The neck is long, slender, and slightly compressed on the sides, the hoofs are small, black, and triangular, the legs remarkably long and slender, and the tail small, round, and naked, except a ridge of stiff black hair which fringes it along the upper surface, and forms a small tuft at the extremity. But the most remarkable and distinctive character of this species consists in two longitudinal foldings or duplications of the skin on the croup, which commence above the loins, or about the middle of the back, and run in a straight line from thence to the tail. The interior of these folds is lined with long hair of nine or ten inches in length, and of the most brilliant and snowy whiteness; they are likewise under the complete command of the animal's volition, and are opened and shut at pleasure. When closed, which they always are when the animal is at rest, their lips form a narrow line along the top of the loins and croup, which, being covered by the long cinnamon-red hair of the back and hips, is scarcely distinguishable, or only as a narrow white streak; but when the animal leaps or runs, these folds are expanded, and form a broad circular mark of the purest white, which extends over the whole croup and hips, and produces a most remarkable and pleasing effect.

The springbuck is so called from its remarkable habit of jumping almost perpendicularly upwards, apparently without any other motive than for its own amusement. It resides, in almost innumerable flocks, on the dry arid plains and karroos of the interior of South Africa, seldom approaching the inhabited districts of the colony, unless in seasons of peculiar drought, when the pools and pastures of the interior are dried and burnt up by the excessive heat, and these animals are compelled to migrate in search of a more abundant supply. On these occasions they are said to unite into flocks which often consist of from ten to fifty thousand individuals, spreading over the face of the whole country like a swarm of locusts, devouring every vegetable substance that they meet with, and scarcely deviating from their direct path to avoid the men and dogs which endeavour to turn them into another direction. So great are their numbers, that those which happen to get into the rear of the troop are lean and half starved before the migration is concluded, from the advanced ranks cropping the scanty pastures almost bare, and thus leaving them nearly destitute of food; but when the journey is concluded, and the troop begins to retrace its steps northwards, those which formed the van during the advance are necessarily in the rear returning, soon lose their plump condition, and are in their turn subjected to want

and starvation. During these migrations they are closely followed by lions, panthers, hyænas, and wild dogs, which destroy great numbers of them. There is perhaps no object in nature finer than a flock of these beautiful antelopes enlivening the dreary brown karroos of South Africa with their graceful motions, now leaping perpendicularly upwards to the height of six or seven feet, displaying at the same time the snowy white marks on their croups, and anon flying over the desert with the speed of a whirlwind. It is only when disturbed, or otherwise excited, that they make those extraordinary springs from which they have derived their name; nor do they ever display the white mark on the rump except on these occasions. They are said to be particularly affected by the change of the weather, and are observed to leap more than usual before the setting in of the south wind, which, at the Cape of Good Hope, generally betokens stormy weather, and is always violent and tempestuous. When taken young, the springbuck is easily tamed, and soon displays all the petulance and familiarity of the common goat, butting at every stranger that approaches it, and warding off stones or other objects thrown at it with its horns.

44. The **BLESSBOK**, (*A. pygarga*, Pallas,) also a South African species, is considerably the largest animal belonging to the present group: it is, in point of size, superior to the stag of Europe, measuring, when full grown, five feet and a half in length, and rather better than three feet and a half in height at the shoulder. The horns are sixteen inches long, large, regularly lyrate, and of the same form in both sexes, those of the males being only thicker and heavier than those of the females. They are round, annulated with eleven or twelve prominent rings which reach to within a couple of inches of the points, rather close at the base, regularly but moderately divergent, and five inches separate at the tips. The ears are seven inches in length, erect, pointed, and cylindrical, reddish-fawn colour on the back and white within, with the usual longitudinal stria. The colours of the head and body are most singularly disposed; the whole animal appears as if it had been artificially painted with different shades laid on in separate masses. The head and neck are of a brilliant brownish-bay, so deep as to resemble the colour of arterial blood; this is particularly visible upon the cheeks and about the root of the horns, from the central point between which descends a narrow stripe of the purest white as far as the orbits, immediately above which it expands and covers the whole face and nose down to the muzzle, forming a broad mark, or, as it is called in horses, a blaze, and giving origin to the name of *blessbok* or *blazebuck*, by which this species is known among the Cape colonists. The back is of a brownish-bay, thickly overlaid, or, as it were, glazed or japanned with dull purplish-white, and there is a very broad purplish-brown band on the flanks passing from the fore-arm backwards, and extending obliquely over the outer face of the thighs. The breast, belly, and interior of the fore-arms and thighs are white, and this colour also shows itself on the posterior face of the hips and thighs, and passes in a small crescent over the rear of the croup, forming a white disk around the tail, and giving origin to the specific name of *pygarga*, which has been rather arbitrarily bestowed upon this animal, the real *pygarga* of the ancients being certainly a different species, and an inhabitant of northern Africa. The tail is long and switched, nearly naked at the root, and terminated by a tuft of very long black hair; the trunk alone is seven inches in length, and the terminal tuft four inches more, making the tail altogether about a foot long. The knees are without brushes, but M. Desmarest, and indeed the generality of naturalists who have described it, are mistaken in supposing this species to be without lachrymal sinuses.

This splendid animal, which is likewise called *bontebok* or painted goat, by the Dutch, was formerly very common in the colony of the Cape, and is still found in the district of Zwillingdam, east of Cape Town, but it has long ceased to abound in the enormous multitudes which old travellers mention to have spread over the plains like a troop of springboks. The young are at first of a brownish-red colour on the body, partially glazed, as in the adults; but what is most remarkable of all is, that the face, instead of being white as in the grown animal, is of a very deep brownish-black colour, slightly mixed with scattered grey hairs. This singular mark of monage, which could not have been well anticipated, has given rise to the very natural and pardonable error of Mr. Woods, who, in the 16th No. of the *Zoological*

Journal, has described the young *blessbok* as a distinct species, under the name of *A. personata*. The mistake is pointed out in Smuts's *Dissertatio Zoologica*.

XIII. The thirteenth section of the genus *Antelope* contains a small but interesting group of these animals, which Mr. Bennett has formed and characterised in the first volume of the *Transactions of the Zoological Society*. It comprehends the species which Pliny has mentioned under the name of *dama*, and is distinguished from the last section only by the character of the horns, which are larger, thicker, and have much bolder curvatures, turning first almost horizontally towards the rear, and then suddenly forwards so as to form a hook towards the front almost as complete as that of the chamois is towards the rear. The legs are remarkably long, the neck long and slender, and there is a white spot on the throat of all the species. In other respects the characters are precisely the same as those of the species belonging to the twelfth section.

[The Mhorr, *A. mhorr*.]

45. The **MHORR** (*A. mhorr*, Bennett) is four feet two inches long from the nose to the origin of the tail, two feet six inches high at the shoulder, and two feet eight inches at the croup; the length of the head from the nose to the root of the horn is seven inches; that of the horn nine inches and a half on the curve, and seven and a half in a straight line; and that of the tail seven inches without the terminal tuft. The hair of the body is sleek and of moderate length; on the head and face it is very short and close, except about the root of the horns, where it is slightly tufted; the hair of the limbs is also short, except the tufts below the knees, which are long and consist of a mixture of dark brown and grey hairs. The horns are thick at the base, and annulated with eleven or twelve prominent and complete rings, which occupy about two-thirds of their entire length; they are round, smooth, and attenuated towards the tips, which point directly forwards, and are but moderately sharp. The ears are narrow, erect, and pointed; the eyes large, dark, and lively; and the tail long, naked at the base, and furnished at the extremity with a tuft of long black hair. The colour of all the upper parts of the body, of the neck, back, shoulders, sides, fore-arms and thighs, as well as of the whole throat except a square spot on the larynx, is a deep brownish-red, and a narrow stripe of the same colour is continued down the outer face of the legs, both anterior and posterior, from the shoulders and thighs respectively to the hoofs and pasterns: the belly, buttocks, posterior face of the thighs and inner face of the extremities are pure white, as well as the spot on the larynx above referred to; and this colour, after spreading round the entire region of the tail, is continued forwards on the hip in a pointed stripe on each side, about half way between the croup and the knee joint, and reaching nearly over the whole hip. It contrasts strongly with the surrounding colour, and has a very singular effect. There is no dark band on the flanks, the light colours of the under parts being abruptly separated from the darker shade above without any blending or intermediate colour. The head and cheeks are light fawn-colour, intermixed, in front of the horns, with dark brown and grey hairs, and marked

below the opening of the suborbital sinuses with a small dark spot representing the black band which passes in the species of the last division from the anterior canthus of the eye to the corner of the mouth: the whole line of the nose and chaffron are likewise dark brown, mixed with grey in old specimens, and the back of the ears is fawn-coloured, tipped with black.

Two males of this beautiful species were sent from Mogadore to the Zoological Society, and lived for some time in the gardens of the Regent's Park. The species is not found in the empire of Morocco, but individuals are occasionally brought from the opposite confines of the Desert; the animal is much sought after by the Arabs on account of producing the bezoar stones so highly valued in eastern medicine. These stones are commonly called in Morocco, Baid-el-Mhor, mhor's eggs.

46. The NANGUER (*A. dama*, Pallas). This species was originally described and figured by Buffon from materials brought by Adanson from Senegal; since that time the animal has not been seen by any naturalist, and as the description of Buffon is imperfect, some reasonable doubt may be entertained whether it be not in reality the young of the mhor.

47. The ADDRA (*A. ruficollis*, H. Smith) is a beautiful species of eastern Africa, discovered on the barren wastes of Nubia by Rüppel, and in Sennaar and Dongola by Hemprich and Ehrenberg. The whole length of this species is five feet four inches, its height at the shoulder three feet; the length of the head is eight inches, that of the horns twelve inches and a half, and that of the tail nine inches. The horns are precisely similar to those of the mhor already described, as are likewise the general form and proportions of the body. This species is gregarious, and resides in flocks on the desert between Nubia, Dongola, and Kordofan.

XIV. The fourteenth group of antelopes is distinguished by having small horns perfectly smooth and black, springing immediately above the orbits, almost perpendicular to the plane of the face, and straight for the first two-thirds of their length, then bent abruptly backwards so as to form a perfect hook, very sharp at the points, and common to both sexes. The lips are hairy and attenuated; there is no lachrymal sinus nor maxillary gland, but a small fold or opening of the skin of the occiput nearly at the root of each horn, (which, however, appears not to be provided with a secreting gland like these organs,) is a character peculiar to the present group, and, as already observed, may have given rise to the opinion of the antients, that goats breathed through their ears. The form of the horns and the possession of inguinal pores are the only characters which the species included in this group possesses in common with the antelope tribes; all its other characters approximate it to the goats, as well as its habits and mode of life, and it appears in fact to form the natural link which connects these two genera. The knees are without brushes, and the females provided with two teats. There is but a single species,

[The Chamois, *A. rupicapra*.]

48. The CHAMOIS, (*A. rupicapra*, Pallas,) the only animal of western Europe that partakes in any degree of the characters of the antelopes. The horns of this species have been sufficiently described above; they are seldom more than six or seven inches long, and are nearly parallel throughout their whole extent. The entire length of the body is about three feet three inches, that of the head to the root of the horns six inches, that of the ears four inches, of the tail three inches and a quarter, and the height at the shoulders rather better than two feet. The whole body is covered with long hair, hanging down over the sides, of a deep brown colour in winter, and brownish-fawn colour in summer, being in spring slightly mixed with grey: the head is of a very pale yellow or straw colour, with a dark brown band on each side passing from the root of the ear to the corners of the mouth, and encircling the eyes and base of the horns; the tail is short and black, and the edges of the hips and interior of the thighs and ears alone white. The face is straight as in the goat, the ears small, erect, and pointed, and the chin without a beard. In old individuals, particularly during the severe colds of winter, the cheeks, chin, and throat turn white, and the breast and belly are at all times of a light silvery brown or yellow. Underneath the external covering there is a short thick coat of fine wool, which lies close to the skin, and protects the animal from the rigours of the cold mountain regions which it inhabits. The colours of both sexes are the same, but the females are rather smaller than the males, and have horns less abruptly hooked backwards. They go five months with young, and kid in March or April, producing one or very rarely two at a birth, which they suckle till the October following. The young are at first of a uniform deep yellowish brown, with the lower jaw, sides of the head and throat white, and the same dark bands through the eyes as in the adults, only not extending so far back on the head.

The chamois, like the ibex, inhabits the loftiest chains of the primitive mountain ridges, and displays all the vivacity, restlessness and agility of the common goat. It is extremely impatient of heat, and during summer is only to be found on the tops of the highest mountains, or in deep glens where the snow lies throughout the year: in winter, however, it descends to the lower ridges, and it is then only that the hunters can pursue it with any hope of success. Its senses of sight and smell are remarkably acute; it scents a man at the distance of half a league, and displays the greatest restlessness and alarm till it obtains a sight of the object of its terror, leaping upon the highest rocks at hand in order to command a more extensive prospect, and uttering a suppressed whistle or hissing sound, being all the time in a state of the greatest agitation; but no sooner does he appear in sight than it flies with the utmost speed, scaling rocks which few other animals could attempt, and, if not intercepted by stratagem, soon leaving its pursuers far behind. The usual and most successful mode of hunting the chamois is therefore for a party of hunters to unite, and surround some mountain glen which they are previously known to frequent for the purpose of lying on the fresh snow during the day-time; towards this point the hunters advance simultaneously, and the animals, of course scenting those which come down the wind, retire in an opposite direction and are intercepted by another party. The food of the chamois consists of mountain herbs, flowers, and the tender shoots of trees and shrubs; it seldom drinks. Nothing can be more admirable than the agility with which it ascends and descends rocks apparently perpendicular. It does not descend at a single bound nor in a vertical direction, but by projecting itself obliquely or diagonally forwards, striking the face of the rock three or four times with its feet for the purpose of renewing its force, or directing it more steadily to the point it aims at; and in this manner it will descend a perpendicular rock of twenty or thirty feet in height, without the smallest projection upon which it could rest its feet. This animal is extremely partial to salt, and many stones are met with in the Alps hollowed by the continual licking of the chamois on account of the saltpetre with which they abound. The species is found in all the high mountain chains of Europe and western Asia, in the Pyrenees, the Alps, the Carpathian and Grecian mountains, the chains of Caucasus and Taurus, and perhaps in other situations.

XV. We have now arrived at a group which departs considerably in form and proportions from the symmetry and grace of the antelope tribe in general, assuming something of the weighty, solid make and massive proportions of the

bovine genus, which it likewise begins to approach in its zoological characters. The horns are common to both sexes, long, erect, and annulated, straight, or with a single curvature backwards, or in one species twisted into a beautiful spiral of two or three turns; the head is terminated by a half-formed muzzle, considerably more developed than in the sheep or goat, but not so completely as in the ox or stag; there are no suborbital sinuses (except, perhaps, in one species); neither are there any knee-brushes or inguinal pores, and the females are provided with four teats. The species belonging to this division are all natives of Africa, and perhaps one may extend across the southern shores of Arabia as far as the borders of Persia, but the fact is extremely doubtful.

49. The ADDAX (*A. addax*, Lichtenstein) is mentioned by Pliny under the name of *strepticerus*, which, says he, the Africans call *addax*, (or it may be, *addas*, for the accusative *addacem* is the word used in the passage referred to, and it may be derived from either of these forms in the nominative.) From the time of Pliny the only information which we had about this animal till a very recent period was derived from a figure and description of the skull and horns sent by our celebrated countryman Caius to his friend Gesner, and inserted in the great work of that early naturalist: the recent travellers, Rüppel and Hemprich, and Ehrenberg, have lately rediscovered this species, and what is singular enough, under the antient African name ascribed to it by Pliny, the Arabs still denominating it *akasch*, *akas*, or *addas*, with the addition of the syllable *abu* (father), which they bestow upon many other animals, as *abu-Hannis* (father John) for the ibis, &c.

The length of the full grown addax is six feet from the muzzle to the root of the tail, and its height at the shoulder three feet; the horns, measured along the curves, are three feet long, the ears six inches, and the tail, with its terminating tuft, one foot. The animal is therefore about the size of a large ass, of which it has likewise much of the make and proportions, the heavy head, thick neck and legs, and switch tail. The horns are round, rather slender in proportion to their length, twisted outwards and describing two turns of a wide spiral, annulated to within five or six inches of the points, which are smooth and sharp; the form of the horns of the female does not differ from that of the male, but in the young they are almost straight. The ears are pretty long and proportionally broader than in most of the smaller antelopes, and the tail reaches almost to the hough and is terminated by a switch of long, coarse grey hair. The whole head and neck, both above and below, are of a deep reddish-brown colour, except a transverse mark of pure white across the lower part of the forehead, between the orbits, which expands on the cheeks and half surrounds the eyes; a patch of black curly hair surrounds the root of the horns, and there is a scanty beard of the same colour on the larynx; all the rest of the animal, including the entire body from the neck backwards, as well as the legs and tail, are greyish white; the hoofs are black, and remarkably broad, to enable the animal to pass more easily over the fine and loose sands of the deserts in which it resides.

These animals live in pairs on the sandy deserts of central Africa, and appear to extend over the greater part of the continent. Hemprich and Ehrenberg found them in Dongola; and a pair of horns were brought from Bornou by Denham and Clapperton, and deposited in the British Museum. [See the article ADDAX.]

50. The ABU-HARB (*A. leucoryx*, Pallas) is, perhaps, the most celebrated of all the antelope genus, being the species which is generally supposed to have given rise to the fabulous unicorn of the antients. It is, indeed, properly speaking, the *oryx* of antient writers, but modern authors have followed the example of Pallas in bestowing that name upon a species of southern Africa with which it is impossible that the antients could have been acquainted, whilst the present species has received the name of *leucoryx*, from an epithet bestowed upon it by Ælian on account of its white colour. The dimensions of this animal are very little less than those of the addax. The horns are at first directed in the plane of the forehead, and have a single gradual and moderate curvature throughout their whole course, forming, as it were, the segments of a very large circle; they are small in proportion to their great length, annulated about half way up, gradually attenuated, and very sharp at the points. The ears are long, erect, and pointed, and the tail is terminated by a very copiously furnished tuft of

long hair of a mixed black and grey colour, which reaches below the houghs. The hair on the head, body, and extremities, is universally short, and lies smoothly along the hide, except upon the ridge of the back, where it is rather longer and reversed, or turned towards the head in a direction contrary to that on the other parts of the body, and forming a short reversed mane from the middle of the back to the occiput. The head is white, with a brown mark descending perpendicularly from each orbit, and expanding over the cheek, and a similar stripe passing down the centre of the face from the horns to the muzzle; the whole neck also, on the throat as well as on the upper part, is of a uniform rusty brown colour, but, with these exceptions, all the rest of the body, as well as the legs and tail, are milk white.

This species is frequently represented on the monuments of Egypt and Nubia, and particularly in the inner chamber of the great pyramid at Memphis, where a whole group of these animals is represented, some being driven or pushed forwards, and others led by the horns or by a cord about the neck, apparently by way of tribute from some subject or conquered nation. With one exception, these representations are invariably in profile, so that only one horn is seen. The present species is gregarious, and lives in large herds in Sennaar and Kordofan, feeding principally upon different species of acacias.

[The Al gazel, *A. gazella*.]

51. The ALGAZEL, (*A. gazella*, Pallas,) described and figured first by Prosper Alpinus, and more recently by M. F. Cuvier, is so nearly related to the last species, that we should have no hesitation in considering it as absolutely the same, did not this eminent zoologist expressly inform us that his al gazel was furnished with lachrymal sinuses, which certainly no other species of the present group possesses. The specimen described by M. Cuvier was sent from Senegal, and lived for some time in the menagerie of the Jardin des Plantes. As this is at present the most obscure species of the group, we have copied the engraving of M. Cuvier, to give the reader the opportunity of comparing it with the beautiful engravings of the former species published in the works of Lichtenstein, Rüppel and Hemprich, and Ehrenberg. Though the specimen described by M. Cuvier was obtained from Senegal, we are assured that the animal is unknown, or at least very rare, in that country, and only brought occasionally from a distant part of the interior.

52. The GEMSBOK (*A. oryx*, Pallas) is in all respects a very distinct and marked species. It is a heavy, stout animal, about five feet in length, and three feet two inches high at the shoulder; the length of the horns is from two feet to two and a half, that of the ears seven inches, and that of the tail thirteen or fourteen. The horns are almost perfectly straight, very little divergent, and situated in the plane of the forehead; they are obscurely annulated for half their length, black, and blunt in the male, but very sharp pointed in the female. The ears are large and pointed, and the tail pretty uniformly covered with long black hair, forming

a large switch. The general colour of the body is dark rusty-iron grey on the upper parts, and white on the under, the two being separated on the flanks by a broad longitudinal band of dark brown or black; and the hair of the back and neck reversed, as in the two species last described. The head is white, marked with two transverse bands of deep black, rising from the root of the horns and passing down the face, then encircling the eye, and uniting under the lower jaw with those of the opposite side. From this point, a black band passes down the throat upon the chest, where it divides into four, one pair of which pass along the flanks and divide the colours of the upper and under parts of the body, the other pair encircles the fore-arms; the thighs are likewise black, whilst all the rest of the limbs is white, except a black mark on the canons. On the upper surface, the black line passes down the neck and back, and expands into a broad disk on the rump. These colours are all boldly separated from one another, and the harshness of their contrast produces a very singular effect upon the appearance of this animal.

The oryx inhabits the karroos of South Africa: it is never found in the woods, but keeps on the open plains, and lives in pairs or small families of four or five individuals. It is extremely dangerous to approach when wounded, if not completely disabled, making vigorous use of its long powerful horns, and it is said being not unfrequently the first to commence the assault. We are even assured that the lion himself is afraid to attack this powerful and courageous animal, and that sometimes, when pressed by famine he has ventured to do so, he has been beaten off with disgrace, or even paid for his temerity with his life.

XVI. The sixteenth group differs from that which we have just described by having the muzzle more completely formed, but in all other respects the characters are precisely the same, at least as far as they are known. There are neither lachrymal sinuses, inguinal pores, nor knee-brushes; the characters of the females, however, have not been observed, but it is most probable that they are provided with horns like the males, and have four teats. The horns themselves are round, annulated, and uniformly bent backwards, or in one species forwards; and there is, as in most of the species of the former division, a reversed mane on the shoulders and neck. These animals are confined to Africa, and, as far as we are at present aware, to the southern portion of it, yet seldom, if ever, passing the Orange River, and absolutely unknown in the neighbourhood of the Cape.

[The Blauwbok, *A. leucophaea*.]

53. The BLAUWBOK (*A. leucophaea*, Pallas) was formerly an occasional visitor in the district of Zwellendam, but has not been seen within the boundaries of the colony for the last thirty years. It is six feet in length, and three feet seven inches high at the shoulder; the head is nine inches long from the muzzle to the base of the horns; these are two feet two inches, measured along the curves; the length of the ears is eight inches, and that of the tail, with its terminating tuft, one foot. The horns are round, uniformly curved backwards, and marked with from twenty to thirty

prominent and complete rings, the last six inches being smooth, and the points very fine and sharp. The hide of this animal is perfectly black, and it is this colour reflected through the ashy-grey hair that communicates the dark blue shade which has given rise to the name of *Blauwbok*, or *Bluebuck*, by which it has long been known among the Dutch at the Cape of Good Hope.

The blauwbok lives in pairs or small families of five or six individuals on the open plains of South Africa, north of the Gareip or Orange River. It is dangerous when wounded, and during the rutting season in particular is said to attack indiscriminately every animal that comes in its way.

54. The TAKHAIITZE, (*A. barbata*, H. Smith,) beautifully figured by Mr. Daniell in the *African Scenery*, is a species which appears to differ from the blauwbok only by its long flowing mane, copious beard, and superior size. This animal inhabits the country in the vicinity of Latakoo, and is called *Takhaitze* by the Booshuanas. It is said to be as wild and ferocious that the natives are afraid to attack it openly with the *hassagai* or spear, as they do other game, but do take it generally in pitfalls covered over with sticks and earth. It is commonly found in pairs upon the open plains, but when disturbed makes for the wooded heights, which are thickly covered with the common mimosa, upon which both this animal and the giraffe delight to feed. The name *takhaitze* signifies a fierce or wicked beast, and expresses the dread with which the resolution and prowess of this powerful animal inspire the Booshuanas, who seldom venture to approach it openly.

55. The EQUINE ANTELOPE (*A. equina*, Geoffroy) is a large species which measures seven feet and a half in length, and four feet in height at the shoulder. The horns are much larger and heavier in proportion to their length than those of the blauwbok; they are, however, much of the same general form. This species, of which the native name has not been recorded, inhabits the same localities as the last two, living like them in pairs or small families on the elevated plains and low wooded hills of South Africa. It is abundant about the sources of the Gareip, and was found by Mr. Burchell in the vicinity of Latakoo.

56. (*A. Ellipsiprymnus*, Ogilby.) A description of this new species lately appeared in the *Proceedings of the Zoological Society*. The whole length of the animal from the muzzle to the root of the tail was seven feet three inches and a half; its height at the shoulder nearly four feet, and to the top of the horn upwards of seven feet; the horns measured thirty inches upon the curves, the ears were upwards of eight inches long, and the tail, with its terminal tuft, one foot nine. The horns are very thick and heavy; they spread widely outwards, are nearly straight for the first half of their length, and then turn forwards with a gradual and uniform curvature. They are surrounded with twenty-four prominent annuli, forming large knobs in front and deeply striated between, but nearly obliterated behind: the last six inches are smooth, and the points blunt. Next to the character of the horns, this species is most readily to be distinguished by a ribbon of pure white, which passes over the croup and down each hip, uniting between the thighs and forming a perfect ellipse, having the root of the tail in one of its foci, and contrasting most singularly with the dark rusty-iron grey of the surrounding parts. It is to this mark, which is so peculiarly characteristic of the species, that the name of *Ellipsiprymnus* refers; the native name of the animal is unknown.

The specimen from which this description was taken was brought to this country by Mr. Steedman, and exhibited with a fine collection of South African zoology at the Coliseum in the Regent's Park. It had been procured from a tribe of the Damaras, a nation who inhabit the country beyond the Great Namaqualand, and about twenty-five days' journey north of the Orange River. They described it as fierce and dangerous to approach.

XVII. The seventeenth section or subdivision of antelopes has all the characters of the group last described, except the horns, which are either of a spiral form themselves or else surrounded by a prominent spiral wreath throughout the greater part of their length. They are common to both sexes, very large and heavy in the males, but longer and more slender in the females. These animals are without either lachrymal sinuses, inguinal pores or brushes on the knees; they have naked muzzles, large hanging dewlaps, and the females are provided with four teats forming a small udder. The group contains two species, both native of South Africa

[The Canna, *A. oreas*.]

57. The CANNA, (*A. oreas*, Pallas,) improperly called eland or elk by the Dutch colonists of South Africa, and *impoof* by the Caffres, is considerably the largest of all the antelopes, being the size of a good horse, and measuring eight feet two inches in length and full five feet in height at the shoulder. The horns of the male are a foot and a half in length, very thick and heavy, almost straight till within three inches of the tips, where they bend outwards, attenuated at the points, and surrounded throughout the greater part of their length with a thick spiral wreath, which passes twice completely round them, and finishes by becoming indistinct near the points. Those of the females are longer and smaller, and the spiral wreath is, in some specimens at least, scarcely to be seen. The head is long and pointed, the ears are large, the neck thick, compressed on the sides, as in the ox, and furnished underneath with a loose hanging skin or dewlap, fringed along the margin with a border of long hair. There is likewise a large protuberance of the size of a man's fist on the larynx, and it was probably from this organ, which is likewise found in the elk of Europe, that the animal derived the name of eland, by which it is universally known at the Cape. From the centre of the forehead to the root of the tail, runs a short, erect mane of dark brown hair, which is reversed on the neck, but directed backwards, in the usual manner, along the spine of the back. The length of the spinous processes of the interscapular vertebræ produces a considerable and sufficiently remarkable elevation of the shoulders; but there is no actual hump, as in the camel or Indian ox, though at first sight such a formation might be supposed to exist. The tail is upwards of two feet long, and terminated by a tuft of long black hair. The colour of the body is uniform reddish-fawn on the upper parts, and white on the under; the head and neck ashy-grey, but in some individuals the latter colour extends over all the upper parts of the body.

The canna is a large heavy animal, which, when full grown, weighs from seven to nine hundred weight, and contrary to the usual rule observed among antelopes, is commonly extremely fat. Its flesh is, consequently, more prized than that of any other wild animal of South Africa, and the large muscles of the thighs, in particular, are held in the highest estimation when dried and cured, under which form they are denominated thigh-tongues. The character of this animal is very mild, and, as it were, predisposed to domestication; it is gregarious, and lives in large herds upon the open plains and low hills, the old males generally residing apart. Elands were formerly very common in the immediate neighbourhood of Cape Town, but were so much hunted, that they have long since ceased to frequent the inhabited districts, and are now rarely met with except in the most distant and retired parts of the colony. Being generally very fat and puffy, they do not run well, and are soon fatigued; it is even said that when hard run, a red oily perspiration has been known to ooze out from the pores of their skin, and that they occasionally drop down from plethora. Like most other animals when hunted, they always run against the wind. As the carcass is weighty and consequently difficult to transport, the great object of the hunters, in the chase of the canna,

is to turn their game in such a direction as to drive it close to their own residence before killing it; and, in fact, the Cape farmers, from long practice and intimate knowledge of the animal's habits, very frequently succeed in accomplishing this masterpiece of South African field-sports. They are so gentle that a man on horseback may penetrate into the very middle of a herd, without alarming them, and pick out the fattest and best-conditioned, and as the old bulls are commonly chosen on account of their greater size and weight, it not unfrequently happens that the herd is left altogether without a male.

58. (*A. canna*, H. Smith.) This is a species of which Colonel Smith has given a description, and which he supposes to be the *baastard* eland of the Cape colonists. Col. Smith is the only naturalist who has seen the skin of this animal: its horns and skull are found in several museums.

This species is said to be common in the Great Desert north of the Gareip, and to be occasionally seen on the Karroos of the southern bank. It lives in large herds.

XVIII. The eighteenth section contains a single species, distinguished by its short upright horns slightly bent backwards, common to both sexes, with a few transverse annuli at the base, and marked by deep longitudinal striæ almost to their extremities. The species is without either lachrymal sinuses, inguinal pores, or knee-brushes, but it has a complete naked muzzle, and the female is furnished with four teats. As the former division seemed to unite the antelopes with the oxen, so this seems to be intermediate between them and the goats, being about the same size as these latter animals and inhabiting similar localities. The only known species is

59. The GORAL, (*A. goral*, Hardwicke,) first described by General Hardwicke in the *Linnean Transactions*.

The goral inhabits the kingdom of Nepal, and lives in large herds upon the elevated plains which crown the lower ridges of the great chain of the Himalayan mountains. It is wild and fleet, and when pursued flies to the rocky hills, where it easily escapes the hunter, and is indeed rarely taken except by stratagem. Its flesh is considered excellent venison. It is entirely confined to the cold upper regions of Nepal, and is incapable of bearing the sultry heat of the plains of Hindustan.

XIX. The nineteenth group contains a single species like the goral, a native of Nepal and upper India, but differing from all those which we have lately been discussing by the development of large suborbital sinuses, which shows a return to the characters of the common antelopes. The horns are common to both sexes; short, parallel, slightly curved backwards as in the goral, and traversed throughout the greater part of their length with longitudinal striæ, crossed by transverse depressions, and thus marking the whole surface of the horns with alternate rows of small pits and little pearly excrescences; the points only being smooth and sharp. Besides these characters, the present section is distinguished by a complete naked muzzle, four teats in the females, and neither inguinal pores nor knee-brushes.

60. The THAR (*A. thar*, Hodgson) was described for the first time in a paper by B. H. Hodgson, Esq., British resident in Nepal, read before the Zoological Society, and printed in the second part of the *Proceedings* of that body.

The thar inhabits the central region of Nepal, at an equal distance from the snows of the Himalayan range on the one hand, and the sultry heats of the low plains of India on the other. It is the most common of all the wild ruminants which are found in that country, and its chase is the favourite exercise and amusement of the hill tribes; its flesh is, indeed, coarse, but there is plenty of it,—and these rude people are easily satisfied on the score of quality, provided the quantity be sufficient. Its habits are wild and solitary; it is seldom found in herds, however small, and the grown males especially live apart in the mountains, and never seek the society of their species except during the rutting season. As might be supposed from its heavy make and short stout limbs, it is a slow runner, and soon brought to bay, but it leaps well, and makes its way over broken ground with greater ease than in open level situations. It is found from the eastern confines of Nepal to the banks of the Sutledge, but abounds especially towards the east.

XX. We are now arrived at a group of antelopes of which two species at least are well known, and one has been celebrated under the name of *bubalus* from the most remote periods of Grecian and Roman literature. This group is distinguished by having heavy, thick, annulated horns, at

first inclining slightly forwards, and then suddenly bent backwards, so as to form a prominent angle or shoulder in front. The muzzles are small and not so completely developed as in some of the other groups; the lachrymal sinuses are also small, and instead of opening by a fold in the skin, consist simply of a small gland on its surface, almost concealed by the surrounding hair, and only to be distinguished by the viscous matter which exudes from them. The character of the inguinal pores has not been observed, but the species are without scopæ, and the females are provided with horns and have only two teats. The species is spread over the whole continent of Africa, and lives in large herds on the open plains and karroos.

[The Beker-el-Wash, *A. bubalus*.]

61. The BEKER-EL-WASH (*A. bubalus*, Pallas) is about the size of the largest stags, and is particularly remarkable for the great length of its head, and its narrow, flat, and straight forehead and face.

This animal, called *Beker-el-Wash*, or wild ox, by the Arabs, is common in every part of northern Africa, living in numerous herds on the confines of the Tell or cultivated parts, and the Sahara or Desert, and also, according to Captain Lyon, upon the mountains south of Tripoli. Barbary seems to be the chief habitat of the species, but it sometimes happens that a few individuals find their way across the Desert to the banks of the Nile, where, however, they are seldom seen, and, as it is said, only when they stray from their native habitat. At the same time it is to be observed, that its representation occurs among the hieroglyphics of the temples of Upper Egypt. Dr. Shaw informs us, that the bubalus is naturally of a familiar disposition, and that the young calves frequently mix with domestic cattle, and soon learn to attach themselves to the herd without attempting to escape afterwards. They fight like the common bull, by lowering the head, and striking suddenly upwards with the horns, which are formidable weapons either for attack or defence.

62. The CAAMA (*A. caama*, Cuvier) is a species of South Africa, nearly allied to the beker-el-wash, and long confounded with it.

The caama, called *Hartebeest* by the Dutch farmers, inhabits the plains of South Africa, and is the most common of all the large antelopes in that country. It resides in large herds, and is a favourite object of pursuit with the natives and colonists. Its pace, when at full speed, resembles a heavy gallop, but is tolerably quick notwithstanding; and the animal has a habit of frequently stooping to gaze at its pursuers when it has got to any distance a-head of them. Its manners are sufficiently mild and tractable, but when put upon its defence it makes good use of its powerful horns, dropping on its knees before charging, and after advancing some distance in this position, darting suddenly forwards with great force against its adversary. The flesh is rather dry, but of a fine grain, more nearly resembling the beef of the ox than that of any other antelope, except perhaps the canna, and it has a high game flavour which makes it universally esteemed. The female produces but a single calf,

which she brings forth in September or April, and which, if taken young, is easily domesticated.

63. The SASSABY (*A. lunata*, Burchell) is a species at present very imperfectly known. It is found in the Booshwana country, where, however, it would appear that the species is rare, as Mr. Burchell, the only traveller except Daniell that mentions it, met with but a single specimen. In many respects the descriptions of Burchell, and of Colonel Hamilton Smith, who also has given one, are both imperfect, but the drawing of Daniell, in his *Sketches of African Scenery and Animals*, supplies most of their omissions, and clearly shows at least that the animal belongs to the present division, if it does not supply the more minute details. The meat of the specimen shot by Mr. Burchell was tender and well tasted, and the name of *Kaama*, which his attendants bestowed upon the animal, shows that they consider it as a kindred species with the Hartebeest of the colonists, the *Antelope caama* of the last article. The Booshwanas call it Sassaby.

XXI. We are now arrived at the last and perhaps the most extraordinary of the small groups into which we have found it convenient to subdivide the extensive genus of antelope. The distinguishing characters of this group are found in the horns, which are common to both sexes, and which, after first expanding over the whole upper part of the skull and forehead, like a broad helmet of bone, curve downwards between the eyes, and then suddenly turn upwards, becoming round and attenuated as they advance, and ending in moderately sharp points. They have no annuli, but are rough and scabrous at the roots, and smooth toward the points. The head is heavy like that of the ox, and terminated by a very broad muzzle, which expands on each side into a thick muscular flap, which fits into each nostril, and covers it like a lid or valve. The lachrymal sinus, as in the last section, consists of an external gland, which is placed below the anterior angle of the orbit, and concealed in a tuft of long feathering hair which entirely surrounds it. There are neither inguinal pores nor brushes on the knees; the females are provided with two mammae. There are three distinct species belonging to this group, one of which is generally supposed to be the *Katoblepas* (*κατοβλεψ*) of the ancients. (Plin. *Hist. Nat.* viii. 21. The singularity of their forms renders them very remarkable; the head and horns are those of an ox or buffalo, the tail, neck, and mane resemble those of the horse, and the body and limbs have the light taper form and round contour that distinguish those of the stag. The whole three species inhabit the open plains of South Africa to an unknown distance in the interior. They live together and form extensive herds.

The Gnu, *A. gnu*.

64. The GNV (*A. gnu*, Gmelin) is about the size of a well-grown ass. The neck, body, and tail precisely resemble those of a small horse, and the pace also, which is a species of light gallop, is so perfectly similar, that a herd of gnus, when seen at a distance flying over the plains of South Africa, might be readily mistaken for a troop of the wild

zebras or quaggas which inhabit the same localities, if their dark and uniform colour did not distinguish them.

The gnus live in extensive herds on the karroos of South Africa; they are naturally wild and difficult of approach, and when wounded will turn upon the hunter and pursue him in turn, dropping on their knees before making an attack, and then darting forwards with amazing force and velocity. When first alarmed they commence by flinging up their heels and capering like a restive horse, tossing their heads and tails, and butting at the mole-hills or other objects, but immediately after taking to flight, and traversing the desert with a speed which soon carries them beyond the reach of danger. They do not run in a confused crowd like sheep or oxen, but in single file following a leader, and have a pleasing appearance as they skim over the level plains. They are said to be subject to a cutaneous eruption at particular seasons of the year, which they sometimes communicate to domestic cattle, and which invariably ends in death.

65. The KOKOON (*A. taurina*, Burchell) is of a larger size than the gnu, to which, however, it is very similar in its external form and proportions.

The habits and manners of the kokoon closely resemble those of the gnu, but it possesses neither the speed, spirit, nor activity of that animal. It is sometimes found solitary, but more frequently in large herds, and inhabits the open plains and karroos in the country of the Tambookies and Booshwanas; it never associates with the gnu, which frequents the same localities, at least about Latakoo, but which it appears to replace along the eastern coast of South Africa, as the following species seems to do along the western. The species has been observed in the situations here mentioned by Professor Lichtenstein, Messrs. Truter and Somerville, Burchell and Thompson. Kokoon is its Booshwana name.

66. The BRINDLED GNU, (*A. gorgon*, Hamilton Smith,) a very distinct species from the two last described, is however known only from a specimen in the Museum of the London Missionary Society, which was brought from South Africa, and most probably from the country of the Namaquas or Damaras who inhabit the western coasts about the mouth of the Gareip, or Orange River.

Colonel Smith supposes, with great probability, that this species is the *Baas*, not, however, of the Namaquas as he states, but of the Dutch Boors of South Africa, who are in the habit of making occasional excursions into the Namaqua country, and in whose language the word signifies *master*, and most probably refers to the bold and resolute character of the animal. It appears to be the variety of gnu mentioned by Le Vaillant in his *Second Voyage*.

In the preceding enumeration of the species belonging to the extensive genus *Antilope*, as it is at present constituted, we have carefully avoided the multiplication of fictitious species, by rejecting all those of which the authenticity is in any degree doubtful. Our list of species will, therefore, be found to differ in many instances from those contained in general catalogues, but it is hoped that it will, at the same time, be found to contain all that is really certain in the present state of the science. Those who desire to pursue the subject further, must consult the professed treatises on mammalogy, and the various detached notices scattered through the works of the different Asiatic and African travellers.*

ANTENNÆ, horn-like members placed on the head, and peculiar to insects and crustaceous animals; their functions are not well understood, and have given rise to several very different opinions among naturalists. The term is derived from the Latin *ante*, 'before,' and was applied by the Romans to the sail yard of a ship. In insects, they are uniformly two in number; but in crabs and lobsters there are more than two. They are connected with the head always near the eyes by means of a ball (*bulbus*) and socket (*torulus*). They are composed of minute cylinders or rings successively added to each other, to the number of thirty in some butterflies, and thus forming a tube which incloses

nerves for sensation, muscles for moving, as well as air-pipes and cells, all of which are figured with minute precision by M. Straus-Dürckheim, in his splendid work *On the Anatomy of the Cockchafer*, published at the expense of the Institute of Paris.

The form of the antennæ is exceedingly various, some being simple and some feathered, clubbed, comb-shaped, in endless diversity. In moths, the female is distinguished from the male by the antennæ being more simple. In some moths and beetles the antennæ are very long compared with the length of the body, whereas in the house-fly, and some other two-winged flies, they are very short. Their length does not depend on the number of joints, for they may be long when composed of only three or four pieces, and short when composed of ten or more pieces.

With respect to the functions of the antennæ, it is the most common opinion that they are organs of touch, and are, on that account, often termed feelers; 'but,' as M. Straus-Dürckheim justly remarks, 'this conjecture is founded upon facts imperfectly investigated, if not altogether false. I have made numerous researches on this subject, and I have never been able to satisfy myself that insects examine objects by feeling them with their antennæ. On the contrary, I have rarely observed these animals touch anything with these organs, and when this did happen, it appeared to be only by accident, and not at all from design. Many insects, besides, have their antennæ so short, that they would be obliged to stand erect upon their heads in order to come at the bodies which they might thus wish to explore, and for this their feet are certainly much better adapted.'

'Since,' continues M. Straus-Dürckheim, 'almost all articulated animals possessing a solid skin (*peau*) have antennæ, which are furnished with nerves of an extraordinary thickness in proportion to their own size, there cannot remain a doubt that they are organs of some sense, and that too a very acute one.'

'I have said that insects are proved, by observation, to be furnished with an organ of hearing. It is, indeed, scarcely probable that creatures, such as the tree-hopper (*cicada*) and the locust (*locusta*), to which nature has given the faculty of producing a peculiar sound by means of an appropriate organ, should, at the same time, be deprived of the means of hearing such sounds, inasmuch as these can have reference only to their own kindred. It is still further proved that these insects share the faculty of hearing along with all other living beings, by their ceasing to sing the instant they fear they have been discovered.'

'When observing the various actions of insects we see them suddenly stretch their antennæ forwards in case of noise, danger, or, in general, when anything is done to attract their attention; and they keep them thus stretched forward as long as their attention continues, a circumstance which proves that the antennæ serve the purpose of apprising them of what passes at a distance, and consequently must either be organs of hearing or organs of smell. M. Réaumur, (*Mém. des Insectes*, i. 643,) while he rejects the opinion that the antennæ serve to explore objects, thinks it possible they may be the organs of some unknown sense, or of smell. The latter opinion, however, is supported by no fact either anatomical or physiological; nor is it at all even probable, inasmuch as the antennæ are not soft and lubricated, as observation proves to be necessary for this kind of sensation; it appears to me more plausible to infer that the antennæ serve for the perception of sounds. This opinion is founded partly on the analogy of what occurs in the larger animals, who prick up their ears under similar circumstances in order to hear better; and partly on comparison of the organs of hearing in the first of the vertebrate animals (*vertebrata*), and the antennæ of articulated animals, where we observe a sort of transition occurring in the lobster and craw-fish (*astacus*), a genus in which this organ occurs in the simplest form, compared with that of superior animals.'

'The solidity of the envelope of antennæ renders these organs well adapted to undergo the same vibrations as the air, in the same manner as the strings of an Æolian harp vibrate and emit various sounds according as they are differently struck by the air. In this view, however, we might infer that nature would have made antennæ in the form of rods, consisting of a single piece, in order that they might be more susceptible of vibrations; but it ought to be considered, that these organs would, by such a conformation, have been much exposed to breaking, while, in consequence of their jointed form, they have the advantage of regulating

* The length to which this article has extended requires some explanation. The genus *Antilope*, embracing a great variety of species, has presented difficulties to naturalists in its many sub-divisions into groups; and one species has frequently been confounded with another. A complete and connected view appeared, therefore, desirable to be here attempted. According to our usual plan, we should have described the species under their respective heads; but this would have prevented that comprehensive arrangement which the writer has here aimed at. We insert this note to prevent an impression that the same principle will be carried into other zoological articles.

the degree of vibration at pleasure, as may indeed be observed when insects listen with attention; I mean, that the joints of the antennæ perform the same functions as the chain of small bones in the chamber of the human ear, inasmuch as they form a similar chain, and transmit the vibrations of the air to the auditory pulp.

Professor Bonsdorff of Abo in Finland came to embrace a similar opinion from his own observations, in opposition to those of Linneus and Bergmann with whom he was contemporary. His paper on the subject is long and desultory, but the following passage is worth quoting. 'No evidence more clear,' he says, 'could be desired of the sensibility of the antennæ to quick sounds, than what occurred to me last summer in my garden. I observed in a morning walk, undertaken for the purpose of catching insects on the hazels, that while standing in the shade a nut weevil was sitting quietly at a distance upon a leaf, with the antennæ hanging down as if they were asleep, on which account I directed a pocket telescope to the spot, which was above five feet distant, and therefore convenient for viewing the insect. The point of view being thus determined, I made a loud sound, and I was delighted with the opportunity of seeing the weevil not only roused, but the antennæ which had been hanging down became elongated, and, being full of joints, struck by the undulations of sound they extended themselves and remained on the alert till alarmed again by a fresh sound. All my observations agreed in this one circumstance of the antennæ being erect as soon as they were put on the alert; they were moved hither and thither by means of loud sounds, but they disregarded such as were very small. These they may be said to have drunk in; and if alarmed by new sounds they rejoiced when they could effect their escape as soon as possible, and preserve life and safety by the most rapid flight. So I have observed very frequently when the antennæ were folded up in the *Leptura*, *Elateres*, *Curculiones*, *Papiliones*, and *Apes*; nay, even the house-flies, as soon as they were moved and excited by irregular sounds or noise, would erect their antennæ and betake themselves to flight without any other excitement.'

We have deemed it best to give the very words of these able naturalists upon a point which is doubtful, or at least obscure. Some additional experiments and arguments illustrative of the same view are given in the volume on *Insect Miscellanies*, chap. iv. in the *Library of Entertaining Knowledge*.

There is one other subject connected with the antennæ which requires notice:—the younger Huber has attributed to ants the use of certain signs made with these organs, which he terms antennal language, understood not only among ants themselves, but also among the aphides, on which they depend for the excretion popularly termed honey-dew. The motions of the antennæ, however, to which he refers in proof of his views, do not, so far as we can judge, authorize us to conclude that they are used in the way of language, any more than to theorize in the same way upon the bills of nestling birds which are opened to receive food, or their wings which are opened and vibrated rapidly while they receive it. That there is nothing peculiar in this alleged antennal language, so far as the aphides are concerned, any one who chooses may prove by taking a pin or a camel-hair pencil and gently touching the aphids, when it will eject the honey-dew as readily as in consequence of being touched with the antennæ of an ant. This we deem to be quite fatal to M. Huber's conclusions.

ANTEPAGMENTA. This is an antient term for the jambs of a door, or, as they are familiarly termed, the door-posts.

ANTEQUERA, ANTIKARIA, a town of Andalusia, in the province of Malaga. The old town is built on a hill, but the new one stands in a plain surrounded by mountains. Its vega (plain) is one of the richest in the province, owing to its being irrigated by the two rivers Guadalhorce or Guadaljorce, and Lavilla, and produces all sorts of grain, fruit, wine, and oil. The neighbouring mountains abound in fine wood, white, black, and red marble, limestone, and gypsum. About eight miles north-west of the town is a lake of salt-water, four miles in length and a mile in breadth, which, in the summer months, from the watery particles being evaporated, becomes a solid mass of salt.

Seven miles south of Antequera is the Sierra del Torcal, a mountain elevated 4219 feet above the sea, and consisting principally of marble and limestone. The sandstone which united the rocks being now decomposed, the assemblage of

rocks remaining presents the most singular appearance. At a certain distance they assume the forms of houses, temples, and even figures of men and animals. The order of their arrangement is such that they form streets, lanes, and squares, and indeed, such is the illusion produced to the eye, that one might almost be tempted to believe the old Moorish story, that it was once a populous town, miraculously converted into stone. Travellers ought to be aware how they venture into this intricate labyrinth without a proper guide, as they run the risk of never finding their way out of it again. The spaces left between the rocks form as many natural meadows, in which are fed numerous herds of bullocks, sheep, and goats.

The Roman municipium Singilis was situated about four miles north of Antequera, and another Roman town, Nescania, stood eight miles westward, on the spot where now is a village called Fuente de la Piedra, (the stone fountain,) on account of a fountain springing there, the water of which is said to possess the property of curing the gravel. Several Roman inscriptions bearing the names of both these towns, as well as of Antikaria, have been preserved in the stones of the *Arco de los Gigantes*, or arch of the giants, built in 1585, at the entrance of the old city.

Antequera was conquered from the Moors in September, 1410, by the Infante Don Fernando, who was afterwards king of Aragon. King Juan II. gave it back afterwards to the kings of Granada; but the inhabitants refusing to submit, headed by their gallant alcaide, Rodrigo de Narvaez, boldly defended their independence, and compelled the Moors, who besieged them twice, to abandon the place. This is the origin of the motto '*Antequera por su amor*,' 'Antequera for its sake,' which is on the arms of this city.

The manufactures of the inhabitants consist of common woollen stuffs, silk, leather, paper, and soap. The population amounts to 22,732 souls. There are at Antequera, a collegiate church with twelve canons, four parish churches, eleven convents of monks, eight of nuns, an ecclesiastical seminary, an hospital, and an alms-house.

Antequera is in 37° 9' N. lat., 4° 32' W. long.

See Miñano; Ponz, *carta* iv., n. 50 to the end, tom. xvii.

ANTHELMINTICS, from two Greek words, signifying means used to expel worms from the intestinal canal, and to prevent their formation. Though the origin of worms in the intestines has been a subject of enquiry and controversy for many ages, we are far from having arrived at a satisfactory conclusion respecting it. While some have regarded them as the result of what is termed *spontaneous* or *equivocal generation* occurring in the intestines, (see Aristot. *Hist. Anim.* v. 19.) others have maintained that they are introduced into the stomach from without, either along with our food, or in some other way, in so small a form as to be unobserved. Great difficulties attend either view of the question. If it is held that they come from without, the sources of them have never been seen, and cannot be pointed out. The opinion of their spontaneous generation is also rendered very improbable, both by the consideration that such an occurrence would be at variance with the present universal mode of production of all other animals, which invariably issue from parents similar to themselves, and by the fact that, however the worms may be at first produced, when once developed in the intestines, they are propagated like other animals of the same grade in the scale of organization, viz. by parents of distinct sexes; and the *ova* or *eggs* which the female produces are both to be seen in the oviducts, (see fig. 1. a.) before they escape, and also are to be found among the contents of the intestines previous to their development as perfect worms. The settlement of this question would be interesting, and might prove useful in directing us in our prophylactic treatment. But as we cannot pretend to this in the present state of our knowledge, we must refrain from further discussion of the subject, and rather enquire into the circumstances and conditions favourable to their development and the means of counteracting them.

The causes of worms, and of the tendency to their formation, may be divided into, 1. general and local, referring to the residence, and, 2. special, referring to the individual manifested by them, his constitution, habits, diet, &c.

Of the first division, the most general is climate. In certain countries worms prevail more than in others; and hence their frequency in Holland, where there is no want of personal cleanliness, or attention to the food; but the constant moisture of the atmosphere, both producing general weak-

ness, and acting hurtfully on the skin,—the state of which, owing to the sympathy existing between it and the digestive organs, influences greatly the health of the body,—farther predisposes to their development. We see the same causes operate in producing the rot in sheep, which is always accompanied by the presence of a worm (the *Distoma hepaticum* or *fluke*) in the liver; and we shall find the same means prove successful in preventing their formation in both cases: as only sheep feeding in wet pastures, such as marshes, are subject to the rot.

Dwelling in an impure air, where there is not sufficient ventilation, prepares the body for becoming the seat of worms, and hence their greater frequency among the crowded inhabitants of towns than among the peasantry.

The effect of these general causes is to produce a weak state of the system, the existence of which, however occasionally, seems the first requisite for the development of worms. When in addition to these there are other causes which operate only on individuals, we perceive the reason why one person becomes subject to worms, from which another person continues exempt. This naturally conducts to the second set of causes, connected with the individual affected by these parasites. These we shall find to be a constitution, either hereditarily weak, or debilitated by sedentary occupations and improper diet. Accordingly, those most subject to worms are females and children, especially of a scrophulous habit. In these last there exists very commonly weakness of the digestive organs, along with an immoderate craving for food, which injudicious parents and nurses are too apt to indulge—regarding it as the sign of a good appetite—by which more aliment is introduced into the stomach than it can conveniently digest, and consequently the stomach and bowels become clogged, both by the undigested matters remaining in them, and also by the unhealthy secretions, which, under such circumstances, are invariably poured into them. The articles given to satisfy this craving, which generally shows itself between meals, are almost always those which experience has shown to be the most calculated to favour the production of worms, viz., articles of too farinaceous a kind, as biscuits, cakes of different sorts, or bread and butter, or cheese: for milk, and the preparations of it, which we have just mentioned, seem to dispose to the formation of worms more decidedly than anything else.

The presence of worms in the intestines cannot always be determined by any one, or even by the concurrence of many symptoms, for enormous tæniæ (*tape-worms*) have sometimes been passed, of the existence of which not the least suspicion was entertained by the individual; nor was any derangement of the health observable. But we are justified in suspecting them to be present where the appearance and expression of the countenances are much altered from the natural state; when it is of a pale, somewhat leaden, hue, subject to sudden flushings, often limited to one side of the face, where the eyes have lost their brightness, the pupil is enlarged, and the lower eye-lid surrounded by a livid circle. In addition to these symptoms, the nose is often swollen, and affected by an intolerable itching, or frequently bleeding; there are pains in the head, with ringing of the ears; the tongue is coated, and the breath disagreeable. The appetite is very variable, sometimes there is none, at other times it is ravenous. There is often a feeling of sickness and a disposition to vomit; occasionally there are violent colics, the bowels irregular, seldom costive, more frequently loose; the stools slimy, sometimes tinged with blood; the belly swollen and hard, while there is generally a wasting of the rest of the body; the urine is rarely clear, often of a milky appearance. The sleep is disturbed, and the child grinds the teeth; during the day, it is indolent, and very variable in temper.

It is necessary to be thus minute in stating the symptoms of worms, as, sometimes on very slight grounds, individuals have been subjected to a long and severe course of treatment for worms, when none existed; while, too often, they are allowed to commit their ravages unmolested, and to plunge the unhappy victim into a state of great misery and suffering, and even to lead to a fatal termination. We are not willing to attach full credit to all the horrible consequences attributed to worms, but that they often produce many serious diseases, and aggravate others, is certain.

The number of different kinds of worms infesting the stomach or intestines of man is not very great, but they propagate their species often with astonishing rapidity. We

shall enumerate the most common sorts, following the nomenclature of Bremser, (*Lebende Würmer in lebenden Menschen*. Wien, 1819; also translated into French, by Dr. Grundler, Paris, 1828. *Traité des Vers Intestinaux*).

The *Trichocephalus dispar*, (or *long thread-worm*), found in the upper part of the large intestines (or *Cæcum*), *Oxyuris vermicularis*, (*Ascaris vermicularis*, the *maw*, or *thread worm*), which inhabits the rectum, or lowest intestine; *Ascaris lumbricoides*, (the large round worm; mostly found in the small intestines; *Bothriocephalus latus*, (*Tænia lata*, the *broad tape-worm*), found in the small intestines, (principally of the inhabitants of Russia, Poland, and Switzerland, seldom met with in Britain;) *Tænia solium*, (the *sa-worm*), in the small intestines, generally alone, but occasionally three or four together: the *Distoma hepaticum*, (or *fluke*), is sometimes found in the liver and gall-bladder of man, but more commonly of sheep, goats, &c.

The worms which are occasionally found in other parts of the body are not under the influence of the medicines termed *anthelmintics*, and we therefore leave them unnoticed here.

To assist us in distinguishing the particular kind of worm present in the intestinal canal, and to regulate thereby our treatment, it is proper to mention that the maw, or thread worm, and large round worm, are most common in youth, and the tape-worm in adult age.

From what has been said above, the principles of treatment may readily be deduced: these are, to strengthen the individual, and weaken the worms, which facilitates their expulsion, and diminishes the tendency to their formation. This last is a point of great practical importance; for not only is it of little use to expel worms already existing in the intestines, unless we remove the tendency or disposition to their production, but, very frequently, many of the articles inconsiderately administered, (which however are regarded as valuable anthelmintics, because, by their operation, they bring away worms,) often do more harm to the individual who takes them than to the worms. It is clear that all articles which by their sharp angles merely irritate the worms must do much more injury to the inner coat of the stomach and intestines, and cannot possibly be introduced or insinuated between the mouths of the animals and the surface to which they are attached. The wood-cut (fig. 4) shews by what a number of hooks the *tape-worm* attaches itself to the gut. When we see these, need we wonder at the difficulty of expelling this formidable and most determined parasite?

The means employed to effect the ends proposed are very numerous, but reducible to three heads: viz., those which by increasing the peristaltic motion of the intestines, displace the worms, and often occasion their expulsion, as purgative medicines of different kinds; those which tend to increase the strength of the stomach and intestines, and system generally, as tonics, or analeptics; and lastly, those which are conceived to act in an especial manner on the worms, dislodging, weakening, or killing them—or anthelmintics, in the strict sense of the word. Our means must be varied, for not only are the different kinds of worms limited to different parts of the intestinal canal, and the species of worms infesting it different at different periods of life, but particular substances are found to be more efficacious against one species than against others.

As a part of the general treatment of worms, purgatives are indispensable, and those should be selected which bring away the greatest quantity of slime; but the frequent repetition of such is inexpedient. Calomel with jalap, or scammony may be given, with the interval of two days between each dose, two or three times, followed by tartrate of antimony in very small doses, for a week: this may be succeeded by aloes, with antimonial powder, which last being laid aside, preparations of iron alone, or with gentian and canella, may be united with the aloes. This plan may be pursued, whatever be the kind of worm supposed to be present, being merely intended to improve the general health of the patient. When the strength is somewhat increased, cold, which is very pernicious to the worms, may be added to our means of cure, and employed in various ways. Large quantities of cold water, rendered still colder by dissolving in it, immediately before drinking, a quantity of common table-salt, or muriate of soda, may be taken. Sea-water may also be drunk with great benefit.

Among our purgative means we must not omit to mention sulphate of potass and rhubarb, to which, if there be ner-

vous symptoms present, such as a tendency to epilepsy or hysteria, valerian may be advantageously added. Different mineral waters are of great service, particularly in the treatment of the maw-worm. These both remove the slime in which the worms nestle, and diminish the tendency to its formation. With this view we may have recourse to the Beulah Spa at Norwood, to Cheltenham, and above all, to the sulphureous springs of Harrogate, followed by chalybeates there, or at Tunbridge.

The means of strengthening the digestive organs, consist of tonic and astringent medicines, both vegetable and mineral. Vegetable bitters are doubly advantageous, since they both strengthen the stomach, and prove direct poisons to the worms: of these, the best are chamomile tea and infusion of quassia, or gentian, to which muriatic acid, or tincture of muriate of iron may be added; for children the tartrate of iron, being almost tasteless, is advisable. The utility of vegetable bitters is proved by the fact, that wherever the *menyanthes trifoliata*, (bog-bean,) or the tormentil, grows, however damp the pastures may be, the rot never infests the sheep. A similar immunity from the rot is generally enjoyed by sheep fed on the salt marshes, or where salt is regularly mixed with their food. (See Reports of Lord Somerville.) The omission of a proper quantity of salt with our food favours the engendering of worms. The great tendency to the formation of worms in Holland has been mentioned, and when 'the ancient laws of that country ordained men to be kept on bread alone, *unmixed with salt*, as the *severest* punishment that could be inflicted upon them in their moist climate, the effect was horrible; the wretched criminals are said to have been *devoured by worms*.' The medicines enumerated constitute the most effectual means of preventing the return of worms; those which follow are deemed the best for expelling particular kinds of worms. The tape-worm (*Tænia solium*) is almost invariably expelled dead, by a large dose of oil of turpentine; and even the *long round worm* is influenced by it in somewhat smaller doses. Scarcely any other article need be employed, unless the disagreeable smell and taste be objected to, when the *brayera anthelmintica* should be given as at once safe and efficacious: we might naturally expect this result, since it belongs to the same natural family tribe as the tormentil, viz. the *Rosaceæ*. The root of the pomegranate is much esteemed in India. No reliance should be placed on the root of the male fern, as it is only useful against the *Bothriocephalus latus*, or *broad tape-worm*, which, though common in Switzerland, is rare in Britain.

The *long round worm* is almost invariably expelled by the *Spigelia Marylandica*, or Indian pink, which belongs to the same natural family as the bog-bean, or water trefoil, viz., the *Gentianæ*. The *Oxyures*, or maw-worms, are the most troublesome to the patient, and the most difficult to

remove, as medicines taken by the mouth are too much altered before reaching the rectum to produce any great effect. After the employment of the above-mentioned general measures, we should use local means only. The intolerable itching which they occasion about the rectum, is best relieved by a lavement of sweet-oil. A lavement of very cold water, or lime water, may be useful, if after it, a portion of aloes be introduced, and left to dissolve in the bowel. Injections of tobacco, and the use of all such dangerous articles as bear's-foot, (*Helleborus foetidus*), are to be avoided. The same may be said of tin-flings, cowhage, and all things which can act only as mechanical irritants.

ANTHEM, in music, a word of doubtful origin, but supposed to be derived from *ἀντιφωνία* (see ANTIPHONY), because antiently sung alternately by the two sides of the choir: it then, however, was originally but a simple hymn, or kind of psalm tune. The term is now applied to those compositions in use in all our choirs, set to verses from the psalms, or to any portion of the Scriptures or liturgy, and the *anthem* may be for one, two, or any number of voices, but rarely exceeds five parts.

There are three kinds of *anthem*,—*verse*; *full*, with *verse*; and *full*. The first, which is solo, or duet, &c., has only one voice to a part, and, requiring nicety of execution, is generally assigned to the best singers in the choir. The second, consisting chiefly of chorus, is sung by the whole choir, but the verse parts by single voices. The third is chorus wholly, and performed by all the voices.

The English school has always excelled in the composition of *anthems*. Tallis led the way in full anthems, and was immediately followed by Birde and Farrant. Their harmony is quaint, but indescribably solemn, and in true keeping with the Gothic structures wherein it was first heard, and still continues to resound,—fanes whose 'high embowed roofs' soften and blend the tones of the 'full-voiced choir below,' and give an effect to the music which Milton might well say, 'brings all heaven before our eyes.' Orlando Gibbons soon succeeded those masters, and in the same kind of anthem—but highly elaborated, and enriched with whatever florid counterpoint could supply—brought forth works that have always been, and must ever continue to be, admired, not for their ingenuity only, but their effect. Blow was one of the first to introduce the *verse anthem*, but his compositions, dry and stiff, are become nearly obsolete. Purcell, his pupil, produced numerous anthems, some few of them exhibiting striking beauties, and much grandeur of conception, but the majority, being written in the manner of his master, are more learned than pleasing. Michael Wise and Jeremiah Clark made our cathedrals acquainted with natural and pathetic melody; and Doctors Croft, Greene, Boyce, and Nares, in anthems of all the three species, united air and harmony, genius and learning, in a manner unequalled; though it is to be regretted that their works are so little known, except where choir service is performed, and so seldom heard, if ever, in our parochial churches and other places of worship.

ANTHEMIS is the genus of plants to which the useful herb chamomile belongs. It is of the compound flowered order, and is distinguished by having the scales that surround its flower-heads membranous at the border, like those of a chrysanthemum, from which genus it, in fact, differs chiefly in the receptacle of the flowers being furnished with little chaffy projections.

Anthemis nobilis, or chamomile, is frequent in a wild state on many of the commons near London, where it adds a peculiar richness of colour and fragrance to the turf. It is a very dwarf plant, with finely-cut leaves; its flower-heads are white in the ray, but deep yellow in the disk: all the parts are intensely bitter, but especially the little yellow flowers of the disk: for this reason the wild blossoms are far more efficacious than those of the cultivated sort, in which there is scarcely any disk; the flowers of the ray having almost entirely usurped their place. Besides the bitter principle for which chamomile is so celebrated, it has been found by chemists to contain camphor and tannin, and also a volatile oil of a beautiful blue colour.

There is another wild plant, called *Anthemis cotula*, or mayweed, which must not be confounded with chamomile, in which it bears great resemblance: it may be distinguished by its being an erect branching plant, with an exceedingly disagreeable and powerful odour.

Anthemis tinctoria is used in France by the dyers for the sake of a brilliant yellow tint, which is obtained from it.

1. Two joints of the *Tænia solium*, tape-worm, magnified, in one of which are seen the numerous ova, or eggs. a. The oviduct by which they pass out. 2. Some of the eggs, much magnified. 3. Head of the animal, seen in front to show the mouth in the centre, surrounded by a circle of hooks, and the four suckers, a. a. a., of which two are alternately protruded, and two retracted. 4. The mouth with its hooks. 5. Two of the hooks, very greatly magnified. 6. A sucker, much magnified.

ANTHER. The part thus named in plants is the upper half of the stamen, or fertilizing organ, of a flower; it is the case which contains the pollen in which the principle of fertilization is inclosed. An anther generally consists of two hollow lobes, lying side by side, and united by a fleshy body, which is sometimes of great size, but more usually extremely small, and called the connectivum. Their position is, for the most part, such that, when they open, the line by which they burst is next the stigma, so that the pollen they emit may fall upon that organ; but to this there are many exceptions, and we sometimes find the anther so placed, that it is impossible to explain the manner in which its pollen can reach the stigma, without supposing the pollen to be conveyed by insects.

The deviations from the usual structure of the anther are caused, in most cases, either by the augmentation or suppression of some of its parts. For example, the lobes sometimes grow together into one, and then the anther is only one-celled, instead of two-celled; or one of the lobes of the anther never grows, and then also it is one-celled. In other cases, each lobe is divided into two partitions by a plate that springs out of its back in the inside, and then an anther becomes four-celled. Anthers generally open by a line that passes along the face of the lobes from end to end; but it not unfrequently occurs, that a portion only of this line opens, and then they are said to burst by pores, as in the potato blossom.

The most singular deviations from regular structure are those in which the connectivum becomes excessively enlarged. In the hand-flower of Mexico, it is coloured deep red, and so long and fleshy as to be far larger than the lobes, and to resemble the talon of a bird of prey. In many of the ringent flowers it spreads horizontally, till the lobes are quite separated from each other at the base, and thrown from a perpendicular into a horizontal position; and in the common sage it forms a long, flat body, which looks exactly like a second filament placed across the first one.

The dehiscence, or act of bursting, of the anther, should take place at the exact time when the stigma is ready to receive the influence of the pollen, and this is insured by the following beautiful contrivance of nature. At the time when the flower is closed, all the parts contain much more watery matter than after its bursting; this superfluity of water is got rid of by the pistillum absorbing it like a sponge from the surrounding parts; by degrees the anther among the rest becomes dry, and as soon as that happens an immense number of tiny springs which line the anther, having no appreciable individual force, but a considerable power when combined, begin to contract sideways, and at last pull asunder the two sides of each lobe, which give way at the line of dehiscence above referred to, and the pollen falls out, or is ejected, according to the degree of rapidity with which the springs contract. It is scarcely possible to find in all the animated world a more striking proof of the perfect design with which every part of every living object is fitted for the fulfilment of the end of its creation.

If an anther is looked at in its most usual state, it seems so different from any other organ in plants, that one would not suspect it to be what it really is, a part of a petal in disguise. But if we look at a double rose, or a double pæony, or almost any other double flower in which the stamens are changed into petals, we shall find abundant proofs that an anther is only the upper end of a petal in a contracted state; each lobe will be seen to answer to one side of the petal, and the connectivum to be the central part of the petal; or if the evidence afforded by a double, and, therefore, monstrous, flower be objected to, take a white water-lily, and you will see so insensible a transition from petals to stamens, that no one can say where the limit is between them, for many of the parts are half petals and half anthers. Botanists have numerous anatomical facts by which the real nature of anthers is further proved, but this would not be the place for an explanation of them; we can only point out to our readers the curious circumstance, that what are considered totally distinct organs, may be often shown to be nothing but other organs in masquerade. [See FILAMENT, POLLEN, STAMEN, SEXES OF PLANTS.]

ANTHOLOGY, a compound Greek word, used metaphorically, signifying a *Garland of Flowers*, viz. of poetry, and consisting of short poems on amatory, convivial, moral, funeral, monumental, descriptive, dedicatory, satirical, and humorous subjects. Their characteristic merit consists in the just expression of a single thought with

brevity and poetic beauty. The compass of a few couplets admits not of sublimity, but is well fitted to exhibit elegance without tediousness. The term *anthology* is peculiarly appropriated to a collection of Greek epigrams, taking the word not in the confined sense in which we now use it, for a pointed and witty conceit, but in the more enlarged and literal acceptation, of an *inscription*. The earliest and closest application of the term epigram was to certain short sentences inscribed on offerings in the temples. Inscriptions on buildings in general, on the statues of gods, heroes, living or dead men, next came under the denomination. They might be either in verse or prose. Their brevity, easily impressing striking events or illustrious names on the memory, recommended them also to general purposes. A moral precept, or the main bearing of a law, was embodied in this convenient form. The lover was sure to breathe out his passion in a simple strain of tenderness and gallantry. Hence, every little poem presenting one distinct idea, or insulated argument, gradually acquired the title of epigram. The largest portion of those collected in the Greek Anthology was written in honour of the dead, introducing their names and characters, or occupations; or as tributes to beauty, in gratitude for acceptance, or in complaint on account of rejection; some of them are panegyrics on living and illustrious virtue; others contain brief records of remarkable events; others again consist of observations on human life, for the most part in a dark style of colouring. The weariness of old age, the shortness and unsatisfactory tenor of human life, the murmurs of sickness, and the miseries of poverty, are favourite topics. Bacchanalian poetry is mixed up with exhortations to eat and drink, for to-morrow we die. This prevailing tendency must be ascribed to the vague notions, undefined prospects, and differently sustained hopes respecting our transition into some other state of existence by which the philosophers, poets, and ordinary men of these times were equally perplexed. But, however gloomy this view of things might be, it was compatible with a not unpleasing pathos, and raised their amatory and convivial effusions above vulgar voluptuousness, or mere festive riot.

Meleager the Syrian, whose exact date seems difficult to fix, lived probably somewhat less than a century before the Christian æra, and is generally understood to have first collected the scattered fragments of the Grecian inscriptive muse. More than one person bearing the name of Meleager has been mentioned by Diogenes Laertius and by Athenæus. but the internal evidence of two epigrams seems to determine the epoch of that Meleager to whom we owe this beautiful collection. Its interest mainly arises from its being a record of the intellectual vigour of Greece in its declining days, when her energy, whether in arms or in arts, had become less active, but had not entirely died away.

To criticize, or even to name, the host of authors comprised in this collection would be tedious; we shall barely mention the successive forms in which it re-appeared. Philip of Thessalonica continued the work about the time of Tiberius. The additional compositions were less interesting, but still pleasing. In the sixth century, Agathias collected the miscellaneous fragments of his time, and added his own contributions to the expiring muses of Greece. The bent of his own mind towards poetry seems to have been strong; in early youth he had produced a collection of amorous poems, entitled *Daphniaca*, which would have done honour to better times. He had a coadjutor in his friend Paul the Silentiary, an officer in the court of Justinian, corresponding to the modern gentleman-usher, whose topics were desultory, and his style that of the courtier and the voluptuary. From the decay of manuscripts, and the zeal of the clergy in the dark ages against all works of imagination or of gaiety, our present collection, although large, has lost many of its brightest and earliest ornaments; and it so happens, that it retains more pieces from the compilation of Agathias, than from that of his two predecessors conjointly.

In the tenth century, Constantinus Cephalas saved these manuscripts from oblivion by re-editing them. Maximus Planudes, a monk of the fourteenth century, was the last collector. His selection was marked by a want of discrimination. The first printed edition of the *Anthologia* was that of Lascaris, accompanied with some Greek verses by the editor, and a Latin epistle to Pietro de Medici. It bears the date of Florence, 1494. Claude de Saumaise, better known to the world by the Latin name of Salmasius, and to Eng-

lishmen as the antagonist of Milton, who lived in the sixteenth and the first half of the seventeenth centuries, detected the unfitness of Planudes for the duties of an editor, by the discovery, in 1606, of a MS. in the library of Heidelberg. The history of this MS. may be seen in Schoell, (iii. 42, &c.) During the eighteenth century, Suidas and the manuscripts in the public libraries of Europe were ransacked, and a valuable booty of epigrams, undiscovered or rejected by Planudes, enriched the *Analecta* of Brunck and the *Anthologia* of Jacobs. The former work, *Analecta Veterum Poetarum Græcorum*, is contained in three volumes, octavo, Strasburg, 1772-6: the latter in thirteen volumes, octavo, Leipzig, 1794-1814. Jacobs was partly led to his undertaking by the motive of excluding the extraneous matter in Brunck's edition, picked up from fragments of the minor Grecian poets, which did not come properly within the definition of an anthology: but Jacobs himself retained the lyrics and elegiacs of Simonides, the remains of Archilochus and Bacchylides, and the hymns of Proclus. The edition of Jacobs is the latest, and best. But there is much matter strictly applicable to this purpose still left unedited. There are some inscriptions, for instance, in the Elgin collection of the British Museum, that ought to be added to any future edition.

A volume of translations, chiefly from the Greek *Anthology*, was published in 1806 by Messrs. Bland and Merivale, with contributions from other gentlemen. This has been twice republished; once in 1813, with a considerable mass of extraneous and irrelevant matter in the shape of notes and illustrations, both in prose and verse; and again in 1833. In the last edition, the superfluities of the preceding one are removed, and a number of additional specimens, many of them by younger translators, are introduced: and in this state the work may be recommended as presenting a very elegant and faithful specimen of the original Greek Anthology, and one which is not likely to be surpassed. (For a full account of the editions, &c. of the Anthology, see Schoell, *Geschichte der Griech. Litt.* vol. iii.)

ANTHONY, ST., the first institutor of the monastic life, was born at a village in Upper Egypt, in the year 251. His parents, who were wealthy, are said to have prevented him, when young, from acquiring any other language than his native Coptic. Having understood some passages of our Saviour's precepts in their literal sense, he distributed the property which came to him by inheritance, at an early age, partly among his neighbours and partly to the poor; and having placed a sister who was committed to his charge in a house of virgins, retired to a solitude in the neighbourhood of his native village, where he is represented to have been tempted by the devil in a great variety of shapes. In this retirement he was reputed to have received the gift of miracles. A great number of disciples, in consequence, crowded about him, at whose importunity he erected various monasteries, where they passed their time in acts of devotion and in manual labour. He is said to have erected his first monastery at Phaium, near Aphroditopolis, about the year 305.

In 312, during the persecution under Maximinus, he went to Alexandria to encourage and give consolation to the Christians, who were suffering martyrdom; and about the same time, built a second monastery called Pispir, near the Nile.

After a long residence in the place of his first retreat, he withdrew farther from his native village, to Mount Colzum, near the Red Sea, where he made a ruined sepulchre his residence. Here also followers flocked to him, and fraternities for seclusion and mortification were formed under his example; and here he was again assailed by the devil.

Toward the close of life, about the year 355, St. Anthony again went to Alexandria, at the request of Athanasius, to defend the faith against the Arians. At this time he is said to have converted many to Christianity. Declining to accept an invitation from the Emperor Constantine to visit Constantinople, he returned to his cell, where he died in the year 356. The most antient martyrologies naming him on the 17th of January, it has been concluded that that was the day of his death.

Seven of St. Anthony's letters, written originally in Coptic, but translated into Latin, are extant in the *Bibliotheca Patrum*. His life was written by his friend St. Athanasius. St. Anthony left one of his sheep-skins, with the cloak in which he lay, to Athanasius; his other sheep-skin to the bishop Serapion; and his hair shirt to Macarius and

Amathas, two brethren, or disciples, who were with him at his death.

Among the miracles believed to have been wrought by his intercession, was the cure of the distemper called the sacred fire, since that time called St. Anthony's fire, and in modern days erysipelas. In 1095, a religious order was founded in France, called the Order of St. Anthony, the members of which were to take care of persons afflicted with this disorder.

The temptations of St. Anthony were favourite subjects with the early engravers; probably from the scope which they afforded for invention and imagination. Vasari says, that Michael Angelo, when a boy, was so struck with Schongauer's print of St. Anthony tormented by devils, (the earliest of these productions,) that he copied it in colours. (See the *Acta Sanctorum* by the Bollandists, January 17; Alban Butler's *Lives of the Saints*; Moren: and Cave's *Historia Literaria*.)

ANTHONY, ST., FALLS OF, are in the Mississippi River, in 45° N. lat., immediately above the junction of St. Peter's River. [See MISSISSIPPI.]

ANTHONY'S, ST., FIRE. [See ERYSIPELAS.]

ANTHOXANTHUM, a genus of grasses, one species of which (*A. odoratum*) is well known to farmers under the name of the *sweet vernal grass*. It is a small annual plant, bearing its flowers in short heads, which are not very compact, and broader at the bottom than the top. The floweret of which it is composed are a pale, yellowish green; each consists of two sharp-pointed, smooth glumes, within which are two other dark-brown, hairy paleæ, each having an awn at its back; the stamens are only two in number. This grass is of little importance for its nutritive qualities, but it is much esteemed for the sweet smell of its leaves, which causes much of the well-known fragrance of new-mown hay

Anthoxanthum odoratum.
a, a flower-head magnified. b, a floweret more magnified.

ANTHRACITE, a black, light, mineral substance, resembling coal; so named from *ἀνθραξ*, *anthrax*, charcoal. It is also called *blind coal*, because it burns without flame; and *glance coal*, from the German word *glanz* (lustre), because it has often a shining surface like graphite, or blacklead, as it is improperly called, the substance of which pencils are made, and to which it is very closely allied in composition. In some systems of mineralogy it is divided into *massive*, *slaty*, and *columnar* anthracite; but these are mere accidental varieties of structure, and are all of the same chemical composition, when the pure anthracite is separated from the matrix, or from the foreign matter with which it is mechanically mixed. Its specific gravity is about 1.400,

water being 1000; it is slowly combustible, but without flame, and according to the analysis by Schaub of a specimen from the Meisner, it contains 96 per cent. of pure carbon: it is, in fact, a mineral charcoal. Naphtha may be considered as one extremity of the mineral carbonaceous substances, and anthracite as the other; and from the highly-inflammable fluid naphtha, we have numerous varieties of mineral tar, or petroleum, bitumen, asphaltum, cannel coal, caking coal, slaty coal, &c., all diminishing in inflammability, until at last we come to the blind coal, or anthracite. If asphaltum, or indurated mineral pitch, be subjected to distillation, at a certain stage of the process, when it has lost a part of the bitumen which it contains, it resembles caking Newcastle coal; continuing the distillation, it passes into a substance which is identical with anthracite, both in appearance and composition. It very often happens that the coal strata in our mines are traversed by dikes of basalt; and it is a frequent occurrence in such cases, that the coal, where it comes into contact with the basalt, is converted into anthracite, often to a considerable depth, and it sometimes acquires a columnar structure. From these circumstances, geologists have drawn two inferences: first, that the basalt, when it came in contact with the coal, must have been in a melted state like lava, the heat driving off the bitumen of the coal; and, secondly, that anthracite, when found in other strata than the coal-measures, may very probably be coal altered by heat. Small quantities of anthracite are found in the primary strata of most countries, as, for instance, in the old slate of Cornwall, Devon, and Cumberland, where the appearances led to borings and other works in search of coal. It has been frequently met with in the rocks of the transition series, but it was never known to exist in rocks of that period in considerable quantity, until Mr. Weaver, three years ago, in a paper on the geology of the South of Ireland, described beds of anthracite occurring in clay-slate and grauwacke, so thick as to be regularly worked for the purpose of burning the lime of the district. He says that the most considerable collieries have yielded 25,000 tons annually, and adds, that all the coal of the province of Munster, with the exception of that of the county of Clare, is of the same sort. It is remarkable, too, that this anthracite coal, and a slate highly charged with pyrites, which accompanies it, are full of impressions of plants of the fern tribe, such as *equiseta* and *calamites*, analogous to those found in the true coal-formations; this is an important circumstance with reference to the history of anthracite, and gives strong countenance to the opinion that this substance, even in the oldest of the stratified rocks, is of vegetable origin. It is found in many of our coal-mines, but generally in those situations where the coal comes in contact with basalt. It is also met with where basalt comes into contact with carbonaceous deposits of more modern date, as at the Meisner, a mountain near Eschweg, in Hesse.

ANTHROPOGRAPHY, a term designed to express the object of one branch of physical geography.

The object of anthropography, which literally signifies *man-description*, is, to describe the actual geographical distribution of the human race; to classify it according to the varieties of physical character and language; to distinguish between nations or tribes which have the same general physical character and speak the same language, and nations or tribes which seem to belong to one stock, and have from circumstances adopted the language of another stock; to describe briefly the religious and domestic usages which constitute the basis of national character.

The term ethnography (*nation-description*) is sometimes used by German writers in the sense which we have given to anthropography; though, as far as we have observed, when so used, the word ethnography is rather more limited in its signification than that which we have assigned to anthropography. Some German writers use also the word *Völkerkunde* (people-knowledge) as an equivalent to ethnography. But ethnography has of late years been rather used to express an historical investigation into the origin and migrations and connexion of various peoples. Taking it in this sense, ethnography is purely of an historical character, and may be considered as distinct from anthropography. A series of anthropographies, of different epochs, would form the true basis of ethnography.

ANTHROPOLOGY, derived, like most of our other terms in science, from the Greek, implies the science or

theory of man. It has been little cultivated among us as a separate study, notwithstanding its obvious importance, and has never, we believe, been made the subject of an especial course at our universities. It is otherwise, however, in Germany, where various professors have read lectures on it, and subsequently published their treatises. Of these, by far the most distinguished is that of Kant, the last, and from its nature, as divested of abstruse speculation, the most popular of his works. It was published by him about the year 1798, from his text book, having been for thirty years accustomed to give a winter course of lectures on this subject, and another during the summer on physical geography, to a mixed audience, as a relief from his more severe duties as professor of pure philosophy. His observations supply the best notion of that which ought to constitute such a science, and the uses to be drawn from it, when properly executed.

A theory of the science of man, systematically executed, may either be directed to explain the phenomena and principles of our corporeal nature—and in that case it would be properly called *physiological*; or it might be calculated to furnish instruction for the cultivation and improvement of our intellectual and moral powers, and the knowledge of man, both as an individual and a species, in which case it might be termed *pragmatical anthropology*. The former, it is evident, turns on the investigation of what nature makes of man—the latter on what man, as a free agent, either makes, or can and ought to make of himself. If the cause of memory in man is assumed to be impressions left behind in the brain, he must be content to remain a mere spectator of Nature's mechanism, and can turn his observations to no account: whereas, if he applies his experience of what has been found useful or prejudicial to memory, in order to acquire greater power or facility in its exercise, the knowledge thus obtained, being formed into a system, would constitute that branch of anthropology which we have called *pragmatical*, and which it would be useful for him to cultivate.

Such an anthropology, considered as knowledge of the world, is subsequent in its cultivation to the period of academic studies; it considers man as a citizen of the world, and has nothing properly to do with the natural varieties of the human race: neither does it invade the secluded circle of what is called the great world, the individuals of which are too near to each other, and too remote from the rest of their species, to be observed with advantage. Among the best means for cultivating it, after laying in a proper store of that general information which takes precedence of all local and partial knowledge, is travel, and the reading of travels—to which may be added as aids, if not direct sources of anthropology, history, biography, the drama, and even novels and romances.

The chief obstacles to its acquirement, and attaining the rank of a science, are, in others, the unwillingness to be observed—in *ourselves*, the counter check, that while we are under any emotion, we cease to observe, and when we observe, the emotion ceases: lastly, the force of habit, which perplexes our judgment, both as to what by nature we ourselves are, and what our neighbour is.

A systematic, and yet popular anthropology, such as is described in the following outline of Kant's work, illustrated with examples accessible to all readers, is calculated to be of great utility, by affording, in the copiousness of the tabular heads under which our active qualities are arranged, so many occasions and inducements to select any one for special study and classification in its proper department. In this manner, the separate labours of individuals, and even casual contributions, would, in the unity of the plan, acquire a spontaneous distribution and progressive concentration towards a whole—thus forwarding and accelerating the growth of so useful a science.

CONTENTS.

Part I.—*Anthropological Didactic, or instructions for learning both the Interior and Exterior of Man.*

Book I. Of the Faculty of Cognition.

Of Self-consciousness.

Self-love (egoism).

Actual consciousness of our representations.

Self-observation.

Representations we have without being conscious of them.

Distinctness and indistinctness in the consciousness of our representations.

Sense in opposition to reason.

Apology for sense.

Our power in respect of the faculty of cognition in general.

Artificial play with sensuous appearance.

Allowed moral affectation (counterfeiting)

The five external senses.

The internal sense.

Causes of the increase or diminution of sensations in degree.

Obstruction, weakening, and total loss of sensation.

Sensuous inventive faculty in its different species.

Faculty of bringing the past and future before us by the imagination.

Involuntary fiction in health, *i. e.*, dream.

Faculty of design.

Faculty of cognition in as far as grounded on understanding.

Infirmities and diseases of the mind, with respect to its faculty of cognition.

Talents in the faculty of cognition—wit, sagacity, and originality or genius.

Book II. Of the Sense of Pleasure and Pain.

Of sensual pleasure.

A.—Sense for the *agreeable*, or sensual pleasure in the perception of an object.

B.—Sense for the *beautiful*, or taste.

Book III. Of the Faculty of Desire.

Of the affections (emotions).

Passions.

Highest physical good.

Highest moral-physical good.

Part II. *Anthropological Characteristic*, or the way to find out the Interior from the Exterior.

A. Of the character of the person.

1. Disposition.

2. Temperament.

3. Character of the mind (mode of thinking).
Physiognomy.

B. Character of family.

C. " of nation.

D. " of race.

E. " of species.—*Delineation of the Character of the Human Race.*

(See Kant's *Anthropologie in Pragmatischer hinsicht*. Fourth edition. Pp. 323. By J. F. Herbart. Leipzig, 1833.)

ANTHROPOPHAGI. [See CANNIBALS.]

ANTHROPOMORPHISM, a compound Greek word, literally signifying 'the representation of human form:' but it is properly used to signify the 'representation of divinity under a human form;' and the nations or sects who have followed this practice have been sometimes called *Anthropomorphites*. The Egyptians represented deities under human forms, as well as those of animals, and sometimes under a combination of the two. The ancient Persians, as Herodotus tells us, (i. 131,) adored the Supreme Being under no visible form of their own creation, but they worshipped on the tops of mountains, and sacrificed to the sun and moon, to earth, fire, water, and the winds. The Hebrews were forbidden (Exodus xx. 4, 5) to make any image or the representation of any animated being whatever.

The Greeks were essentially anthropomorphists, and could never separate the idea of superior powers from the representation of them under a human form: hence, in their mythology and in their arts, each deity had his distinguishing attributes and a characteristic human shape. Perhaps no nation has made any progress in the arts of sculpture and painting without applying their skill to the representation of deity. Thus painters in modern times have represented the Supreme Power, and our Bibles have sometimes been illustrated with engravings of this character. In one of the latest editions of the Bible (Mant and D'Oyley's), which is illustrated by engravings, the editors have omitted all representation of God, though there are earlier English editions of the Bible in which the Supreme Being is represented as a man. It might be worth while considering if some improvement could not be made even on Mant and D'Oyley as to the choice of illustrations.

Anthropomorphists is also the name of a sect of early Christians [See **HERETICS** and **SCHISMATICS**.]

ANTHUS, (Bechstein,) the Pipit, a genus of birds separated by Dr. Bechstein from the Linnæan genus *alauda*, a separation followed by Temminck, Cuvier, Lesson, and Selby, and justly, for though the pipits have a long hind claw, and are usually coloured, like the larks, their bill is more slender, in consequence of which they never, like them, feed on grain. In the form of the head, in the movement of the tail, and their mode of life, they resemble the wag-tails (*Motacilla*) on the one hand, and on the other the blue-breast (*Sylvia Suecica*).

Adhering, then, to the distinction of Bechstein, we characterize pipits by the bill being straight, slender, somewhat awl-shaped towards the point, having the base of the upper mandible keeled, the tip slightly bent downwards, and notched. The nostrils, situated at the sides of the base of the bill, are oval, and partly concealed by a membrane. Feet, with the shank (*tarsus*) generally exceeding the middle toe in length; toes, three before and one behind, and with the outer toe adhering to the middle one as far as the first joint; the hind claw rather long. The wings have the first quill very short; the third and fourth the longest in each wing.

We shall give particular details of each species under *Pipit*.

ANTIARIS is the botanical name of the half-fabulous upas-tree, of which so many idle stories were propagated some years since by travellers. It was said to be a large tree, growing in the island of Java, in the midst of a desert caused by its own pestiferous qualities; its exhalations were reported to be so unwholesome, that not only did they cause death to all animals which approached the tree, but even destroyed vegetation for a considerable distance round it; and, finally, the juice which flowed from its stem, when wounded, was said to be the most deadly of poisons. To approach the upas-tree, even for the momentary purpose of wounding its stem and carrying away the juice, was stated to be so dangerous, that none but criminals under sentence of death could be found to undertake the task. As is usual in such cases, this fable is founded upon certain natural phenomena which occur in Java. There is such a tree as the upas, and its juice, if mixed with the blood in the body of any animal, is speedily fatal; and there is also a tract of land in the same island on which neither animal nor plant can exist. But the two circumstances have no relation to each other: the poisoned tract is a small valley completely surrounded by a steep embankment, like the crater of a volcano, and is continually emitting from its surface carbonic acid gas, which is alike fatal to animals and plants; on the other hand, the poisonous upas-tree is not an inhabitant of the valley, for nothing can live there, but it flourishes in the woods, in the midst of other trees which are unharmed by its vicinity. (For particulars concerning this fable, see

Antiaris macrophylla (a diminished figure).

1. a head of male flowers in the involucre; 2. the same divided perpendicularly; 3. a couple of the male flowers; 4. a pistil; 5. the same divided perpendicularly; 6. a fruit.

Darwin's *Botanic Garden*, and the *Penny Magazine*, vol. ii., p. 322; for an account of the Valley, consult the *Journal of the Geographical Society*, vol. ii., p. 60.)

In the eye of a botanist, the upas is a species of the genus *Antiaris*, which belongs to the natural order *Artocarpeæ*, a group of plants all of which abound in a milky juice, and many of which are extremely poisonous. (See *ARTOCARPEÆ*.) Of the original species, *A. toxicaria*, we have met with no scientific figure; it is, however, cultivated in the botanical garden, Calcutta, whence we have a leaf or two. They are very much like those of the following plant, *A. macrophylla*, which has been found on the north coast of New Holland.

The genus *Antiaris* has its stamens and pistilla in separate flowers. The former are collected in little heads in the centre of a minute three or four-leaved calyx, of which a considerable number is inclosed in a hairy involucre formed of several fleshy divisions, which are rolled inwards. The pistillum is surmounted by a calyx of several leaves, terminating in a long, two-parted style, and contains a single suspended ovulum. The pistilla and the antheriferous flower-heads stand in pairs, side by side, in the axillæ of the leaves.

ANTIBES, a fortified town and port of France, on the Mediterranean, in the department of the Var, very near the frontier of the Sardinian dominions, 587 miles S.E. by S. of Paris, and about 19 miles S.W. of Nice, 40° 33' N. lat., 7° 7' E. long. from Greenwich.

It is a place of great antiquity, having been founded by the Greeks who had settled at Massalia, now Marseilles, as a barrier against the incursions of the Salyes, and the Ligurians who inhabited the Alps. (Strabo, p. 180.) Some accounts state that the Marseillois took it from a tribe of Ligurians; but however this may be, the place probably owed its importance, as well as its name, (*Ἀντιπολις*, Antipolis,) to the Greeks. It was taken from under the jurisdiction of Marseilles, and placed in the rank of an Italic city (Strabo) in the time of Augustus; and appears to have been a flourishing place, to which the tunny fishery may have contributed. The remains of a theatre and some other antient buildings attest its former importance. During the Roman dominion there was an arsenal, and the town was protected by fortifications, of which two strong towers yet remain. After the downfall of the Roman empire, Antibes became subject to successive nations of barbarians, Visigoths, Ostrogoths, and Franks. It was destroyed by the Saracens in the ninth century, rebuilt and repeopled in the tenth, and again plundered by Spanish and Moorish pirates. In 1746, it stood a siege against the Austrians, aided by England and Savoy. It signalized itself in 1815, by shutting its gates against Napoleon on his return from Elba.

It is built on the eastern side of a small peninsula, dividing the gulf of Juan from that into which the Var falls; in a district fertile in wine and fruits, especially oranges, but little productive of the other necessaries of life. The harbour, which is nearly circular, is so choked up with the sand brought by the Var, the mouth of which is only a few miles distant, that, in all the extent of the basin, there is only a space of less than 300 feet by 950 feet where vessels can anchor; and to approach the mole they must not draw above fifteen feet of water. The trade of Antibes, which is but small, is chiefly in oil, olives, dried fruits, and especially salt fish. The inhabitants, who amount to about 5000, are considered very skilful in preparing anchovies.

Antibes is a place of considerable strength, though not in the first class of fortresses. There is a citadel and several batteries and forts for the protection of the harbour. The fortifications appear to have been erected in the times of Francis I. and Henry IV., and improved by Vauban in the days of Louis XIV. Their erection has served to drain the surrounding marshes, and render the air healthy. (*Encyclopédie Méthodique*; *Dict. de la France*; M. Brun; Balbi.)

ANTICHRIST (*Ἀντίχριστος*) means, literally, the opponent of the anointed, or of the Messiah. The name of Antichrist (*אנתקריסטוס*) was given by Jews and Christians to the great enemy of true religion, who shall, according to the Holy Scriptures, appear before the coming of the Messiah in glory. The general woe effected by Antichrist is called by the Jews *הבלי משיח* or *the pangs of the birth of the Messiah*.

The name of Antichrist occurs in the New Testament only in the first two epistles of St. John: 1 Epist. ii. 18. 22;

iv. 3; 2 Epist. 7. In some of these passages false teachers are called Antichrists, and every spirit that confesseth not that Jesus Christ is come in the flesh is not of God: and this is that spirit of Antichrist, whereof ye have heard that it should come; and even now already is in the world. St. Paul calls Antichrist that *man of sin*, the son of perdition; who opposeth and exalteth himself above all that is called God, or that is worshipped; so that he sitteth in the temple of God, showing himself that he is God. That wicked whom the Lord shall consume with the spirit of his mouth, and shall destroy with the brightness of his coming: whose coming is after the working of Satan, with all power and signs and lying wonders. 2 Thess. ii. Emblematical descriptions of Antichrist occur in the twelfth and thirteenth chapters of the Revelations. One of the newest German novels bears the title *Antichrist*.

ANTICOSTI, an island lying in the mouth of the river St. Lawrence, between 49° 5', and 49° 55' N. lat., and between 61° 54', and 64° 30' W. long.

This island does not possess a single harbour. Its shore on the north side is high, and the water close to the cliff is deep; on the south the land is low, and the water shoal. Some rocky reefs extend to a considerable distance from the shore, and are the cause of numerous shipwrecks. The island is uninhabited, with the exception of two families who have been established here by the governor of Newfoundland, one at the east, the other at the west end, for the purpose of giving help to persons cast away upon the coast. The surface is covered with white cedar, birch, fir, poplar, and dwarf spruce trees, all of which are stunted in their growth. Bears, foxes, hares, and sables are numerous, as well as partridges, curlews, plovers, and snipes. The interior has never been explored by Europeans. Such Indians as have visited it in search of game describe it as being mostly swampy.

The Indian name of this island is Natiscooti, of which its present name is evidently a corruption. It is included within the government of the Island of Newfoundland. (Anspach's *History of Newfoundland*; M'Gregor's *British America*.)

ANTIDICOMARIANITES. [See **HERETICS**.]

ANTIDOTES, from two Greek words, signifying, *given against*; the means of counteracting the effects of poisons. The term *antidote* had formerly a much wider signification, and was applied to the remedies for diseases occurring from natural causes, as well as to the remedies for the derangements of the functions arising from the direct introduction into the system of a known and material poison. Doubtless every disease may be looked upon as springing from some poison; as fevers from an altered and unhealthy state of the atmosphere; or eruptive and contagious diseases from the vitiated fluids or breath of one individual communicated to another, as small-pox, and hooping-cough. This opinion is expressed by the employment of the term *virus*, or *poison*, to signify the immediate cause of such diseases; as when we speak of the small-pox virus, or the vaccine virus.

But as, in the present day, the word *antidote* is used only to signify the means of counteracting the effects of poisons, strictly so called, we shall confine our observations to what is properly comprehended under the term, when employed in this sense. While thus limiting its signification, it is equally necessary that we should limit the application of the word *poison*. It is, however, extremely difficult to define what a poison is. Foderé considers poisons to be 'those substances known to be capable of rapidly altering or destroying some or all of the functions necessary to life.' This must be understood to apply to their introduction (whether accidentally, intentionally on the part of the person suffering, or criminally on the part of others) into the body when in the usual state of health; for there are certain diseased conditions of the system, which seem to render it incapable of being injuriously affected by doses of medicines which at another time would speedily destroy life; and other states, such as when the body is under the influence of one poison, where another proves the most effectual remedy or antidote. This latter state is strikingly exemplified in the case of the bite of the *Coluber carinatus*, a species of snake common in the West Indies, during the state of stupor or insensibility occasioned by which, a large quantity of arsenic may be given, not only with safety, but with such advantage that the recovery of the patient may be considered as owing solely to it.

To acquire a correct idea of the different ways in which

poisons operate in destroying life, we must be made aware that what we commonly regard as an *individual*, is made up of a number of distinct organs, which, though in some respects independent of each other, yet exert a reciprocal influence, the harmonious play of the whole being necessary to the continuous exercise or display of the principle of life, and that a cessation of the functions of any one of the more important organs necessitates the successive suspension of the rest. The most essential of these are consequently denominated the *vital functions*, viz., the circulation, respiration, and innervation. The circulation of red or *arterial* blood through the system, but especially through the nervous matter of the brain and spinal chord, is essential to the existence of the vital properties, and due performance of the functions, of the different organs—which circulation is effected by the action of the *heart*,—while, to render the blood arterial, respiration is necessary, and this is effected by the *lungs*, assisted by a great number of muscles, the co-operation, or simultaneous action of which, is occasioned by the influence of the *spinal chord*, directed or influenced by the *brain*. Now, certain poisons act either solely on one of these organs and functions, or upon two or three, but always in an ascertained order or uniform succession. Oxalic acid, (or the acid of sugar, as it is popularly called,) for example, in a small dose, acts first on the brain and spinal chord, but in a larger dose, also affects the heart: in the former case, the respiration will be perceptibly interfered with, while the heart will go on acting for some time; in the latter case, both will cease at the same moment. Recovery, therefore, is much more probable in the first instance than in the second: for we can carry on *artificial* respiration till the brain and spinal chord have resumed the exercise of their functions; but if, as in the second instance, the heart also has ceased to act, recovery is impossible.

An arrangement of poisons according to their mode of action, i. e. according to the order in which the vital functions are successively affected and destroyed by them, would be of great utility in regulating our treatment, teaching us when to be content with the employment of antidotes alone, and when to employ supplementary means,—as artificial respiration, blood-letting, &c. At present we can only make an approximation to such an arrangement.

Another point of consequence is the settlement of the question,—Do poisons act solely on the sentient extremities of the nerves of the part to which they are applied, and influence remote organs, only by sympathy, or are they absorbed into the circulating fluids, and by them carried to the organs, whose impaired or suspended functions show them to be markedly affected by them? Without entering into this dispute, it may be stated that some poisons act in the one way, some in the other way, and a few in both. Of these, the first set are the most formidable and the most speedy in their action, allowing little time for the employment of antidotes.

Some poisons act, but with different degrees of violence and speed, whatever part of the body they are applied to; others, again, only when received into the stomach or intestines; while some, such as the poison of the viper, are quite powerless when swallowed. Of all parts of the body, the brain and nervous substance are the least susceptible of the action of poisons, when applied directly to them, though acted upon by so many poisons when applied elsewhere.

With respect to the local operation of poisons, i. e. their direct action on the part to which they are applied, some decompose chemically, or alter the structure of (corrode) the part which they touch, and hence they are called *corrosive* poisons; such are the mineral acids, of which sulphuric, or oil of vitriol may serve as an example. Besides this local effect, many of the corrosive poisons act speedily upon remote organs, the impaired function of which may become a source of greater danger than the destruction of the part first attacked.

Other poisons, without immediately altering the structure of the part, irritate it so that inflammation ensues, by which it is altered, and the general system affected, as it would be by inflammation of the same part arising from any other cause—even when the poisonous substance does not produce any immediate or powerful effect upon a remote organ—which is not often the case, as most of them influence some of the vital functions, and thus prove fatal. These are termed *irritant* poisons, such as arsenic; but they are frequently also termed *corrosives*, though inaccurately.

Lastly, there are poisons which neither corrode nor irritate the part, but cause a peculiar impression upon the sentient extremities of the nerves, which is conveyed along these to some remote organ or organs, the function of which they impair or suspend. Many of these should be termed *sedatives*, in the strictest sense of the word [see *SEDATIVES*]; others are *narcotics*; and those which produce some degree of local irritation, are termed *narcotico-acrids*. But often one and the same article, according to the dose and mode of administration, acts in all the three ways; tobacco for example.

The selection of appropriate means to counteract the effects of poisons must be determined by a knowledge of the manner in which each particular poison acts; but as we cannot enumerate or specify these here, we shall give only general rules to this effect. These may be reduced to three, viz., 1, to remove the poisonous substance; 2, to prevent or limit its local effects; 3, to obviate its effects on remote organs, supporting their action by appropriate measures, till the injurious impression has subsided. The first of these is to be accomplished mostly by mechanical means. If the poison has been applied to any external part, as by the bite of a viper, or rattle-snake, a cupping-glass, or what will answer as well, a wine-glass, tumbler, or cup of any kind, from which a part of the air has been expelled, by holding within it a lighted candle for a second of time, should be immediately applied. If the poison has been taken into the stomach, and is not of a kind to arrest instantly the action of the heart, its removal is to be attempted by the stomach-pump, or by exciting vomiting. The stomach-pump cannot well be used without introducing into the stomach a considerable quantity of water, which, by diluting the poison, lessens its violence, in all cases, except that of oxalic acid. The stomach-pump is also to be preferred in the case of narcotic poisons, as the insensibility which they occasion prevents the stomach from being affected by emetics. But should a stomach-pump not be at hand, nor any one be present skilled in the use of it, we must attempt to produce vomiting by every means in our power. For this purpose, a table-spoonful of flour of mustard, which is mostly to be found in every house, may be put into a tumbler of warm water, and given to the patient; or a scruple of sulphate of zinc (white vitriol) dissolved in a pint of distilled water; or ten grains of sulphate of copper dissolved in half a pint of any distilled water, as cinnamon, may be drunk by the patient, and the disposition to vomit encouraged by tickling the throat with a feather, and pressing on the pit of the stomach. Neither ipecacuanha nor tartar emetic should be given, as their action is always preceded by much nausea, during which the absorption of the poison is often facilitated.

Where the poison is of a corrosive or irritant nature, instead of losing time in seeking the means of causing vomiting, it is in general advisable to adopt the second rule, and attempt to prevent or limit its local, and thereby its remote, effects. To accomplish this, we must ascertain what the poisonous substance was from which the patient is suffering, and must also know how it acts, as upon this depends the success of our treatment. The objects we must have in view are either to dilute, and so weaken it; to supply from an external source the particular principle, which the poison would abstract from the coats of the stomach; or by adding something to it, so change its nature as to render it comparatively or altogether harmless, which last will always be effected if we can succeed in forming an insoluble compound. The first may be done by giving plenty of warm water; and when we know the particular poison, if the warm water can be made the vehicle of an antidote, the second or third object will also be ensured. Suppose sulphuric acid (oil of vitriol) has been swallowed, add to the water, chalk, magnesia, or soap: the chalk will make, with the acid, sulphate of lime, which being insoluble, will do no harm, while with the magnesia the acid will form sulphate of magnesia (Epsom salts), and with the soap sulphate of potash, both of which are purgative salts, and will, by their action on the bowels, assist in lessening the inflammation caused by the poison before it was decomposed. So when sugar of lead (acetate of lead) is swallowed, by giving Epsom salts we form an insoluble sulphate of lead, which will be discharged by the bowels, operated upon by the magnesia, which has been freed from the sulphuric acid. Corrosive sublimate (bi-chloride) of mercury abstracts from the coats of the stomach the albumen which they contain, by which it is converted into prot.

chloride, or calomel; now, if by giving white of egg, which is pure albumen, we supply it with the principle which it would otherwise obtain from the coats of the stomach, we shall preserve these entire.

Such means, then, are antidotes, properly speaking; for the means by which the secondary or remote effects are to be combated, deserve rather to be termed counter-poisons. The counter-poisons are of no small value in cases of poisoning by the corrosive and irritant, while they are of the utmost importance in the treatment of the sedative and narcotic poisons. To administer these appropriately, we must know which of the vital organs the poison most speedily affects. When it affects the heart, the symptoms greatly resemble syncope (or fainting), and as such poisons are the most dangerous, agents which act as rapidly as the poisons are alone to be trusted to: such agents are to be found among the diffusible stimuli, ammonia, or its carbonate, *i. e.* smelling salts, applied to the nostrils, or dissolved in water and taken into the stomach, warm brandy and water, &c. Where it chiefly affects the spinal marrow, there occur spasms and difficulty of breathing; and when the brain, there is partial or complete insensibility (coma), often with, at first, full pulse, flushed face, and laborious breathing, resembling apoplexy. In such a state of affairs, artificial respiration, and afterwards bleeding, with the subsequent administration of coffee or vinegar, greatly contribute to save the patient.

We have not spoken here of gaseous poisons, which would lead to unnecessary details. They act either by excluding the common atmospheric air, in which case removal into pure air is required; or by producing inflammation, like the irritant, or oppression of the brain, like the narcotic poisons, and are to be combated on similar principles. It will be more useful to append a list of the poisons which act on the brain, and of those which act on the heart. Of poisons which act upon the brain, the most common are alcohol, *i. e.* spirituous liquors, opium, henbane, hemlock, camphor, and the essential oil of almonds, and of tobacco. Of those acting on the heart, the chief are, infusion of tobacco, and large doses of prussic acid, foxglove, strychnia (principle of nux vomica), oxalic acid, arsenic, preparations or salts of antimony and of baryta, and several animal poisons.

From what has been said on this subject, the great necessity of an acquaintance with it must be sufficiently clear, not only to insure our doing right, but to prevent us from doing wrong. By administering an ill-timed antidote (as we conceive it to be), we often hasten the fatal event: as where vinegar is given when opium has been swallowed, before it has been ejected from the stomach; and by throwing tobacco smoke into the bowels of a person apparently drowned, we extinguish the feeble spark of life which might have sufficed to reanimate him but for such injudicious interference.

It is to be hoped that more just principles of treatment will be diffused among the people, as well as among medical men, by which many lives may be preserved to their families and to the community. [See POISONS.]

Silver Coin, British Museum.

ANTI'GONUS, one of the officers of Alexander the Great, a Macedonian by birth, who took a leading part in the scramble for kingdoms which ensued among that prince's generals after his death, *a.c.* 323. From that time till his own death, *a.c.* 301, the history of Antigonus is in great measure the political history of western Asia. It comprises a long and intricate series of wars, in which extensive provinces rapidly changed their masters; but it is chiefly interesting as connecting the rise of the two great dynasties of the Ptolemies and the Seleucids with the establishment of the Macedonian empire in the east.

For the immediate consequences of Alexander's death, we refer to **ANTIPATER** and **PERDICCAS**. In the general distribution of provinces, or satrapies, to the chief Macedonian officers, Antigonus received the greater Phrygia, Lycia, and Pamphylia. But as soon as Perdicas conceived the project of rendering himself the real master of all the Macedonian conquests, he sought the ruin of Antigonus, as the most likely person to thwart his views. Antigonus saw his danger, and fled with his young son, Demetrius, to Antipater. It does not appear that he took an active part in the short contest which ensued between the European and the Asiatic chieftain: but Antipater, on making a fresh distribution of the Asiatic provinces, added Susiana to Phrygia and Lycia, which Antigonus already held, (we find no mention of Pamphylia in the second division,) and declared him general of the king's forces in Asia, with a special commission to prosecute the war against Eumenes, one of Alexander's best officers, satrap of Paphlagonia and Cappadocia, who had espoused the party of Perdicas, and still refused to acknowledge Antipater as protector. Antigonus gained a victory over him by bribing one of his chief officers to desert in the hour of battle. Eumenes, unable to keep the field, shut himself up in the strong fortress of Nora; and his antagonist, after drawing lines of circumvallation round him, and leaving a sufficient force to maintain the blockade, marched into Pisidia, and soon overthrew Alcetas, the brother, and Attalus, the brother-in-law of Perdicas, the only persons except Eumenes now openly hostile to Antipater.

There is some difficulty in settling the chronology of this period, since Diodorus, as our copies now stand, passes at once from *a.c.* 322 to 319, omitting to mark the intervening years. But the expedition of Antigonus against Alcetas is placed by him in the latter half of 319; and his arrival in Macedonia may be determined to the beginning of 321, in which year Perdicas died. If therefore we suppose that the winter of 321-20 was spent in arranging affairs upon Antipater's accession to the regency, and that Antigonus commenced his operations against Eumenes in 320, two years will be left for those operations, for the proceedings against Alcetas and Attalus, and for the siege of Nora, which ended after the death of Antipater, and therefore in the course of 318. This seems more time than these transactions require.

Antigonus, on hearing of the death of Antipater, began to attempt the establishment of an independent kingdom in Asia. For this undertaking he was qualified, not only by his talents and skill in war, in which he was inferior to none of the generals trained under Philip and Alexander, but also by the possession of four provinces and a powerful army of 60,000 foot, 10,000 horse, and 30 elephants, and by the commission of the late regent Antipater, constituting him general of the royal forces. This, in the unsettled state of affairs, might be considered almost as good a warrant as any derived from the son of Alexander by Roxana, who, under the tutelage of his grandmother Olympias, had now nominally succeeded Arrhidæus on the Macedonian throne. Considering it of high consequence to gain over Eumenes, he sent the most flattering invitations to that general, while still cooped up in Nora; and Eumenes so far assented to his terms as to take an oath of fidelity to him, conjointly with Olympias and the children of Alexander. Meanwhile he expelled the satraps of Lydia and Hellespontine Phrygia, or Mysia, from their provinces, and took possession of Ephesus, and of four ships laden with 600 talents of silver, on their way to Macedonia.

The state of things in Europe favoured his views. Cassander, son of Antipater, dissatisfied with the inferior station assigned to him by his father, sought, by the assistance of Antigonus, to supplant Polysperchon, and obtain the protectorate. This Antigonus readily promised, hoping that, while the attention of the government at home was distracted by these contests, he should easily establish his own power in Asia. But he found a formidable enemy in Eumenes, who was no sooner at large than a considerable body of his Cappadocian friends and followers collected round him; and receiving from Olympias and Polysperchon a large sum of money, with the command of 3000 of the Argaspidae, or Silver-shields, a select body of Macedonian veterans, with the commission of imperial general in all Asia, he declared himself openly in support of the royal authority. He soon collected a strong army; but, unable to make head against Antigonus, he retreated through Cilicia and Cœle-Syria into Babylonia, where he wintered in 317-6,

The following summer was spent by the contending generals in a series of marches in Persia and Media: Antigonos being supported by Python, satrap of Media, and Seleucus, satrap of Babylonia; Eumenes by the satraps of the upper provinces, as they were called, lying to the north, and towards India, who were united by a common fear of Python. After a doubtful campaign, closed by an indecisive battle, in which the fortune of war preponderated on the whole against Antigonos, the armies separated; Antigonos taking up his winter quarters at Gamarga, or Gadama, in Media, Eumenes in Gabiene. A district of nine days' journey separated the two. Crossing this by a forced march in mid-winter, Antigonos endeavoured to surprise the enemy; but his wary adversary was not off his guard. A pitched battle ensued, which in the critical moment was lost by the cowardice or treachery of one of Eumenes' officers, and on the next day that brave and faithful general was delivered up bound to Antigonos by the Argyraspidæ. This completed the ruin of the royal party in Asia, which Eumenes alone upheld. (B.C. 315, early.)

Antigonos returned to Media, and went into winter-quarters near Ecbatana. He made a savage use of his victory, putting to death several officers whom he knew to be ill affected towards himself. Eumenes he retained some time in prison, earnestly desiring to secure his services; but finally apprehension, or the importunity of his Macedonian followers, prevailed on him to consent to that great general's death. His friends now began to experience how much more ambition weighed with him than gratitude. Python, satrap of Media, was sacrificed to his jealousy, another of the best and bravest of Alexander's officers. On quitting Media, he directed his march towards Susa; the citadel of which containing treasures stored there by Alexander, to the amount of 15,000 talents, was delivered up to him by order of Seleucus; in addition to which he had amassed 10,000 talents in gifts and valuable booty in Media and elsewhere. Returning towards the Mediterranean through Babylonia, he took occasion to quarrel with Seleucus, of whom he required an account of the revenues of his province. The Babylonian satrap declined to render it, alleging that he held the government as a free gift from the Macedonians, on account of his services during the life of Alexander; and indeed his title, and that of Antigonos, to their respective dominions, stood on the same ground. But finding that his dangerous ally would by no means admit this answer, and warned by the fate of Python, Seleucus fled betimes to Egypt: seeking to engage Ptolemy in a combination against Antigonos, who now aimed openly at uniting all the Macedonian conquests under himself.

Cassander, and Lysimachus, governor of Thrace, readily joined with Ptolemy and Seleucus to check the power of their dangerous rival; and in concert they sent demands which they could not expect to be granted, requiring him to resign Cappadocia and Lycia to Cassander, Hellespontine Phrygia to Lysimachus, Syria to Ptolemy, and Babylonia to Seleucus; and to divide with them the ample treasures which he had acquired in the war against Eumenes. Antigonos replied by menaces against Ptolemy, and prepared for the struggle. He sent ambassadors to gain Rhodes and Cyprus to his party, and dispatched Aristodemus the Milesian into Peloponnesus to raise soldiers, and cultivate the friendship of Polysperchon; who, having lately been the common enemy of Cassander and himself, was now united to him by their common jealousy of Cassander. Aristodemus succeeded in both his objects. Meanwhile Antigonos had been diligently employed in Phœnicia in building ships, the chief naval power of the Mediterranean being in the hands of his enemies. It is said by Diodorus that 8000 men were employed in felling and sawing timber in Mount Libanus: and Antigonos boldly declared, that before the summer was over, (B.C. 314,) he would command the sea with a fleet of 500 vessels. In that summer, the Rhodian fleet in his service had been defeated by Ptolemy's lieutenant on the coast of Cilicia; but this misfortune was more than counterbalanced by his success in Syria, where the strong cities of Joppa, Gaza, and Tyre fell into his hands. He then left his son Demetrius, surnamed Poliorcetes, or Taker of Cities, a young man of high promise, to command in Syria, and himself repaired to the western coast of Asia, in the winter of 314-3. During the next year, the greater part of Caria fell into his hands, and he was further occupied in exciting the Thracian tribes to annoy Lysimachus, and in forming a party in Greece against

Cassander. In that, and in the following year, most of Peloponnesus, Eubœa, Thebes, and the greater part of Phocis and Locris, were gained to his alliance; and a prudent appearance of moderation in re-establishing, as independent states, the cities from which he expelled Cassander's garrisons, added greatly to the good feeling entertained towards him. These successes, however, were clouded by the ill-fortune of Demetrius, who was defeated by Ptolemy in a great battle at Gaza, in consequence of which the coast of Syria, as far as Sidon, returned into the victor's possession (B.C. 312, after midsummer). Seleucus, encouraged by this success of his ally, and trusting to his popularity among his former subjects, returned to Babylonia with only 2000 followers, and with that small force regained possession of his satrapy. From this time the æra of the Seleucidæ commences. The fortunes of Antigonos were restored, partly by a victory gained by Demetrius over one of Ptolemy's lieutenants, and partly by his own return to Syria, upon which Ptolemy, unwilling to risk all in a pitched battle against so able a general supported by a superior army, fell back into Egypt. Antigonos then employed his son in a fruitless attempt to take Petra, the chief city of the Nabathæan Arabs. This place, of which a very curious and interesting account has been published by Captains Irby and Mangles, lies about fifty miles in a south-westerly direction from the southern end of the Dead Sea, and was then a caravan station and a great dépôt of Arabian merchandise: the hope of plunder seems to have been the chief object of the enterprise. Demetrius failed in this project, and also in an attempt to expel Seleucus from Babylonia, B.C. 311. A peace was concluded between Cassander, Lysimachus, and Ptolemy, on the one part, and Antigonos on the other, upon condition that Cassander should be president (*συνεργός*) of Europe until the nominal king, Alexander, son of Alexander the Great by Roxana, attained his majority; and that the other parties should remain in possession of what they each had; and that the Grecian cities should be free.

We may here briefly trace the history of the royal family of Macedon up to this time. After Antipater's death, Polysperchon brought forward Alexander, the son of Roxana, supported by Olympias, as a rival to Arrhidæus. Arrhidæus fell into the hands of Olympias, who put him to death, B.C. 317. In the following year, Olympias being taken prisoner, together with Roxana and her son, suffered the same fate at the hands of Cassander, who retained the young king and his mother in close custody. On the conclusion of this peace he added the murder of them both to the long list of flagrant iniquities which pollute this history, moved partly by the fear that the Macedonians would be inclined to favour the cause of Alexander's son, partly by the desire of obtaining that article which provided that his own government should expire when the young prince came of age. Two only of the descendants of Philip now remained. Hercules, the son of Alexander by Barsine, (see ALEXANDER,) was brought forward by Polysperchon as a claimant to the crown; but he, treacherous guardian was bribed to murder him by Cassander (B.C. 309). Somewhat later, Cleopatra, Alexander's sister, having engaged herself in marriage to Ptolemy was secretly poisoned by Antigonos, who durst neither detain her forcibly at Sardes, her place of residence, nor was willing to let her go to Egypt, to strengthen Ptolemy by her claim to the succession. Thus was the house of Philip and Alexander cut off root and branch, not reaching even to the fourth generation. 'and it was extinguished by the hands of such as thought upon nothing less than the execution of God's justice, due unto the cruelty of these powerful, but merciless, princes. Wherefore the ambitious frames, erected by these tyrants upon so wicked foundations of innocent blood, were soon after cast down, overwhelming themselves or their children with the ruins, as the sequel will declare.' (Raleigh, *History of the World*.)

To return to the order of events: the alliance did not last more than a year, and Ptolemy was the first openly to break it, alleging that Antigonos had transgressed the conditions by interfering with the Grecian cities. During the years 310, 309, 308, hostilities continued, without any marked events, but somewhat to the disadvantage of Ptolemy. In June, 307, Demetrius, being sent to Greece by his father with a powerful fleet to set free the Grecian cities who were still held by Cassander, appeared before the Piræus and having made himself master of that important place was gladly entertained as a friend by the Athenians, whom he guaranteed the independence of their state.

He completed their deliverance by besieging and demolishing the fortified port and suburb of Munychia, which the Macedonians had used as a citadel to hold Athens in subjection. He thus restored the democracy, fifteen years after it had been put down by Antipater, at the end of the Lamian war. Extravagant honours were paid to him and to Antigonus on this occasion. Gilded statues were erected to them near those of Harmodius and Aristogiton; golden crowns were voted to them; they were worshipped as deities; and two new wards were added to the ten existing ones, and called after their names. Demetrius also took Megara, which was held by Cassander; but he was hastily recalled to Asia, to make head against Ptolemy. He gained all Cyprus to his father's cause, first defeating Ptolemy's lieutenant by land, and then Ptolemy himself, who came with a great fleet to relieve the island, by sea, B.C. 306. On hearing of this great success, which was expected to bring forth more important consequences than the event proved, Antigonus assumed the diadem, the ensign of regal dignity in Persia, with the title of king, and his example was followed by Ptolemy, Lysimachus, Seleucus, and Cassander. In this year, Antigonus founded the city of Antigonía, in Syria, on the river Orontes. [See ANTIOCHIA.]

In the following year, 305, Antigonus invaded Egypt with a powerful army both by land and sea, the fleet being commanded by Demetrius. But the mouths of the Nile were so strongly fortified, that no entrance could be forced by sea; the army could do nothing without the co-operation of the fleet; and Antigonus was obliged to return to Syria, with some loss, and no glory. In 304 he turned against Rhodes, which, after flourishing in a neutral state for several years, now found itself obliged to embrace his cause, or to defend itself by arms. The Rhodians resisted bravely, and though pressed by Demetrius with his utmost skill and vigour, held out for a year; at the end of which Antigonus required his son to make peace on the best terms he could with the besieged, and repair to Greece, where Cassander, during his absence, had regained much power. Demetrius found no difficulty in replacing things on their former footing. Cassander was driven beyond Thermopylæ (B.C. 303), his garrisons were expelled from Sicyon, Corinth, and other important places, and Demetrius assembled a general council at the Isthmus, at which he was chosen captain-general of Greece. Cassander, alarmed at the turn which things were taking, endeavoured to conclude peace with Antigonus; but failing in this, he engaged Lysimachus, Ptolemy and Seleucus, who felt that if Antigonus should gain possession of Macedonia, their own safety would be endangered, to make a diversion by invading Asia Minor. This was done by Lysimachus, B.C. 302. Antigonus hastened to meet him, but could not force him to battle; and on the approach of winter, and the arrival of Seleucus from Upper Asia, the three kings went into winter quarters. In the spring, Antigonus recalled Demetrius from Greece. About August 301, the armies met at Ipsus, in Phrygia; they were well matched both in number and in the qualities of their generals, of whom Lysimachus, Seleucus, and Antigonus, had all acquired experience and fame under Alexander, while Demetrius, though young, had gained high reputation in his varied services by sea and land. Antigonus had about 70,000 foot, 10,000 horse, and 75 elephants. The allied kings mustered 64,000 foot, 10,500 horse, with 400 elephants, and 120 armed chariots. Antigonus, grown old in arms and success, and commonly most cheerful before the hour of battle, is said on this occasion to have been haunted by apprehensions of misfortune. The battle was lost, owing in part to the impetuosity of Demetrius, who charged and routed Antiochus, the son of Seleucus; and pursuing him too eagerly, gave opportunity to Seleucus to interpose his elephants and cavalry between his own victorious division and the main body of his father's army. Antigonus fought bravely to the last, replying to those who counselled him to fly, 'Demetrius will come and help me.' He was slain, his army was routed, and Demetrius fled into Greece.

Thus perished Antigonus, at the age of 81, leaving the character of a brave, able, and successful soldier, a faithless, merciless, insatiable, and insolent man. His best qualities were to be found in the private relations of life, especially in his cordial affection and full confidence towards his heir Demetrius. The empire, which he had spent so much labour and blood to consolidate, was divided among the victors [see SELEUCUS], and his son, after experiencing

many revolutions of fortune, died in captivity. The fortunes of the house were partially revived in

ANTI'GONUS GONATAS, so named from being born at Goni, or Gonnos (Strab. p. 440.), in Thessaly, son of Demetrius Poliorcetes. After the death of his father, there were various claimants to the Macedonian throne, which was finally seized by Ptolemy Ceraunus, to the exclusion of Antigonus (B.C. 281). Ceraunus was slain in battle against the Gauls. After the great overthrow of the barbarians in Thessaly, Antigonus defeated another division of them in Macedonia, and soon after gained possession of his paternal kingdom, B.C. 277, in spite of the opposition of Antiochus; whose sister, Phila, he soon after married. He was driven out of Macedonia by the celebrated Pyrrhus, king of Epirus, in 272, and fled into Peloponnesus, where, like his father, he possessed a powerful interest. On the death of Pyrrhus before Argos, in 271, he recovered Macedonia; but was again expelled by Alexander, son of Pyrrhus, and reinstated by his own son Demetrius. During the latter part of his life, he held his own dominions in peace; but he was continually employed in extending his influence in Peloponnesus, both by force and fraud, and was brought into frequent collision with the Achæan league. [See ARATUS.] He died B.C. 243, or 239 (Clinton), leaving a son, Demetrius II., who reigned ten years.

ANTI'GONUS DOSON (about to give), so named, because his promises were more ready than his performance, is said to have been the son of a Demetrius, who was the son of Demetrius Poliorcetes, and of course the brother of Antigonus Gonatas. Being appointed guardian to Philip, the infant son of Demetrius II., he was called to, or usurped the throne, B.C. 229; but he acted the part of a kind of protector to Philip, who succeeded him. He enlarged the limits of the Macedonian monarchy, and took an important share in the affairs of Greece, for the most part in concert with Aratus and the Achæan league. [See ARATUS, and CLEOMENES.] He died B.C. 221 (Feb. 220, Clinton), regretted by the friends of Macedonia, and leaving a fairer character than belonged to most of the princes of that age.

ANTI'GONUS CARYSTIUS, probably a native of Carystus in Eubœa, is the reputed author of a work, intitled a *Collection of Wonderful Histories* (ἱστοριῶν θαυμάτων συλλογή). Antigonus is generally supposed to have lived in the age of Ptolemy II. of Egypt. This collection, which on the whole is of very little value, was last edited by J. Beckmann, Leipzig, quarto, with a commentary.

ANTIGUA, one of the Caribbee Islands. The town of Saint John, the capital of the island, is in 17° 10' N. lat., and 61° 57' W. long. Antigua was discovered by Columbus in 1493, and was named by him after the church of Santa Maria de la Antigua, in Seville.

The first settlement that was made on Antigua was by a few English families in 1632. Thirty years from that time the island was granted by Charles II. to Lord Willoughby: in 1666, it was invaded by a French force, which laid waste all the settlements. A few years afterwards Antigua was again settled by Colonel Codrington, who was appointed its governor, and whose family still possesses considerable estates on the island.

Antigua is about twenty-one miles long, and is nearly of the same breadth. The land in cultivation amounts to 59,623 acres. Rather more than half of this area is occupied by sugar plantations, the remainder being employed for raising provisions. In 1832, there were exported from the colony equal to 11,010 hogsheads of sugar, 7342 puncheons of molasses, and 1238 puncheons of rum. A considerable quantity of cotton was formerly produced, but its cultivation is now discontinued. Two descriptions of soil are prevalent in the island: one a rich black mould on a substratum of clay; the other a stiff clay on a substratum of marl, which is not so fertile as the former description of soil. It contains a large proportion of level land, and is not in any part mountainous. The shore is in general rocky, and surrounded by dangerous reefs, which make it difficult to approach, but there are several excellent harbours, in one of which—English Harbour, situated on the south side of the island—is a dock-yard belonging to government, with every convenience for careening and repairing vessels: this harbour is capable of receiving the largest ships in the British navy, and here, during the war, the king's ships on the West India station were usually moored during the hurricane months.

The island does not contain a single river, and the few inconsiderable springs it has are so brackish, that the inhabitants are forced to collect rain-water, and preserve it in cisterns for domestic use. It was probably owing to this deficiency that Antigua was not inhabited by the Caribbs, the aborigines of these islands, and that the settlement of it by Europeans proceeded for a long time but very slowly. The island is now divided into six parishes, each of which has a town or village, and eleven districts. It contains six churches, the same number of chapels, and nine other places of worship belonging to Methodists and other dissenters. The Moravian United Brethren have an establishment on the island for communicating religious instruction to the slaves.

The town of Saint John, on the north-west side of the island, is built at the bottom of the bay of the same name, which is defended by a fort, and forms an excellent harbour. The town is on the side of a hill, and its streets are in some parts very steep. This town is considered to be one of the most healthy in the Leeward Islands; it is exposed to the sea-breeze, and from its situation is freed from all impurities by every shower that falls.

Willoughby Bay, on the south-east side, has its entrance much contracted by a reef, but is secure within, and affords good anchorage in four to five fathoms water.

On the north side of the island is the small town of Parham, built on the south side of a spacious harbour, which, however, has not depth of water sufficient for large vessels. A little island, called Prickly Pear, lies off the west point of the entrance to Parham Harbour. Falmouth Harbour is to the westward of English Harbour, already mentioned. The town of Falmouth is built on the western side of this harbour, which is defended by a battery on an islet within, and affords good anchorage in from three to six fathoms of water. Five Islands Harbour, on the western side of the island, is a large harbour so called from five remarkable islets, which lie nearly in a line from east to west about half a mile off the point on its south side.

The executive government of Antigua is vested in a governor, whose jurisdiction extends to the islands of St. Christopher, Nevis, Montserrat, and the Virgin Islands. Its legislature consists of a council nominated by the crown, and a house of assembly composed of twenty-four members, who are chosen by the freeholders of the island. The public revenue of the colony amounts to about 16,000*l.* per annum, and the value of its exports, which are principally made to Great Britain, amounts to about 300,000*l.*, employing between forty and fifty sail of shipping. Antigua has also a considerable trade with the neighbouring British and foreign colonies, in the prosecution of which trade upwards of 300 small vessels annually enter and leave the different ports of the island.

The population of Antigua comprises 35,714 souls, of whom 5875 are whites and free coloured people, and 29,839 are slaves. It contains nineteen schools, in which about 1200 children are educated. In seven of these schools, which are in the towns, about 500 pupils are instructed according to the National System. There are besides several Sunday schools, which are numerous attended; and nine estate schools in different parts of the country, where the children of slaves are taught to read. In the course of the last year (1832) two laws were passed in the colony of great importance to the black and coloured population; one of these is 'an act for relieving free coloured and black persons from all political restraints and disabilities, and for securing to them an equal and unqualified participation in all political rights and privileges; the other is 'an act for declaring the evidence of slaves admissible in criminal courts of the island.'

Antigua is forty-four miles east of Nevis, twenty-five miles south of Barbuda, and about forty miles north of Guadeloupe. (Purdy's *Colombian Navigator*; Alcedo's *Dictionary*; *Government Statistical Tables*.)

ANTILIBANUS. [See LIBANUS.]

ANTILITHICS. [See LITHONTRYPICS.]

ANTILLES, a term applied to portions of the West India islands, but with regard to its exact limitation geographers differ widely. Hoffman confines it solely to the Caribbean group, and says,—'they are called the Antilles of America (quasi ante insulæ Americæ), from lying in front of the larger islands of the Mexican Gulf.' Rochfort and Du Ferre explain the term nearly in the same manner; but D'Anville, qualifying it by the addition of the words

Greater and Lesser, applies the former to Cuba, Hispaniola (or Hayti,) Jamaica, and Porto Rico, and the latter to Aruba, Curaçoa, Buen Ayre, Margarita, and others along the coast of South America, thus entirely excluding the Caribbean group. Some derive the term from the words *Ante Ilas* (Forward Islands); while others assert that, in maps constructed before the existence of a new continent was known, the name Antilla was assigned to a supposed country westward of the Azores, and that when Columbus first saw the Antilles he gave them that name in consequence. By a recurrence to the early Spanish historians, it appears at least that the word Antilla was applied to Cuba and Hispaniola previous to the discovery either of the Caribbean islands or the continent of America; thus Peter Martyr, who wrote his work in Latin only eight months after Columbus's return from his first expedition, says, 'he gives it out that he has discovered the island Ophir, but after carefully considering the world, as laid down by cosmographers, those must be the islands called Antillæ; this island (of which he is speaking) he called Hispaniola.' It is here proposed, however, to adopt the classification of Greater and Lesser, the former comprehending Cuba, Hayti, Jamaica and Porto Rico; and the latter, all the Caribbean group, with those lying along the coast of South America. This definition of the term is now adopted by the best Spanish authorities.

With the exception of Hayti, which has established its independence, the islands are subject to the following European powers:—

GREATER ANTILLES.—*England.* Jamaica.

Spain. Cuba, and Porto Rico.

LESSER ANTILLES.—*England.* Antigua, Barbadoes, Barbuda, Anguilla, Dominica, Grenada, Grenadines, Virgin Islands (part), Montserrat, Nevis, St. Christopher, Saint Lucia, St. Vincent, Tobago, Trinidad.

Spain. Margarita, Testigos, Tortuga, Blanquilla, Orchilla, Rocca, Aves.

France. Guadeloupe, Martinique, Marie Galante, All Saints, Desadea, Saint Martin (north part).

Holland. Buen Ayre, Curaçoa, Aruba, Saint Martin (south part), Saba, Saint Eustatius.

Denmark. { Saint Thomas, } part of the Virgin Islands.
 { Saint John, } group.
 { Saint Croix, }

Sweden. Saint Bartholomew.

Their geographical position is between 10° and 23° 30' N. lat. and between 59° 30' and 85° W. long.

These are again subdivided into windward and leeward, terms which are purely conventional, having necessarily local reference, and differing with different nations according to the position of their respective possessions. In English maps the Caribbean chain has generally been divided into two classes, the windward and leeward, but this distinction seems useless and improper, as, with reference to the trade-wind, the whole group constitutes the Windward islands, and under this appellation they are now commonly all included, while those lying along the coast of Colombia are called Leeward islands. In short, the Antilles is but another name for the West Indies generally, exclusive of the Bahamas; the term West Indies having been bestowed on them near the time of their discovery from the supposition of their belonging to the continent of Asia.

There is great difficulty in treating of the Antilles as a group, as they differ so widely in many respects: the Greater appear to be of primitive formation, with lofty granitic mountains, but most of the Lesser exhibit manifest proofs of their volcanic origin. Craters are still visible in some, though no volcanoes have been in active operation since their discovery. They are all subject to violent shocks of earthquakes, and there is scarcely one in which some memorial of disaster from this cause does not exist. The memorable earthquake which destroyed Lisbon, on the 1st Nov. 1755, was felt in these islands, the shock occurring four minutes later than at Lisbon.

Between August and the latter end of October, the islands, except Trinidad and Tobago, which lie farthest to the south, are subject to the most violent hurricanes; the fury of the wind on these occasions is inconceivable by those who have not witnessed it. Happily, however, these hurricanes are not of very frequent occurrence, and they are never experienced except during the short period of the year already mentioned. Were their visits more frequent, these fertile islands would soon be converted into deserts, since no one

would be willing to employ capital and labour for their cultivation when every moment might deprive him of the fruits of his industry.

The general aspect of this archipelago is mountainous: the summits of the elevated lands are sometimes pointed and naked, and sometimes rounded and wooded. The volcanic islands have isolated conical and pyramidal mountains, whose tops are often above the clouds; their surface is intersected with deep ravines and bristled with rocks; the soil is mostly argillaceous and watered by numerous streams. In islands of such an extent as the Greater Antilles, harbours exist on all sides; the coast of Cuba particularly is deeply indented with safe and landlocked ports. But among the Caribbean, the best and generally the only anchorages may be looked for in bays on the west or lee side; the greatest elevations are nearer the eastern shore, which is bold and precipitous and exposed to the whole force of the Atlantic current, setting through the various passages at the average rate of about a mile an hour; this current is more rapid towards the main, but decreases in velocity among the more northern islands. All the Antilles are more or less surrounded by, or interspersed with, coral formations of reefs or islets called cayos or keys, which render the navigation intricate and dangerous. There are some islands of calcareous formation, probably with a volcanic base; these present undulating plains, and do not attain half the height of the volcanic mountains: they are but scantily watered by small brooks, the soil is dry, with few trees, but the air is more salubrious. In the Antilles, moisture and heat combined produce a surprising luxuriance of vegetation: the soil is in general productive far beyond that of most parts of Europe, but in many islands it has been greatly impoverished by the short-sighted policy of the proprietors. These islands are infested with myriads of insects, mosquitos, sand-flies, &c., which are the cause of constant annoyance to the inhabitants.

The Caribbean islands have the appearance of a continuous chain; but with a line of 100 to 150 fathoms, which is the greatest length commonly used, except for scientific purposes, no bottom is found between the larger islands of the group, nor on either side east or west of them.

The year, as in most tropical climates, may be simply divided into two seasons, the *dry* and the *wet*, yet sufficient variation exists to mark the four seasons of more temperate regions. The spring may be said to commence with April, when a bright and beautiful verdure, with a rapid and luxuriant vegetation, make their appearance; and during the month of May, gentle showers (as compared with the autumnal rains) fall generally every day about noon and break up with thunder-storms. From May till October, the tropical summer reigns in full glory; and before the sea-breeze or trade-wind sets in, the heat is scarcely supportable. This refreshing wind, whose advance is visible over the sea for some time before it reaches the shore, begins between 10 and 11 in the forenoon, and blows with great regularity, increasing in force till about 3 in the afternoon, and then dies away entirely about sunset. The medium height of the thermometer at this season is about 80°. The nights are transcendently beautiful and tempered by a land-wind, which (especially in the mountainous islands) blows gently off the shore from about 10 till daylight. With October commence the autumnal rains, when the water literally pours down in torrents, from 60 to 65 cubic inches being about the medium for seasonable years, but at Barbadoes in 1754 no less than 87.1 cubic inches was ascertained to have fallen. This continues till the middle of December, between which time and April, which is in fact the winter, serene and pleasant weather prevails with a reduced temperature. The climate, more especially of the Greater Antilles, is justly considered unhealthy; the yellow fever rages as an epidemic with great violence, and carries off annually numbers of Europeans, nor do the native negroes themselves altogether escape its fatal effects.

Most of the islands produce sugar, coffee, and cotton; many tobacco and cocoa; and some indigo, lignum vitae, pimento, &c., which, with rum and molasses, constitute their commerce with the mother countries; in return they take articles of luxury and plantation stores. The land is cultivated entirely by the labour of slaves, who form more than four-fifths of the whole population.

The Lesser Antilles have little communication with the other islands owing to the great difficulty of returning; indeed only very fast vessels can work their way back against

the wind and current. The intercourse between themselves is partly carried on in small vessels called droggers.

The islands under the British dominion have their own colonial governments, consisting of an elective legislative assembly, who enact all local laws for the internal regulation of their respective islands, subject, however, to the veto of a governor appointed by the crown. St. Lucia and Trinidad have no legislative assembly, but are administered by resident governors, acting under the orders of the Colonial Secretary in England. Those belonging to foreign powers are governed by the laws of the states to which they belong.

The tides are irregular and uncertain, varying much in the different islands; for instance, at Jamaica the rise is scarcely perceptible, amounting at the maximum to eight inches, while at Trinidad it reaches six feet. The flood sets to the eastward, but on the open shore its effects are counteracted by the current which sets through the whole group to the westward.

Having thus given a slight sketch of the general character and appearance of this archipelago, we refer to other parts of this work for a more particular description of the islands which compose the group. (Edwards's *History of the West Indies*; Purdy's *Colombian Navigator*.)

ANTILOGARITHM, as used in this country, means the *number to the logarithm*. Thus, in Brigg's system, 100 is the antilogarithm of 2, because 2 is the logarithm of 100. We have introduced this term, because the French *Encyclopædia*, followed by Dr. Hutton, have defined the word to mean what is more usually called the *complement* of the logarithm, viz., the remainder produced by subtracting the logarithm from the next higher term in the series, 1, 10, 100, &c. This is not the most commonly received meaning of the word in this country.

It is becoming usual to express the number to a logarithm by writing the logarithm in brackets. There is, however, another notation much more consistent with received symbols. In the same manner as $\sin^{-1}x$ stands for the *angle whose sine is x*, $\log^{-1}x$ should mean the *number whose logarithm is x*. Thus, we might write either

$$\log 100 = 2 \\ \text{or } 100 = \log^{-1}2$$

ANTI-MILO. [See **MELLOS.**]

ANTIMONY, a metal sometimes called *regulus of antimony* to distinguish it from *crude antimony*, the name by which the sulphuret is sometimes called. Antimony was probably known early in the fifteenth century; it occurs, though rarely, native, and is generally procured from the sulphuret, which is the only abundant ore of the metal. When this is heated in contact with iron, the sulphur, on account of its greater affinity for that metal, is separated by it from the antimony, which is consequently reduced to the metallic state. Thus procured, however, it is not pure, but it may be rendered so by mixing it, when reduced to fine powder, with about an equal weight of peroxide of antimony (antimonic acid): the oxygen supplied by this, during fusion, oxidizes and separates the metals mixed with the antimony, which then remains in a pure state.

The properties of antimony are as follows:—its colour is silver white, lustre considerable, and the fracture fine laminated when pure; but the antimony of commerce is broad laminated. When slowly cooled after fusion, it crystallizes in the octahedron or its varieties; it is brittle and easily powdered. Brisson states the specific gravity to be 6.702, Dr. Thomson, 6.436, and Hatchett found the antimony of commerce to be 6.712. When it is exposed to the air, this metal tarnishes, but does not oxidize; if kept under water it suffers no change; at a red heat it melts, and, according to Berzelius, when subjected to a white heat, it volatilizes and distils. Thenard, however, asserts that it is not vaporized even at an intense white heat.

Oxygen and Antimony may be combined in several modes and in different proportions, forming the protoxide or sesquioxide, the deutoxide or antimonic acid, and the peroxide or antimonic acid. If the metal be heated in the open air, it unites with oxygen, and the oxide formed rising in a white vapour, and condensing in brilliant white crystals, was formerly called *argentine flowers of antimony*. When the heat is raised to whiteness, and the metal suddenly stirred, it burns, producing the same oxide; when also steam is passed over ignited antimony in a tube, it is decomposed with explosion, oxide of antimony being formed. According

to Berzelius, the oxide of antimony obtained by the above processes consists of nearly

Three atoms of oxygen $8 \times 3 = 24$ or $1\frac{1}{2}$ atom = 12
Two atoms of antimony $64 \times 2 = 128$ „ 1 „ = 64

Atomic weight 152 Combining weight 76

It is therefore a sesquioxide. The most convenient method of preparing this oxide is to dissolve sulphuret of antimony, reduced to powder, in muriatic acid; sulphuretted hydrogen is evolved, and a colourless solution of muriate or chloride of antimony is obtained; when water is added to this, submuriate of antimony is precipitated in the state of a very white powder, from which the muriatic acid may be separated by heating it in a solution of carbonate of potash. After washing and drying, a dingy white powder remains, which is the protoxide or sesquioxide in a state of purity. This oxide is insoluble in water, but dissolved by dilute nitric acid, and by strong nitric acid it is converted into antimonious acid. Muriatic acid also readily takes it up; the same effect is produced by bitartrate of potash, and the solution on cooling deposits octahedral crystals, which have been long known and employed in medicine under the name of *tartar emetic*, or *tartarized antimony*. It is soluble also in the alkalis, potash, soda, and ammonia; if the submuriate precipitated by water be mixed with potash, a portion of the oxide is dissolved, the greater part, however, diminishes rapidly in volume, and is reduced to a fine greyish crystalline powder, which is a neutral compound of the oxide and potash, and is but slightly soluble in water. It appears, therefore, that this oxide acts as a base with acids, and as an acid with some bases. It operates violently as an emetic, and though now seldom used as such by itself, it is the basis of all emetic antimonial preparations.

Antimonious Acid. This acid, sometimes called *deutoxide of antimony*, may be procured by oxidizing antimony by acting upon it with nitric acid, this yielding oxygen; the mass is to be evaporated to dryness and calcined. Its colour is white, but it is yellowish when hot. According to Berzelius it is composed of nearly

Two atoms of oxygen $8 \times 2 = 16$
One atom of antimony = 64

Atomic weight 80

This acid is neither fusible nor volatile at a red heat; the only change which it suffers by it is that of being less soluble in acids, and combining less readily with bases. When heated with charcoal, it is not easily reduced to the metallic state as the oxide. Its saline compounds are termed *antimonites*, as antimonite of potash, &c.; if it be fused with this alkali the salt formed dissolves in water, from which the acids throw down a white precipitate of antimonious acid, combined with water; in this state it reddens litmus paper, like other acids, but if the water, which amounts to 5.26 per cent., be expelled by heat, it no longer acts as an acid upon vegetable blues. It is insoluble in nitric acid, but slightly dissolved by concentrated sulphuric acid. The antimonites are not an important class of salts.

Antimonic Acid is the peroxide of antimony. This acid is prepared by heating powdered antimony in aqua regia; the solution is to be evaporated to dryness, and the residue treated with nitric acid; it is to be again heated, but not to redness, to expel the nitric acid. The antimonic acid then remains in the form of a pale yellow powder. It is composed of nearly

Five atoms of oxygen $8 \times 5 = 40$ or $2\frac{1}{2}$ atoms = 20
Two atoms of antimony $64 \times 2 = 128$ „ 1 „ = 64

Atomic weight 168 Combining weight 84

Its action on the animal economy is but slight. Antimonic acid is precipitated by water from solution in aqua regia, in the state of white hydrate, and when thus combined with water, it acts like other acids upon vegetable blues. The water amounts to 5.09 per cent., and is expelled by a gentle heat; the acid then becomes yellow and ceases to redden vegetable blues. This acid may be procured by detonating a mixture of one part of powdered antimony with four parts of nitre. water added to the residue dissolves the antimonite of potash formed, and nitric acid poured into the solution combines with the potash and precipitates the acid in the state of hydrate.

Antimonic acid is tasteless and insoluble in water; it does not decompose the alkaline carbonates in the moist way, but when heated with them it combines with the alkali and expels the carbonic acid.

When antimonic acid is subjected to a strong red heat, it loses oxygen and is reduced to antimonious acid, like which, it has but little medicinal power. Neither antimonic acid nor the antimonites are much employed.

Neither nitrogen, hydrogen, nor carbon combine with antimony.

Chlorine and Antimony unite to form two compounds, viz., the proto or sesqui-chloride and the perchloride.

The sesquichloride has long been known under the name of *butter of antimony*; it may be prepared by mixing one part of antimony with two parts of bichloride of mercury (corrosive sublimate) and subjecting the mixture to heat in a retort. By the action of the heat the antimony takes chlorine from the mercury, and the chloride of antimony being volatile distills and has the following properties:—it is a soft and nearly colourless solid; at a moderate heat it liquefies, and it absorbs moisture from the air; when mixed with water it suffers decomposition, and the results are, muriatic acid, the greater part of which remains in solution, and a white powder, which is a compound of protoxide of antimony and a small portion of muriatic acid; it is the submuriate of antimony, formerly employed in medicine under the name of *pulvis Algarotti*. It is dissolved by strong muriatic acid; and by nitric acid the protoxide of antimony is converted into antimonious acid. It has been already mentioned, that when this submuriate is heated with a dilute solution of carbonate of potash, the muriatic acid is separated and protoxide of antimony remains. The same chloride may also be procured by throwing powdered antimony into a jar containing chlorine gas; the antimony burns during combination with the chlorine.

It appears to be composed very nearly of

Three atoms of chlorine $36 \times 3 = 108$ or $1\frac{1}{2}$ atom = 54
Two atoms of antimony $64 \times 2 = 128$ „ 1 „ = 64

Atomic weight . . . 236

Perchloride of Antimony is formed by passing dry chlorine gas over heated antimony. The antimony burns vividly, and a volatile liquid distills which is the perchloride of antimony. It is a colourless or slightly yellow fluid, has a strong disagreeable smell, and emits white fumes. It attracts moisture from the air, and when mixed with water it is decomposed, and converted into muriatic acid and antimonious acid. It is composed of

Five atoms of chlorine $36 \times 5 = 180$ or $2\frac{1}{2}$ atoms = 90
Two atoms of antimony $64 \times 2 = 128$ „ 1 „ = 64

Atomic weight . . . 308

Bromine and Antimony form bromide of antimony; these substances combine with the evolution of light and heat, and the compound, being volatile, is easily procured by distillation. At common temperatures it is solid, colourless, crystallizes in needles, attracts moisture from the air, and is decomposed by water. It melts at about 206° Fahrenheit, and boils at 518°. It is composed of 64.3 of bromine and 35.7 of antimony. Iodine also combines with antimony to form an iodide; it consists of 74.7 iodine, and 25.3 antimony. But neither this nor the bromide is applied to any use.

Sulphur and Antimony combine to form several compounds; the first to be noticed is a native compound, frequently called *crude antimony*, which is the principal ore of the metal. It is found in many parts of the earth; it is of a lead grey colour, possessing considerable splendour, and is met with compact, in acicular crystals, and in rhombic prisms of considerable size and variously modified: when it is heated in close vessels, it melts without decomposition and crystallizes in striated masses. It is decomposed by nitric acid, which, when strong, converts the antimony into antimonious acid, and when dilute into protoxide. Muriatic acid, when concentrated and hot, decomposes it, dissolving the antimony and evolving sulphuretted hydrogen gas of great purity. It appears to be composed of

Three atoms of sulphur $16 \times 3 = 48$ or $1\frac{1}{2}$ atom = 24
Two atoms of antimony $64 \times 2 = 128$ „ 1 „ = 64

Atomic weight . . . 176

It is therefore a sesquisulphuret. It is much employed in preparing metallic antimony, glass of antimony, crocus of antimony, James's powder, and some preparations in the London and other pharmacopœias.

The sesquisulphuret of antimony may be formed artificially by fusing together a mixture of sulphur and antimony; it has the colour and lustre of the native sulphuret. When also a current of sulphuretted hydrogen gas is passed into a solution of antimony, of tartar emetic for example, an orange precipitate is thrown down, which appears to be a compound of sulphuret of antimony and water; and when the water is expelled, it has the usual appearance of sulphuret of antimony. It may be here observed that the formation of this coloured precipitate is highly characteristic of the presence of antimony.

It appears from the experiments of Rose, that a bisulphuret of antimony may be formed by passing sulphuretted hydrogen gas into a muriatic solution of antimonious acid; and also a persulphuret, by the action of sulphuretted hydrogen upon antimonious acid. These, however, are unimportant compounds.

Sesquisulphuret of antimony is soluble in a hot solution of potash or soda; on cooling, an orange-red substance is deposited, called *Kermes mineral*; this was formerly much used in medicine. When an acid is added to the remaining cold solution, a further portion of a similar precipitate is formed: this is sometimes called the *golden sulphuret of antimony*, and in the *London Pharmacopœia*, *sulphuretum antimonii præcipitatum*. These substances appear to consist of sulphuret and protoxide of antimony combined with water.

The only salt of antimony, strictly speaking, of any great importance, is the double tartrate of potash and antimony, usually termed tartar emetic, or tartarized antimony,—the *antimonium tartarizatum* of the *London Pharmacopœia*. Various processes have been proposed for preparing it: the *London College* directs *glass of antimony* (which is the protoxide of the metal, mixed with some sulphuret and silica, prepared by roasting sulphuret of antimony) to be boiled in water, with an equal weight of bitartrate of potash (cream of tartar). The excess of acid in this salt dissolves the protoxide, and a double tartrate of potash and antimony is formed, which crystallizes in octahedrons. Of all the preparations of antimony this is the most valuable. According to Dr. Thomson, it consists of one atom of tartrate of potash = 114, one atom of bitartrate of antimony = 218, and two atoms of water = 18: its atomic weight is consequently 350. The *Pharmacopœias* also contain a preparation in imitation of James's powder, called *puleis antimonialis*; they are both inert mixtures either of antimonious or antimonious acid and phosphate of lime.

Antimony is susceptible of combining with all metals. It makes them very brittle; and this is especially the case with gold, a thousandth part of antimony rendering it unfit for the uses to which it is generally applied.

The principal alloys of antimony are that with lead, employed as *type metal*, and the alloy of antimony and tin, used for plates on which music is engraved.

ANTIMONY (MEDICAL USES OF). Though the introduction of antimony into the number of medicinal agents was very violently opposed, and even decrees by the Parliament of Paris were passed against its use, it is now justly regarded as a most valuable remedy in many diseases. As antimony cannot produce any effect on the human system, unless when so prepared as to be capable of decomposition by the fluids of the body, the tartarized form, being the most soluble, has properly superseded the others. Its action varies according to the dose, the mode of administration, and the state of the system when it is exhibited. In very small doses, it seems to increase the activity of the function of secretion, particularly of the mucous membranes; hence it occasions a flow of thin fluid from these surfaces, which form the inner lining of the lungs, and intestinal canal; and also an increased action of the skin, and flow of perspiration, if the patient be kept warm. In a larger dose it causes vomiting, with all the phenomena of that action; and from being commonly employed for this purpose, it is designated *Emetic Tartar*. Compared with other emetics it may be said to be distinguished by the ease with which it causes vomiting, as well as by the certainty, though, in this latter respect, it is surpassed by sulphate of zinc (white vitriol). It may be given to persons of any age, except to very young children, for

whom ipecacuanha wine is preferable. It ought not to be given in cases of poisoning, for reasons stated under the head ANTIDOTES, and least of all should it be given in cases of narcotic poisons, since in large doses it is itself a poison, unless vomiting take place; and as, by narcotic poisons, the sensibility of the stomach is so lowered or destroyed as not to occasion the rejection of anything received into it, the impropriety of exhibiting tartar emetic in such cases is manifest. From the extremely small quantity of this substance which is sufficient to occasion vomiting, there is one state in which it is to be preferred to every other means of causing vomiting. By whatever channel tartar emetic is introduced into the system, it invariably excites the stomach to perform the act of vomiting, unless the person be in a state of insensibility or coma; a solution of two grains of it, in three ounces of warm distilled water, may, by a skilful operator, be injected into a vein, when the gullet is obstructed by any extraneous body lodged in it. In the same way it may be sometimes tried in tetanus, or lock-jaw, when the teeth are so firmly clenched together, that nothing can be made to pass them.

As tartarized antimony is decomposed by most bitter or astringent vegetables, which contain tannin, (except oak-bark,) and an insoluble, and consequently an inert, tannate of the protoxide of antimony is thereby produced, such vegetables, in the form of infusion, decoction, or tincture, furnish the best antidote in cases of over-dose, or poisoning by this article, should it not, by inducing vomiting, prove its own antidote. Under these circumstances, we should administer decoction or tincture of yellow cinchona bark, or, when these cannot be easily procured, a strong infusion of tea.

Employed in appropriate doses, its action as an emetic is seldom violent, while it certainly acts more powerfully than other emetics in promoting the secretion of the fluids of the stomach, as well as of the bile and pancreatic juice, with those of the lungs, and indeed all the secretions external as well internal. Now, as the suppression of the secretions is one of the most common occurrences in the early stage of fever, and the restoration, and improved character of these, one of the most favourable signs of its abatement, antimony is employed with great advantage in the treatment of fever, and it cannot be used too early. Indeed many a fever is stopped or prevented by the employment of this or some other emetic, as ipecacuanha, upon the first intimation of the disease being felt. It is also suited to the beginning of each paroxysm of intermittent or remittent fevers (see AGUE). It may also be advantageously given about the period of the expected crisis in continued fever. When the disease is of a highly inflammatory type, it should be combined with, or followed by, saline medicines, but when there is great depression of the vital powers, as in typhus, the salines must be soon laid aside, and stimulating medicines cautiously substituted.

Antimony is also used in some eruptive or exanthematous fevers, such as measles and scarlet fever, being less suited for those in which the eruption is of a vesicular or pustular character, and which affect the deeper layers of the skin. (See Craigie's *Pathological Anatomy*.) Antimony is well suited for rheumatic fever and erysipelas, as in these diseases the liver is deranged, and furnishes an unhealthy biliary secretion. It is also useful in what are sometimes termed mucous and bilious fevers, which are attended with very depraved secretions from the intestinal canal, which may be removed and improved by repeated small doses of an antimonial.

It is also in daily use for the cure of catarrhal affections, i.e. colds affecting the mucous membrane of the lungs.

Tartar of antimony, when intended to act as an emetic, is generally given in the dose of a quarter or half a grain dissolved in distilled water, and repeated every ten or twenty minutes till vomiting occur; but when merely intended to cause nausea, or to act gently on the secretions of the intestinal canal, of the lungs or that of the skin, it is given in even smaller doses, and at the interval of two, four, or six hours. Lately, however, a mode of employing it in much larger and more frequent doses has been practised with marked benefit in several diseases of an inflammatory character, particularly in pneumonia, or inflammation of the lungs. According to this plan, from two to three grains dissolved in water, are given, and repeated every two hours or so, for a considerable time, even for two or three days. The early doses cause vomiting and purging, but these effects soon cease to appear, while the pulse is found to

have fallen to fifty beats, or even less, in a minute. When pursued with caution and managed skilfully, it often enables us to overcome the disease; and to dispense with the removal of so much blood from the system, as might otherwise have been necessary. It ought not to be tried, however, if the mucous membrane of the stomach be in a state of irritation or subacute inflammation, a condition which often occurs during pneumonia. This state of the stomach must be removed by general or local means before we venture upon the exhibition of the antimony.

This plan of administering tartar emetic is generally believed to have originated with the Italian physicians Rasori and Tommasini; but whatever merit it possesses is justly due to Dr. Marryat of Bristol, who proposed it in 1790, many years before its employment in Italy.

Tartrate of antimony is applied externally as an ointment and plaster; and in either way it excites an action of the part, leading to the formation of a vesicular eruption, similar to that of vaccinia or cow-pox; and it is consequently used as a means of counter-irritation, often with great advantage. The ointment and plaster may be prepared of different degrees of strength, but care must be taken not to make them too strong, as the antimony may be absorbed from the ulcerated surface, and produce violent vomiting, which in some cases has been so serious as to cause death.

ANTINO'MIANS, from the Greek, signifies *against the law*. It is applied by theologians to those, if any there be, who hold that faith in Jesus Christ dispenses with, and renders unnecessary, so far as a future state is concerned, the observance of morality and the performance of good works. We say, if any there be, because there is reason to suppose that the accounts of earlier antinomians contain much exaggeration, and that there never was any body of men, worthy to be called a sect by numbers and duration, which professed the above opinion.

So far as avowed abandonment of morals, we find various antinomian sects in the first three centuries; but the name was first applied to the followers of John Agricola, a townsman and contemporary of Luther, born at Isleben in Saxony. His opinions had the tendency above mentioned, and were attacked by Luther, who, with the assistance of the elector of Brandenburg, obliged him to publish a retraction. It must, however, be observed, that Bayle points out (in the article *Islebiens*) the exaggerations which have been made of Agricola's opinions and their source, and that Agricola himself was employed with others in drawing up the *Interim*, a provisional confession of faith, promulgated by the emperor Charles V., at Augsburg, in 1548, which Dupin (and catholic writers are, in general, fair judges between one protestant and another) admits to be perfectly orthodox on the article of justification.

This sect has obtained very little notice from continental writers, and its followers appear rather to have been distributed among other persuasions. The assembly of divines in 1643 condemned several writings which appeared to them antinomian; and the parliament in 1648, in what ought to be called the Presbyterian persecution act, among other provisions, enacted that any one convicted, on the oaths of two witnesses, of maintaining that the moral law of the Ten Commandments is no rule for Christians, or that a believer need not repent or pray for pardon of sin, should publicly retract, or, on his refusal, be imprisoned till he found sureties that he would no more maintain the same.

The little importance of this sect renders it unnecessary to dwell further upon its history; but as the name, like others, is bandied about as a term of reproach by many who do not understand its meaning, we cite from an old English account of sects some of the peculiar opinions which were called antinomian by the orthodox, before the revolution of 1688. The source of the whole is the List of Heresies of Pontanus; certainly not a work to trust to in any other respect than as shewing what opinions it pleased some to attribute to others.

Pursebeia, &c., by Alexander Ross, sixth edition, 1683. 'The antinomians are so called from their opposing and rejecting of the law, which they say is of no use at all under the Gospel, neither in regard to direction, nor correction, and therefore ought not to be read or taught in the church. They say that good works do neither further, nor evil works hinder, salvation. That the child of God could no more sin than Christ could, and therefore it is sin in him to ask pardon for sin. That murder, adultery, drunkenness, are sins in the wicked, but not in the children of grace, nor

doth God look upon them as sinners, and, consequently that Abraham's lying and dissembling was no sin in him. That no man should be troubled in his conscience for any sin. That no Christian should be exhorted to perform the duties of Christianity.'

ANTI'NOUS, a native of Bithynia, and favourite of the Emperor Hadrian, the extravagance of whose attachment was shown by the institution of divine honours to Antinous after his death. Respecting the circumstances of his death there are many stories, but it seems generally agreed that he was drowned in the Nile while Hadrian was in Egypt. The town near which he died was rebuilt by the emperor, and called *Antinos* or *Antinopolis*, instead of Besa, its former name. Its remains exist under the name of Ensené. A new star was said to have been discovered in the heavens, which was called the *soul of Antinous*. Oracles were delivered by him, which must be taken as forgeries invented by Hadrian himself, or according to his order. That courtiers should have lent their countenance to this absurd and profane homage, in compliment to their master's weakness and blind partiality, may easily be credited; but that the worship of this new divinity should have outlived the prince who established it, when no longer enforced either by interest or fear, can only be accounted for by the stubborn credulity of a people over whom superstition had gained the ascendancy. It still prevailed in the time of Valentinian; but it was turned to account by the fathers of the Christian church, to whom it furnished an argument against the pagan system of worship, and the means of exposing the absurd principles of their religion. Among the remaining treasures of ancient sculpture, the statues of Antinous, nearly as numerous as those of the Venus, and very similar to each other, rank among the most beautiful. That originally in the collection of Cardinal Alexander Albani, the most perfect perhaps of those executed for the Roman nobles, for the purpose of paying their court to the emperor, is a standing figure in marble. The head looks downwards, with a melancholy expression, which they all bear: the hair in all of them is arranged in the same manner, covering the forehead nearly as low as the eyebrows. The busts of Antinous are also very fine. (See Xiphilinus: Bayle, *Dict. Hist.*, and the authorities there quoted; also Winkelmann. ii. p. 464, &c. French trans.)

ANTI'NOUS (CONSTELLATIONS). [See AQUILA.]

ANTIOCHEI'A (*Ἀντιόχεια*), commonly called Antioch and Antaki, or Antakieh, a town in Syria on the left bank of the Asy, the ancient Orontes, 36° 12' N. lat., 36° 12' E. long., forty-six geographical miles west of Haleb (Aleppo) and twenty-two due south of Scanderoon or Alexandretta on the gulf of the same name.

'Silver, Brit. Mus.]

Antioch belongs to the Pashalick of Haleb. It stands in the valley of the Orontes, which here forms a fertile plain, about ten miles long and five or six broad (Brown). On the west side of the river is part of the mountain-range of Amanus, and on the east, to the south of Antioch and bordering close upon it, is the northern termination of the mountains called Jebel Akra, the antient Casius. The river at Antioch is from 100 to 150 feet wide, and is crossed by a substantial bridge. The Orontes in antient times was navigated up to the city, a distance of about twenty geographical miles from its mouth, and might again be made navigable for sailing boats if cleared out below. A large part of the immense walls of antient Antioch still remain, but authorities vary as to the circuit enclosed by them. Mr. Buckingham gives them a circuit of nearly four miles; but this is much less than the amount assigned by antient authorities. They run along the river on the N.W., ascend the steep hill on the S.W., on the S.E. run along its summit, and on the N.E. run down the hill to the river. The walls are from thirty to fifty feet high, fifteen feet thick, and flanked by numerous square towers. It seems not unlikely, from the quantity of Roman tiles found in the towers, and the mode of their disposition,

that the existing walls of Antioch are chiefly Roman work: possibly there are but few parts of the original walls erected under the Seleucidæ. It appears indeed most probable that the present walls are those which were erected by Justinian, after the town had been ruined by the Persians. Mr. Buckingham says that one portion of the wall and towers in the S.W. quarter is perfect.

Antioch, though fallen from its antient importance, is still one of the large towns of Syria: the population is stated at about 10,000, but it does not appear to be well ascertained. It has no good public buildings. The houses are chiefly built of stone, pent-roofed, and covered with red tiles. The streets are narrow, with a raised pavement on each side for foot passengers. The bazars are numerous, and contain a good supply of such articles as are in demand in the country about Antioch. The manufactures of the place are coarse pottery, cotton cloth, silk twist, leather, and saddlery. The language of the Mohammedans at Antioch is generally Turkish; there are a few Christian families there, and some Jews. The air of Antioch is reputed to be more salubrious than that of Haleb. The view of the plain of Antioch from the towers above is described as highly interesting: 'The northern portion within the antient walls is now filled with one extensive wood of gardens, chiefly olive, mulberry and fig trees; and along the winding banks of the river, tall and slender poplars are seen.' (Buckingham.) The chief street seems to have run from S.W. to N.E.; following its direction towards the *Bab Boulous*, or 'gate of St. Paul,' which leads to Aleppo, a part of the antient pavement is observed, and on the right of the road within the enclosure, are numerous caves or excavations in the hill, which appear to have been the antient Necropolis or cemetery. The remains of an aqueduct exist to the south of the city.

Antiocheia was founded by Seleucus Nicator, and received its name from his father Antiochus. Antiochia, which Antigonus had previously built near the site of the future Antioch, sunk into insignificance and disappeared before the city of Seleucus. Antioch became the residence of the Syrian monarchs, and one of the largest cities of the world. It probably grew still larger under Roman dominion, when it was the residence of the governor of Syria, the seat of pleasure, and the centre of an extensive commerce. Strabo (p. 750) describes Antioch in his time as consisting of four distinct quarters, each having a wall of its own, and the whole surrounded by a common wall. These quarters marked the successive additions that the city received from the time of Seleucus the founder to Antiochus Epiphanes. The geographer says it was little inferior in extent and wealth to Seleucia on the Tigris and Alexandria in Egypt. Several of the Roman emperors were fond of spending some time here, in a city where the games of the circus and the amusements of the theatre were so much cherished by the prevailing taste of the inhabitants. Under Libanius, a native of the place, it became in the fourth century a celebrated school of rhetoric. But before this period Antioch had also become the chief station of the Christian religion, which had been firmly established here by Barnabas and Paul; and here we are told (Acts xi. 26) that the name of Christians was first given to the disciples.

Antioch continued to be a city of great importance, notwithstanding the frequent and terrible visitations of earthquakes, till Chosroes, the Persian, took it and nearly levelled it with the ground. It was rebuilt by Justinian and again became a considerable place, and continued so till the time of the Crusades, to which epoch some assign the remains of a wall or fort on the hill to the south of the city. Antioch, after it was taken by the Crusaders under Godefroy and Boemond, (A.D. 1098,) became a Christian principality under the European conquerors of Syria. The sultan Bibars, in 1269, took it from the Christians and destroyed its churches. It afterwards passed under Turkish dominion, but has never recovered its commerce and importance, which were transferred to Aleppo. Mr. Buckingham says that the Christians of Antioch have not at present a single church, and that they assemble for prayer in one of the excavations mentioned above. Antioch was taken possession of by Ibrahim Pacha Aug. 1, 1832, but was subsequently restored to the Porte.

The neighbourhood of Antioch is peculiarly rich in medals and engraved stones: great numbers have been collected at different times after the earth has been laid bare by heavy rains in winter. The most interesting are those of the Seleucidæ, and next to them, those of the period of

Julius Cæsar and Augustus: one, of the date of Augustus, is given at the head of this article. Phœnician coins are also found in great quantities.

The last great earthquake at Haleb, in 1822, extended also to Antioch and did some damage. (See Strabo; Man-nert's *Syrien*; Brown's *Travels*; Buckingham's *Travels among the Arab Tribes*; *Journal of Education*, No. II., p. 249; *Itinéraire*, &c. Paris, 1816, without the author's name.)

To the north-east of Antioch is a small lake, called Antakieh or Bahr Agoulé, which communicates with the ORONTES.

ANTIOCHEIA of Pisidia, a town of Asia Minor, where Paul, accompanied by Barnabas, preached the Gospel (Acts xiii.) It seems, that at this time Antioch had some Jews among its population. The position of this town is not accurately known, unless it has been very lately discovered, as some journals inform us. (See Strabo, p. 577.)

ANTIOCHUS, a name best known from its being borne by many Syrian monarchs of the Seleucidan dynasty; but otherwise not uncommon in antient history. We shall devote this article to giving a brief sketch of the history of the Syrian empire under these princes.

I. ANTI'CHUS, surnamed Soter, or Preserver, was the son of Seleucus Nicator, who after the death of Alexander raised Syria into an independent kingdom (see ANTI-GONUS). There is a romantic story told, how he fell desperately sick for love of Stratonice, his father's young wife, the daughter of Demetrius Poliorcetes; and how Seleucus, on learning the cause of his son's disease, resigned her to him, and caused them to be crowned king and queen of Upper Asia.

[Silver, Brit. Mus.]

Upon the murder of Seleucus, while engaged in his expedition to subdue Macedonia, B.C. 280, Antiochus succeeded to the throne and reigned nineteen years, during which few events of much importance occurred. He prosecuted his father's claim to the kingdom of Macedonia against Antigonus Gonatas, son of Demetrius, and his own brother-in-law; but the dispute was accommodated by a marriage between Antigonus and Phila, daughter of Seleucus and Stratonice, in consideration of which the Macedonian prince was allowed to retain the peaceable possession of his throne. Demetrius, the son of Antigonus, also married Stratonice, the daughter of Antiochus. The reign of Antiochus is distinguished by his wars against the Gauls, who had crossed into Asia and obtained a settlement in the province named after them Galatia. Issuing thence they harassed the neighbouring provinces with predatory excursions, until Antiochus defeated them, and obtained the appellation of Soter. He was subsequently engaged in an unsuccessful war with Eumenes, king of Pergamus. Returning to Antioch he found, or took, occasion to put to death one of his sons charged with having excited disturbances in his absence: the other, named also Antiochus, he proclaimed king of Syria. He died soon after, B.C. 261. (Appian, *Syriaca*; Justin, book xxvii.; *Anc. Univ. Hist.* vol. viii.)

II. ANTI'CHUS, surnamed Theos, or God, son of the former, succeeded to the throne upon his father's death. His reign is chiefly memorable for the revolt of the Parthians, B.C. 250, under Arsaces, who succeeded ultimately in expelling the Macedonians, and thus became the founder of the formidable Parthian empire. The remote province of Bactria, and others lying eastward of the Tigris, followed this example: and Antiochus, apprehensive of the final loss of those regions, concluded a treaty of peace with Ptolemy Philadelphus, B.C. 252, by which he agreed to repudiate his wife Laodice, and to marry Berenice, daughter of the king of Egypt, settling the crown upon his children by the latter. These conditions were fulfilled: but on the death of Ptolemy, two years afterwards, Antiochus restored Laodice

to her conjugal rights, and in return was poisoned by her, B.C. 247, with the view of securing the succession to her eldest son, Seleucus Callinicus. He left another son by her, Antiochus, surnamed Hierax, the Hawk; who for several years waged war with his brother Seleucus for the possession of Asia Minor, but being finally overthrown, was forced to fly into Egypt, where he died. (See Schlosser's *Remarks on the Reign of Antiochus II.*, *Universalhistorische Uebersicht*, &c.)

III. ANTI'CHUS, surnamed the Great, was the son of Seleucus Callinicus, and succeeded his brother Seleucus Ceraunus, B.C. 223, who was poisoned by two of his chief officers, while engaged in war with Attalus, king of Pergamus. Antiochus owed his safety and his throne to the honesty of his cousin-german, Achæus; who, though pressed by the army to assume the crown, retained it in obedience to the legitimate heir, and by his good generalship kept Attalus in check. The first care of the young king, or his advisers, was to appoint governors to preside over the several districts of the Syrian empire, which during preceding reigns had lost much of its original greatness. The kingdom of Pergamus had especially profited by the weakness of the Seleucidan dynasty: but under the able management of Achæus, those provinces which had been wrested from the Syrians were recovered, and Attalus was again confined within the limits of his proper kingdom. Antiochus was less fortunate in the choice of Molo and Alexander, two brothers, who were appointed governors of Media and Persia. Trusting to the weakness of a youthful reign, they endeavoured to raise their provinces into independent kingdoms, B.C. 221: and it was not until they had defeated two armies sent against them under subordinate officers, that they were reduced by Antiochus in person, in the second campaign.

Returning into Syria, he found abundant matter to engage his attention. Achæus, who had formerly so signalized his fidelity, now found that his distinguished successes had excited jealousy, and that plots were laid against his life by those who were in the king's confidence. Sacrificing his sense of duty to his personal safety, he proclaimed himself king of those provinces in Asia Minor, which he had recovered, and which had been entrusted to his charge. Thus shorn on the west, the Syrian empire was equally mutilated on the south, where Ptolemy Philopator still held Cœlesyria and Palestine, which had been conquered by his predecessor, P. Euergetes. By the advice of his council, the young monarch turned his arms first against Egypt. He marched into Cœlesyria, and assisted by the defection of Theodotus, the governor of that province, gained possession of the greater part of it, including the capital, Damascus. The campaign was terminated by a truce for four months, to which the contending parties were induced to agree; Antiochus, by the necessity of returning northwards to oppose Achæus, who, not satisfied with his possessions in Asia Minor, aimed at extending them to the eastward of Mount Taurus; and Ptolemy, by the reverses which he had suffered, and the necessity of gaining time to prepare for fresh exertions. Negotiations for a treaty of peace were set on foot: but each party claiming Cœlesyria and Palestine, in virtue of the partition of Alexander's conquests made after the battle of Ipsus, (see *SELEUCUS*) the truce expired before anything was agreed to. War was resumed, B.C. 218. At first, Antiochus carried all before him: he penetrated into Phœnicia, forcing the passes of Mount Libanus; gained possession of Galilee, and subdued the inheritance of the tribes beyond Jordan. But these advantages he lost in the following year in a great battle fought at Raphia, near Gaza, in which he was defeated with great slaughter, and obliged to retreat to Antioch with the wreck of his army. Cœlesyria and Palestine returned to their allegiance to Ptolemy: and the Syrian king, pressed at the same time by Achæus, was compelled to sue for peace with Egypt, which he obtained on condition of resigning his claim to the contested provinces. Being now at leisure, Antiochus turned his whole attention to the destruction of Achæus, whom he overpowered and put to death: by this act the provinces of Asia Minor were again annexed to the Syrian empire, (B.C. 213.)

Having secured his western at the expense of his southern dominions, Antiochus turned his attention towards the east, where the growing power of Parthia threatened serious danger. Arsaces, the son of him who established the Parthian empire, had overrun Media while Antiochus was engaged in the wars against Ptolemy and Achæus. He was

unable to withstand the attack of Antiochus in person, and was soon driven out of his new conquest. The Syrian monarch in his turn invaded Parthia, and after several campaigns, a treaty was concluded, by which Arsaces was left in quiet possession of Hyrcania, on condition of his assisting Antiochus to recover the rest of the revolted provinces. After an unsuccessful attempt to recover Bactria from Euthydemus, with whom he at last concluded a treaty, he crossed the mountains of Paropamisus (also called Caucasus) into India, formed a treaty of alliance with the king of that portion of the country, and directing his march homeward through the provinces of Arachosia, Drangiana and Carmania, intermediate between the Indus and Persia, re-established the supremacy of Syria in those distant regions. He returned through Persia to Antioch, having been employed for seven years in these eastern campaigns. This was the most flourishing period of the Syrian empire since the revolt of Parthia in the reign of Antiochus Theos; and it was at this time that Antiochus had earned by his successes the most specious claim to the title of Great.

Soon after or about the time of the return of Antiochus, Ptolemy Epiphanes, a child of five years old, succeeded to the throne of Egypt, (B.C. 205,) on the death of his father, Ptolemy Philopator. Antiochus and Philip king of Macedonia united in a design to expel him, and share the Egyptian dominions between themselves. The unfortunate provinces of Palestine and Cœlesyria were the bone of contention, the favourite battle-field on which their more powerful neighbours fought out their differences. Antiochus regained possession of them in the course of two campaigns. On his being called away to Asia Minor, Judæa was overrun by Scopas, the Egyptian general; but it was soon reconquered by Antiochus, who, upon entering Jerusalem, (B.C. 198,) was received by the Jewish people with great joy, and with every demonstration of respect; in return, he granted many privileges to them, especially ordaining that no foreigner should be permitted to demand access into the interior of the temple. But, finding the power of Egypt still unbroken, and his own resources incompetent to wage war on two sides of his empire at once, and being anxious to recover all that had belonged to the first Seleucus in Asia Minor, Antiochus now proposed a treaty of marriage between his daughter and the young king of Egypt, to be consummated when both came of age, by which Cœlesyria and Palestine were to be given with the princess as a dowry. Having thus purchased the neutrality of his most powerful enemy, he proceeded with a powerful fleet round Asia Minor, reducing, in his way, many of the maritime Greek cities. He crossed the Hellespont, and took possession of the Thracian Chersonese, (B.C. 196,) which he claimed for his inheritance, as having been conquered by Seleucus Nicator from Lysimachus; and here he came in contact, for the first time, with the power before which his own was compelled to retire. The Romans had already reduced Macedonia to the condition of a subject kingdom, thus indicating the extent of their ambition, and the probable consequence of their success in the second Punic war, when Antiochus crossed into Europe, and wrested the Chersonese from the impaired power of Philip. Jealous of this new interferer in the affairs of Europe, the Romans sent ambassadors to require restitution, not only of all that Antiochus had taken from Philip, but of all that he had taken from Ptolemy, whose guardians, soon after his accession to the throne, had placed him under the wardship of the Romans, as a protection against the ambition of his Syrian neighbour. Antiochus replied to these requisitions in terms as haughty as those in which they were made; and it was evident that the quarrel would soon end in an appeal to arms. (See Polybius, xviii. 33.)

In the following year, (A.C. 195,) Hannibal, driven from Carthage, came to Ephesus to seek the protection of the king of Syria; and his representations, joined to the known value of his services, fixed the wavering determination of Antiochus, and induced him to match his strength against the redoubted power of Rome. A period of negotiation elapsed, in which neither party would abate from their pretensions, and neither probably was sincerely desirous of peace. It was both the misfortune and the fault of Antiochus, that he suffered his confidence to be alienated from Hannibal, and allowed him no share in the direction of affairs. In the winter of 192 B.C., Antiochus was invited by the Ætolians to pass into Greece. He crossed over with an army, posted himself in the town of Demetrias, and was

chosen by the *Atolians* as their commander-in-chief. Antiochus appears to have managed affairs badly. He might have made the king of Macedonia his friend instead of his enemy; and after his capture of Eubœa, instead of pushing on his conquests, he spent his time at Chalcis, and in negotiating with the petty states around him. The Roman consul, *Acilius Glabrio*, with Cato for his legate, now advanced against the Syrian king, who made a stand at Thermopylæ, but was utterly routed and compelled to retire to Asia, (B.C. 191.) The next year *L. Cornelius Scipio* was elected consul, and appointed to conduct the Syrian war, and his brother, the celebrated *Africanus*, served under him in the quality of lieutenant. Under their able guidance the war was soon terminated; and its end was hastened by the unskillful conduct of Antiochus. Disheartened by his reverses, and especially by a second defeat at sea, he withdrew his forces from *Lysimachia*, in Thrace, and from the strong cities on the Hellespont, which would at least have retarded the progress of the Romans for some time; and thus he gave them free access into Asia. Yet they had no sooner crossed the Hellespont, than, struck with terror, he sent ambassadors to endeavour to negotiate a peace. The terms he offered, though tolerably humiliating, were not such as satisfied the ambition of the Romans, who required that he should defray all the expenses to which they had been put during the war, set at liberty all the Greek cities, and evacuate the whole of Asia Minor west of Mount Taurus. These conditions Antiochus, thinking that no harder could be imposed on a conquered enemy, refused to accept, and collecting his whole force, he met the consul *Scipio*, (B.C. 190,) in a pitched-battle near *Magnesia* of *Sipylus*, in which he was defeated with immense slaughter. This was decisive: he retired hastily to Syria, and again sent to negotiate for peace, which he obtained on terms not materially harder than those before offered, yet such as must have been very galling to the haughty monarch, and hitherto successful conqueror. He was to resign the provinces west of Mount Taurus; to pay 18,000 Euboic talents for the expenses of the war; to deliver up to the Romans his elephants and ships of war; and, a yet more disgraceful stipulation, to place in their hands *Hannibal*, and other foreigners who had taken refuge at his court from the hatred of that grasping and revengeful people. *Hannibal*, with another, preserved his safety by timely flight; the rest were delivered up, together with hostages for the observance of the treaty, of whom Antiochus *Epiphanes*, the king's younger son, was one.

Antiochus did not long survive this humiliating treaty, which was, in some degree, the cause of his death. In collecting means to pay the heavy burden imposed upon him, he was led to plunder a wealthy temple in the province of *Elymais*. Indignant at the sacrilege, the people of the place rose in arms, and massacred him and his attendants, (B.C. 187,) in the thirty-seventh year of his reign, and fifty-second of his age. He merited the title of Great, only as being the most eminent of a series of princes of the same name, none of whom were distinguished either for talent or goodness. He did more, however, to restore the greatness of the Syrian kingdom under the first *Seleucus*, than any other of his dynasty; but he was unfortunate in meeting the first shock of that iron power before which all the great monarchies of the known world were destined to fall. (Polybius, lib. 5. &c.; Appian, *Syriaca*; Liv. lib. 36, 37; *Raleigh, Hist. of World*; *Anc. Univ. Hist.*, vol. viii.)

IV. ANTIOCHUS, surnamed *Epiphanes*, or *Illustrious*, the second son of Antiochus the Great, succeeded his elder brother *Seleucus Philopator* (B.C. 175 or 176). Antiochus was, at the time of his brother's death, on his way from Rome, where he had been detained as a hostage for the observance of the treaty concluded with his father after the battle of *Magnesia*.

The first events of his reign which require notice, are his hostilities with Egypt, which then reclaimed the provinces of Palestine and *Cœlesyria*, wrested from her by Antiochus the Great. In the first campaign, (B.C. 171,) he routed the Egyptians between Mount *Casius* and *Pelusium*, and took advantage of his success to fortify the frontiers of Palestine against farther aggression. Pursuing his success, in the next year he overran all Egypt, except the strong city of Alexandria, and gained possession of the person of *Ptolemy Philometor*, the young king. In the same year he sacked Jerusalem, and profaned and plundered the temple, as related in *Maccabees* i. c. 1, and ii. c. 5; after which he appointed *Philip* the Phrygian governor of Judæa. After the capture of the reigning prince, the Alexandrians raised *Ptolemy Euergetes*, commonly called *Physcon*, his brother, to the throne. This induced Antiochus to undertake a third expedition to Egypt (B.C. 169); in which, under pretence of restoring the kingdom to *Ptolemy Philometor*, he renewed the war, defeated the Egyptians, and laid siege to Alexandria. Being unable to reduce that city, he left *Philometor* as the nominal king of the country, retaining in his own hands only the strong city of *Pelusium*, the key to Egypt on the side of Syria. He hoped that the quarrels of the rival brothers would exhaust the strength, and facilitate the entire reduction of that country; but here he was disappointed; for seeing through his ambitious designs, they agreed to hold the kingdom in common, and Egypt was restored for a time to its former tranquillity. Hereupon Antiochus undertook a fourth expedition (B.C. 168), entered and subdued Egypt, and was on the point of laying siege to Alexandria, when he was met by ambassadors from Rome, who peremptorily required him to depart from Egypt, and the imperious mandate was obeyed. Returning through Palestine in the same year, he vented his spleen by ordering that great persecution of the Jews related in the second book of *Maccabees*, in which the temple was polluted, and its service broken off, until, after the lapse of more than three years, it was restored by *Judas Maccabæus*. Of the *Maccabæan* wars we shall give an account under the article *MACCABEES*: the cruelties perpetrated on the insurgent Jews in the course of them, by the agents, and under the command of Antiochus, have rendered his name deservedly hateful. The steady and successful resistance of that high spirited people drained Syria of army after army: and the difficulties of the king were increased by revolts in Armenia and Persia. Dividing his disposable force into two parts, he sent one under the command of *Lysias* into Judæa; and led the other himself into the revolted provinces, which he soon brought back to their allegiance. While thus employed, he received tidings of the total defeat of his armies in Judæa. Transported with passion, he hastened towards Antioch, devoting the Jewish people to destruction, when, in the midst of his imprecations, he was seized with violent internal pains. Still he continued to pursue his journey with precipitation, until he fell from his chariot, and was so much injured as to be obliged to halt at a town called *Tabæ*; the situation of which is not certainly known. There he died, B.C. 165, in dreadful agony both of body and mind. He was a prince of dissolute and undignified character, as well as stained with the darker vice of cruelty. Given up to drunkenness, to low debauchery, and to gross buffoonery, he received from his subjects the nickname of *Epimanes*, or the Madman, in parody of his assumed title of *Epiphanes*, or *Illustrious*. (Livy, xlii., &c.; Polybius.)

V. ANTIOCHUS, surnamed *Eupator*, or well fathered, son of A. *Epiphanes*, a child nine years old, succeeded to the throne, under the guardianship of *Lysias*, well known in the Jewish wars. After a nominal reign of nearly two years he was dethroned, and put to death by his cousin-german, *Demetrius Soter*, son of *Seleucus Philopator*, who succeeded to the crown, B.C. 162.

VI. ANTIOCHUS, was the son of *Alexander Balas*, who, being deposed by *Demetrius Nicator*, son of *Demetrius Soter*, and perishing in Arabia, left a son, A. *Theos*; who was raised up by *Diodotus*, surnamed *Tryphon*, as a stalking horse, by the help of which he might displace *Nicator*, and make his own way to empire. The young pretender was at this time but seven years old; but he was readily raised to the throne, for the excesses of the reigning prince had alienated his subjects. After a nominal reign of two years he was put to death by *Tryphon*, who assumed the crown. (B.C. 144-2.)

VII. ANTIOCHUS, surnamed *Sidetes*, or the Hunter,

(so named from a Syriac word, signifying to hunt, according to some authorities, but more probably from the town of Side,) was a younger son of Demetrius Soter, and brother of Demetrius Nicator. The latter, when expelled by A. VI. and Tryphon, experienced various fortunes, and fell at last into the hands of the Parthians. A. Sidetes then married his brother's wife, Cleopatra, laid claim to Syria, and expelled Tryphon, (B.C. 138,) who had held it since the murder of A. VI. His reign was prosperous and tranquil, compared with the weak and turbulent governments of his immediate predecessors. He reduced many cities, which had taken advantage of the civil wars to assume independence, and among them Jerusalem (B.C. 134): and he engaged in a war with Parthia, which had profited by the distractions of Syria to usurp much of her eastern dominions. He defeated Phraates, king of Parthia, in three battles, compelled him to retire within the limits of Parthia itself, and recovered all which had been wrested from Syria, except that province; but his life and reign were brought to an untimely close in a sudden onset made by the enemy upon his winter quarters. He perished, B.C. 129 or 128, leaving a fairer character for justice, generosity, and bravery, than belongs to most of the princes of this most profligate age.

VIII. ANTIOCHUS, surnamed Grypus, or Hook-nosed, from γρύψ, a vulture. After the death of A. Sidetes, Syria was again distracted by civil wars. Demetrius Nicator escaped from Parthia, and resumed the crown; but he was soon dethroned by Alexander Zebinas. Cleopatra, the wife successively of Balas, D. Nicator, and A. Sidetes, retained possession, however, of a portion of Syria; and Seleucus, her son by D. Nicator, regained some districts contiguous to those held by his mother, and proclaimed himself King of Syria. This raised her jealousy, and she murdered him with her own hand. Still thinking it necessary to have some one of royal blood to give countenance to the sovereign power which she was bent on acquiring for herself, she recalled from Athens, her son Antiochus Grypus, (named also Philometor, and, on his medals, Epiphanes,) B.C. 125. Supported by Egypt, Grypus soon expelled Alexander Zebinas. Cleopatra then became jealous of him also; and perished, being compelled to drink a poisoned draught, which she herself had offered to her son. Grypus then reigned in peace for eight years; at the end of which a fresh competitor for the throne started up in the person of his half-brother.

IX. ANTIOCHUS, surnamed Cyzicenus, from being educated at Cyzicus, the son of Cleopatra by A. Sidetes. After a sharp contest the brothers agreed to divide the empire, B.C. 113 or 112: A. Cyzicenus occupied Cœlesyria and Palestine; A. Grypus, the rest of the empire. Both led a dissolute and careless life, and several great cities, as Tyre, Sidon, &c., profited by their supineness to assume a short-lived independence. Grypus was assassinated, B.C. 96. A. Cyzicenus was defeated and slain by Seleucus, the son and successor of A. Grypus, B.C. 95. Seleucus perished, after a short reign, if a period of contest may be called such, of seven months.

X. ANTIOCHUS, surnamed Eusebes the Pious, son of A. Cyzicenus, proclaimed himself King of Syria upon his father's death. For a time he disputed the throne with his cousins, Philip and Demetrius Eukæros, sons of A. Grypus; but (B.C. 88) he was compelled to fly into Parthia. He returned (B.C. 86), Eukæros being dead or banished: and while he was engaged in war with Philip, another Antiochus, surnamed Dionysius, full brother to Philip, seized upon Cœlesyria. The latter was soon slain in a war against the Arabians. After a brief period, the Syrians, wearied by the desolating feuds of the Seleucidan princes, invited Tigranes, king of Armenia, to take possession of the country. Eusebes then fled into Cilicia, (B.C. 83,) and passed the remainder of his life in obscurity. The events of this reign are very confused.

XI. ANTIOCHUS, surnamed Asiaticus, was the son of A. Eusebes. Tigranes being obliged to withdraw his troops from Syria to make head against the Romans, A. Asiaticus gained possession of part of the kingdom, B.C. 69. He retained it for four years, at the end of which Syria was reduced by Pompey to the condition of a Roman province, B.C. 65. In Antiochus Asiaticus, the Seleucidan dynasty ended, having ruled Syria for 247 years, reckoning from the time when Seleucus Nicator began his reign in B.C. 312. (For the chronology of the Syrian kings the reader should consult Clinton's *Fasti Hellenici*.)

ANTIOCHUS OF COMMAGE'NE. [See COMMAGE'NE.]

ANTI'PAROS, called also by the antients Olearos, one of the group of the Cyclades, is situated between Siphnos and Paros, and separated from the latter by a dangerous channel one mile and a half wide. It is seven miles long, north and south, and three miles broad, and contains one small village, with about 300 inhabitants; its productions are trifling, consisting only of a small quantity of poor wine, and a little cotton and barley. The island is a mass of white marble, and is only celebrated for its grotto: the entrance to it, which is on the side of a rock, is by a low arch formed of rough craggy rocks, about thirty paces wide, and divided into two by several natural pillars. This passage continues about twenty yards, at the end of which is a precipice that must be descended by the aid of ropes, fastened to the masses of stalactites; after advancing a little farther under a ridge of rugged rocks, there is another descent, but not so precipitous as the last. Another passage about nine feet high and seven wide, whose walls and arched roof, composed of glittering white and red marble, are as smooth as if wrought by art, leads to a third precipice, the sides of which appear like a sheet of amethysts. Then follows a sloping passage of about 500 yards, on each side of which the petrifications assume the appearance of a ragged curtain partially drawn, and occasionally of snakes coiled up in folds; this conducts to the fourth and last descent. At the bottom of this is the grotto 120 yards long, 113 wide, and 60 feet high; it is an immense arch of white marble, from the roof of which depend large stalactites ten feet long, and as thick as a man's waist, with a thousand festoons and leaves of the same substance; the floor is rough and uneven, with various coloured crystals and stalagmites rising up; and in the midst is one, twenty feet in diameter, and twenty-four feet high. It was this pyramid of stalagmite that served as an altar when M. de Nointel visited the grotto, and celebrated mass on it. When lighted up, the whole presents a most brilliant and magnificent scene, but the smoke from the torches of the numerous visitors has somewhat dimmed its effulgence. In some places the stalactites have partitioned off portions of the cavern into cells. The difficulty of reaching the grotto has latterly been much diminished by the provision of rope-ladders, torches, &c., for which the guides make a small demand on the purse of the traveller. It is not certain that the extremity of the grotto has ever been explored. The highest point of the island is in 37° N. lat., and 25° E. long. (See also Tournefort's *Voyage au Levant: Encyclopédie Method. Géog. Physique*.)

ANTI'PATER, a Macedonian of high birth and high reputation, the chosen and trusted officer of Philip and of Alexander the Great. He was the pupil and friend of Aristotle; he was learned himself, and the patron of learned men. When Alexander left Europe for Asia, he entrusted the government of Macedonia and the regulation of Greece to Antipater. During the year B.C. 331, an attempt was made by Lacedæmon, Achaia, Eleia, and the greater part of Arcadia, to deliver Peloponnesus from the supremacy of Macedonia. Antipater, marching into Peloponnesus to quell the disturbance, was met by Agis, king of Lacedæmon: and a battle ensued in which the latter was slain, and his army defeated and broken. The victor summoned a congress to meet at Corinth, at which a fine of 120 talents was imposed upon the Eleians and Achæians; the Lacedæmonians were obliged to submit at discretion, referring their punishment to the arbitration of Alexander. It does not appear that any severe measures were taken against them.

Well acquainted with the dangerous temper of his mother Olympias, Alexander had abstained from allowing her any share in the administration of Macedonia during his own absence. She did not bear this exclusion patiently, and succeeded in raising jealousies between her son and Antipater, insomuch that Alexander determined to remove his viceroy to a less independent situation. Shortly before his death he sent home Craterus, a distinguished officer, in command of a large body of Macedonian veterans who had earned their discharge; and commissioned him to assume the government of Macedonia, while Antipater was ordered to conduct fresh levies to Babylon. A report was current, but it is not corroborated by the best authorities, that Antipater, fearful of a like fate to that which had overtaken Parmenion, and others of his master's followers, administered poison to Alexander, by means of his sons Cassander and Iolas, who held the office of cup-bearers.

We do not give credit to this story: but it is certain that Alexander did die at a critical time for the fortunes of Antipater, before Craterus had reached Greece. The late king's brother Arrhidaeus, a bastard son of Philip, was raised to the throne by the Macedonian generals, and the army in Asia; and Perdiccas was appointed viceroy over the king, who was a young man of weak intellect, with the same sort of power as the Maires du Palais exercised in old times in France towards the end of the Merovingian dynasty.

In the distribution of provinces among the chief officers of Alexander, to be held nominally in subordination to the Macedonian crown, though in fact, and speedily in name, converted into separate and independent kingdoms, Antipater was confirmed in the possession of Macedonia, and the adjacent countries. He was soon provided with employment. The Athenians, impatient of the superiority of a nation whom they hardly acknowledged to be of pure Hellenic blood, had already made some preparation for war with Macedonia before the death of Alexander was fully known. A vote was passed, that the state would take charge of the common freedom of Greece, and liberate the cities held in check by Macedonian garrisons; a powerful armament was put in preparation, both by land and sea, and ambassadors were sent to invite all the people of Greece to join in the undertaking. Athens was soon at the head of a powerful confederacy, comprising the Ætolians, Thesalians, and almost all the Greeks north of the Isthmus, except the Bœotians; and of Peloponnesus, the Argeians, Eleians, Messenians, and Sicyonians. Leosthenes, the Athenian general, posted the allied army at Thermopylæ, the celebrated pass commanding the entrance into Greece from the north. Antipater, drained of troops by Alexander's frequent demand of reinforcements, was unable to collect more than 13,000 foot and 600 horse, with which he advanced against Leosthenes. A battle ensued, in which the Macedonians were defeated, somewhere between Pylæ and the town of Lamia in Thessaly, to which Antipater retreated, meaning to abide a siege until assistance, for which he had already sent, should arrive from Asia.

Leonnatus, one of Alexander's generals who had obtained the satrapy of Mysia, otherwise called Hellespontine Phrygia, was the first who came to help Antipater. The Hellenes (as Diodorus distinguishes them) broke up the siege and marched to meet Leonnatus; a battle ensued, in which the Macedonians were beaten and their general killed. Meanwhile Antipater evacuated Lamia, and formed a junction with the defeated army; by the help of which he kept the field, though he dared not venture on another battle. But Craterus arrived from Asia with 12,500 veteran troops, which he placed under the command of Antipater; who, thus reinforced, found himself at the head of 48,000 men, while the Athenians, weakened by the return home of a considerable part of their ill-cemented army, could only muster 28,000 men. An indecisive battle ensued, in which the excellence of their Thesalian horse, which had won the first battle, now saved them from complete defeat; but they felt their inferiority too much to risk another encounter, and sent to treat of peace with Antipater. This, called the battle of Cranon, occurred in August, B.C. 322. Antipater refused to treat with the confederates collectively, but expressed his willingness to come to terms with them severally. This policy was justified by the event, for though the Greeks refused at first to dissolve the alliance, yet the several members of it dropped off by degrees, and left the Athenians and Ætolians, the most obstinate enemies of Macedonia, to secure their safety as they could. Antipater marched with his whole force against Athens; and the citizens, utterly unable to resist, sent Phocion and Demades to sue for peace. They obtained it upon easier terms than were always allowed in Grecian warfare; for he only required two obnoxious persons, the orators Demosthenes and Hyperides, to be delivered up, and granted full security both to person and property, on condition that a Macedonian garrison should be henceforth quartered in Munychia, to guard against a counter-revolution, and that a complete change should be made in the form of government, the democracy being abolished, and all political power vested in a body of about 9000 citizens, who were possessed of property up to a certain amount. He removed a large number of the poorer class (apparently with their own consent) into Thrace, where lands were assigned them. Thus ended the Lamian war, as it is called,

in the autumn of B.C. 322, the year after its commencement. Antipater returned to Macedonia.

The Ætolians were the only members of the confederacy who still held out. In the same autumn, Antipater and Craterus marched against them. They abandoned their indefensible towns; deposited their women and children in their rugged mountains; and collecting their able-bodied men, prepared to hold out in their fortresses, and in those cities which were capable of being maintained. In the first encounters the Macedonians sustained considerable loss; but the superiority of force by degrees prevailed; and the Ætolians, shut up in the mountains, and exposed to the severity of a mountain winter, almost without shelter or food, except that which they won at the sword's point, were almost reduced to despair, when they were relieved by unexpected news from Asia.

For the proceedings in Asia after Alexander's death, we must refer to PERDICCAS: it is enough here to state that the ambition of that general led him to aspire to be Alexander's successor in the throne of half the known world. One of his first steps was to rid himself of Antigonus, whose acuteness and activity he feared; but the latter, fathoming his designs, fled hastily to Antipater, and apprised him of the danger to which he, in common with others, was exposed. To check Perdiccas in time was more important than to punish the Ætolians; and consequently, after concluding a hasty peace with the brave mountaineers, Antipater and Craterus led their army into Asia. They separated: Craterus took the field against Eumenes, satrap of Cappadocia and Paphlagonia, by whom he was defeated and slain; while Antipater marched into Cilicia to meet Perdiccas. But he found no enemy, Perdiccas having been slain in Egypt; and the Macedonian troops, after a short interval, elected Antipater to the office of regent, or protector. These transactions seem to have taken place in the year 321, but there is some confusion as to the chronology. [See ANTIGONUS.] In this new capacity he made a fresh distribution of the provinces: after which he returned to Macedonia, taking with him the king and queen, Arrhidaeus and Eurydice, and leaving Antigonus to conduct the war against Eumenes. This seems to have been in 320.

Antipater held the regency undisturbed till his death, which took place in 318. We hear no more particulars of him, except that he fell into a dangerous illness, and that one of his last actions was to put to death the orator Demades and his son, who had been sent ambassadors by the Athenians to request that the Macedonian troops might be removed from Munychia. Demades had always been on good terms with Antipater, till the Macedonian found, among the papers of Perdiccas, letters written by the orator, exhorting Perdiccas to carry the war into Europe. The regent had not forgotten this: he returned no answer to the address of Demades, but merely made a signal to his ministers of punishment (*τοῖς τεταγμένοις ἐπὶ ταῖς τιμωρίαις*), who put the ambassadors to death without further ceremony.

Dying soon after, Antipater left the regency to Polyperchon, one of the oldest of Alexander's surviving generals. He appointed his son Cassander to be chiliarch,—a term originally meaning captain of a thousand men, but transferred by the Persians to some high officer at court, and adopted in that sense by Alexander, with many other of the Persian customs. Cassander, however, contested the possession of Macedonia with Polyperchon, and finally became master of that kingdom. The last advice which Antipater gave to his successors was, 'never to let a woman interfere in affairs of state.' This was expressly directed against Olympias, and her subsequent conduct fully proved the wisdom of it. Antipater died in his eighty-first year, having enjoyed a high reputation for his talents as a minister, and leaving a character less stained by cruelties and excesses than most of the contenders for empire who sprang up after the death of Alexander. (Diodorus, book xviii., &c.)

ANTI-PATER, son of Antipas, the governor of Idumæa, was himself a native and governor of that province during the high-priesthood of Alexander Jannæus. After that prince's death, his sons, Hyrcanus and Aristobulus, disputed the succession. Antipater was a zealous partizan of the former, who, after a bloody contest, was established in the high-priesthood by Pompey the Great. This favourable issue was very mainly owing to the prudent management of the Idumæan, and he was rewarded by the confidence of his weak master, under whose name he ruled in Judæa.

When Cæsar, during the celebrated siege of Alexandria, was himself besieged in his camp by the inhabitants of that city, Antipater came to his help, and found opportunity to perform good service, and signalize his own courage. Cæsar, in return, obtained for him the citizenship of Rome, and appointed him to the administration of Judæa, which enjoyed tranquillity and prospered under his care. He was poisoned by a Jew named Malchus, A.C. 49, through jealousy of his influence with Hyrcanus. The guilt of the crime was heightened by the ingratitude of the murderer, who had been indebted for his life to the man whom he poisoned, and had received other benefits at his hands. Antipater left four sons, of whom two are known in history: Phasael, governor of Jerusalem, and the infamous Herod, king of the Jews.

These are the two most remarkable persons bearing the name of Antipater; but it is one of common occurrence in antient history. Moreri has articles upon eighteen.

ANTIPATER, L. COELIUS, a Roman historian of the Second Punic War. [See COELIUS.]

ANTI'PATHY, (from the Greek *ἀντίπαθος*, compound of *ἀντι* contrary, and *πάθος* feeling,) properly signifies an involuntary dislike or aversion entertained by an animate being for some sensible object. Thus a man may have an antipathy to particular smells or tastes—a turkey-cock to the colour red, or a horse to the smell of raw meat, &c. There is no doubt that many antipathies are natural, and do not arise from any accidental circumstance: such as the aversion in mankind to the tastes and smells of many drugs, and of bodies in a state of putrefaction. Such natural antipathies may, however, in many cases, be overcome by habit: as in the case of surgeons, who soon learn to conquer the disgust occasioned by the effluvia arising in the dissection of the human subject. Some nations constantly eat food which the rest of mankind would nauseate, as the Esquimaux, who live on whale blubber and train oil. When the Cossacks were in London and Paris, in 1814, they sometimes drank the whale oil from the lamps in the streets: probably an Englishman or Frenchman would, if starving, reject the draught which the Cossack considered as a luxury. It is moreover quite conceivable that individuals may have such physical peculiarities as will cause them to feel pain from impressions on the senses which, to the generality of mankind, are indifferent, or even pleasurable: thus some persons are painfully affected by the smells of certain flowers or perfumes, which are commonly considered agreeable, and are sold as means of sensual enjoyment. Many antipathies, however, are not natural, but acquired, and arise from our associating certain objects with the idea of something terrible or dangerous. Thus people acquire antipathies to spiders, earwigs, wasps, snakes, rats, and other animals, from forming exaggerated notions of their powers of harming mankind; and by encouraging such aversions, they may acquire so great sensitiveness and acuteness in distinguishing these animals by the smell, sight, or hearing, that they may be aware of their presence when other people are unconscious of it. Persons may acquire antipathies to certain kinds of food by having been surfeited with them, or by having been accustomed to eat them for long periods of time, as under a medical regimen during an illness; or because they are made of substances which they consider as unclean, or because they are unfashionable, as being eaten by people whom they think less refined and delicate than themselves. This may not unfrequently be observed in persons of narrow and feeble minds, and more especially in children, in whom such fanciful dislikes ought to be carefully but not harshly corrected. (See Locke's *Essay on the Understanding*, b. ii. c. 33, § 7 and 8.)

Antipathy properly means, as we defined it, a dislike of an *animate* being for some *sensible* object. Its meaning, however, is sometimes improperly extended to *inanimate* beings—a phraseology now nearly obsolete, but which was much used by the antient naturalists, who would, for example, have said that an alkali had an antipathy to an acid, or that water had an antipathy to oil. At other times the word is restricted to animate beings, but is applied to things which are not objects of the senses. Thus it has been said that the mind has an antipathy to certain classes of actions, by which it is meant that it is endued with an innate faculty of distinguishing between right and wrong. [See MORAL SENSE.]

It is sometimes stated that *antipathy* is the contrary of *sympathy*—but this is not strictly true, at least as respects

the use of those two words in modern language. Sympathy means *joint sensibility*, or the feeling of pain or pleasure in consequence of pain or pleasure felt by another sentient being. Thus a person who pitied the misfortunes of another, or who felt delight in the same pursuits, amusements, or studies, as another, would in either case be said to sympathize with him. Sometimes sympathy is applied to the simultaneous irritability of different parts of the body: thus one eye is said to sympathize with the other, when an injury inflicted on one is felt by both. [See SYMPATHY.]

ANTI-PAXO. [See PAXO.]

ANTIPHLOGISTIC TREATMENT, (from two Greek words, *ἀντι* against, and *φλόγος* inflammation,) is the means of removing, or lessening, inflammation, and of obviating its effects. As it would be out of place here to consider fully either inflammation, or its causes, we shall merely state that these last are, either mechanical, as wounds, bruises, &c., or of a more general nature, as atmospheric changes operating on the body from without, or altered conditions of some of the organs or functions of the body, operating within, and influencing, more or less, the rest of the system. The effects of the first set of causes are, primarily, always local, but soon, or later become general, i.e., affect the whole system: the effects of the second set of causes may be, primarily, either local or general; but when local, having a much greater tendency early to become general. The local effects seem to consist in an alteration of the vital action of the part, accompanied with *pain*, *swelling*, and increased *heat* and *redness*. The general effects are disturbance of various functions, most usually a diminution of the functions of secretion, exhalation, and nutrition, or assimilation: the heart's action, the respiration, and functions of the nervous system are also affected, but in different degree and order in different cases. The change of the vital action of the part appears to produce a quickened movement of the blood in the extreme vessels, or capillaries, as they are termed, which are sometimes slightly contracted, though more commonly dilated, so that the blood presently begins to move more slowly, and at length stagnates in the part, as we may see in the white of the eye when inflamed. The blood, too, in the neighbouring capillaries, seems to incline towards the part, while the large arteries leading to it, and ultimately the heart, assume an increased action, which occasions greater frequency and, generally, force of pulse. The consequences of these alterations of the action of the vessels are, the effusion either of some of the constituents of the blood, as the serum or albumen, in their natural state, or their change into substances not found in blood, or any other fluid of the body, in its healthy state. These become the source of further change of structure, as suppuration, ulceration, &c., and the cause of disturbance in the functions of the system, varying with the seat of the inflammation, its intensity, and other circumstances.

The means of preventing or moderating these constitute collectively the antiphlogistic treatment and regimen. We shall here briefly notice the chief of these.

Blood-letting.—We have just stated that one of the effects of inflammation is to produce effusion of the serum or lymph of the blood, the extent of which depends on the quantity of blood which goes to the parts affected. The processes of inflammation, in its earlier stages, may be very certainly restrained or arrested by diminishing that quantity. This is done by abstraction of blood, either local or general. If the inflammation be allowed to proceed, suppuration, ulceration, or other changes, and destruction of parts, according to the texture affected, will ensue. Now abstraction of blood, though it may prevent the extension of suppuration and ulceration to parts not yet affected, is rarely found effectual in checking the formation of pus or matter, where that has been already established. We see then the necessity of the early employment of bleeding, and the other antiphlogistic means, if we desire them to be productive of the greatest amount of benefit. The prejudices and prevailing habits of the people are, however, generally in direct opposition to such beneficial measures; and too often timid practitioners allow their judgment to be overborne by the importunate requests for delay of the well-intending but ignorant relations. Thus the time when these measures would have proved most serviceable is allowed to pass over; and when at last put into practice, their good effects not being so conspicuous, they are not so highly appreciated as they would be, if employed at an earlier period. Indeed, at a very late stage, far from being useful, they are decidedly

hurtful. (See the case of a physician mentioned under the article **ABSTINENCE**.)

During inflammation of shut sacs, or cavities, *i.e.*, those cavities of the body which do not communicate with the external air, and which are lined with *serous* membranes, the disposition to effusion of much lymph, or the albumen of the blood, is greater than in other cases. To prevent this, more prompt and vigorous measures must be used. Modern physicians have ascertained that mercury, especially in combination with opium, has a powerful influence, not only in preventing the effusion of lymph, but in removing it soon after it is effused: an example of this is witnessed when, in the inflammation of the eye, called *is*, the pupil is filled up, and vision prevented by the *is* effused; yet this is speedily removed if a sufficient quantity of mercury be early introduced into the system. This, then, constitutes another valuable antiphlogistic means.

Purgatives.—The quantity of blood in the system, and the amount of serum, may be greatly lessened by the use of purgative medicines, especially the saline purgatives, which generally produce very liquid motions, consisting of a large proportion of serum. These are not only proper, but constitute an essential part of the antiphlogistic treatment.

Nauseants, i. e. such doses of emetic medicines as occasion a constant feeling of sickness, without causing vomiting, reduce the action of the heart, and lessen the tendency to effusion, while they promote the absorption of the fluid already effused. They are, consequently, very valuable auxiliary agents in subduing inflammatory diseases.

Diaphoretics.—The quantity of blood may be diminished, and its acrimony lessened, by increasing the perspiration, or discharge from the skin, which in most cases of inflammation is lessened, and in some altogether suppressed. By this diminution or suppression of perspiration not only more blood is retained in the system, but also those salts and acids which in a healthy state find an outlet by this channel. The means of increasing perspiration are termed diaphoretics, or sudorifics. These, however, seldom produce the desired effect, if there be much heat of surface, *i.e.* of the skin. This must previously be moderated by the use of the means already stated, *viz.*, bleeding and purgatives, and also by the use of

Refrigerants.—These consist of cooling drinks to be taken internally, and cold applications, as cloths dipped in iced water, or vinegar and water, or even ice itself, or evaporating lotions laid upon the part affected. The cold *effusion* is often very serviceable in reducing the temperature and procuring sleep, during which a flow of perspiration, which frequently proves critical, is apt to occur.

It is self-evident that no good can follow the use of any or all of these means of lessening the quantity of blood in the body, if we continue to supply the means of forming it as fast as we remove it. The *diet* of the patient is, therefore, *a*, we might almost say *the*, most important point in the treatment.

During inflammation, as stated above, the functions of secretion and exhalation, as well as of nutrition, are lessened or entirely suspended; there is, therefore, no means of consuming or disposing of the nutritious matter already contained in the blood. How inconsiderate then, and how absurd it is, if life be valued at all, to use means which greatly increase this? Persons do not die of inanition, or from the effects of the absolute privation of food, under many days or weeks, (see the two cases narrated under **ABSTINENCE**,) while thousands, millions, die of inflammatory diseases, in a period varying from a few days down to a few hours. At the beginning of all severe inflammations, there is a failure of the appetite; this intimation on the part of nature, ever watchful for the preservation of her works, cannot be slighted with impunity. Reason and experience strictly enjoin an immediate attention to the diet. Its quantity should be lessened, and in most cases its quality changed. In respect to the reduction of quantity no limit need be placed at the commencement, as it can never be reduced too low; but during convalescence careful regulation of it is necessary, that it may not be insufficient on the one hand, or excessive on the other. Still there is much less likelihood of erring on the side of deficiency, than of excess. The vessels of the part being much weakened, are again easily distended, and the inflammatory process renewed; hence the frequency of relapses. Dr. Baillie has recorded it as the result of his experience, 'that he never observed a person having a relapse of *fever* where it has

not been caused by eating animal food.' It may be well to explain here in what way animal food proves hurtful. During its use the blood requires more frequent purifying by exposure to the air in the lungs, or by respiration. To effect this, not only is more frequent respiration necessary, but also the heart's action is increased, so that the blood is propelled with greater frequency and force, and consequently the distention of the vessels of the inflamed part is increased. The greater frequency of the respiration, occasioned by the greater demand for oxygen, during the use of animal food, is illustrated by the experience of the workmen in diving-bells, who require the air to be renewed much more frequently when living upon animal food and drinking spirituous liquors, than when living on vegetable food and drinking water. For this reason, the pearl-divers of Ceylon, who live exclusively on rice and other vegetables, can remain much longer under water, without requiring to come to the surface to breathe, than any Europeans who live on a mixture of animal and vegetable food. Animal food and spirituous or fermented drinks must be strictly interdicted at the commencement of inflammation, and their use be avoided till the permission of the medical attendant be deliberately and voluntarily given; previous to which mild, farinaceous food, and diluent drinks, should constitute the only diet.

Rest.—A person in a horizontal position respire less frequently than when in an upright position; the heart also pulsates less frequently. In every case of inflammation affecting the system generally, the patient should be confined to bed; and as there is mostly diminished power of the muscular system, all unnecessary exertion should be avoided. Numerous visitors should not have access to the sick-room; for speaking, which requires the exercise of the respiratory organs, fatigues the patient, and quickens the circulation. Besides this, the air is vitiated by the respiration of visitors. A supply of pure and cool air is requisite in all inflammatory complaints, but especially fevers, both for the benefit of the patient and the safety of others.

The repose of the mind is as essential as that of the body. All causes of anxiety should, when possible, be removed, and cheerful looks be put on before the patient, both by the physician and the attendants, in order that, as far as practicable, he may be inspired with confidence and entertain hopes of recovery.

This is a very brief outline of the means termed antiphlogistic, by which we attempt to restore both the part affected and the system generally, to the natural and healthy state, when labouring under an inflammatory attack. The special application will be given as each disease falls under notice, and we need not here do more than endeavour to impress upon every one a conviction of their importance. 'Under favourable circumstances inflammation is more completely under the control of remedies than any other disease; and nevertheless, it is more or less concerned in producing a very large share of the mortality in every part of the world.' (See Alison's *Outlines of Pathology*.)

ANTIPHON, the son of Sophilus, and the oldest of the Athenian orators, who are generally known under the denomination of the 'ten,' belonged to Rhamnus, a *demos* or township of Attica, and was born about B.C. 480, the year of the great victory over the Persians. He was a contemporary of the famous Gorgias who visited Athens, and somewhat younger than this sophist, but there is no distinct proof that he was his pupil, though it is sometimes asserted; nor are we told who was his master. In course of time he opened a school of rhetoric, and numbered among his pupils Thucydides, the historian of the Peloponnesian war, who, in a passage of his eighth book (chap. lxviii.), has commemorated the talents of his master, and recorded almost the only completely trustworthy event in his life. The opinion that Thucydides was the master of Antiphon appears to us untenable. (See Van Spaan). It was the profession of Antiphon to write speeches for persons who had either to defend themselves in courts of justice, or wished to proceed against others, and also for those who had to address the public assemblies. According to tradition, he was the first who became a hired advocate of this description, though he merely wrote speeches, and never delivered any except on one occasion, when he was himself concerned. According to several authorities, he is the oldest writer who composed speeches for the courts of justice; no speeches of this character of higher antiquity being preserved. (Diodorus, Photius, &c.) There is no distinct proof, that is satisfactory, of his being early engaged in public service.

the silence of Thucydides, as to all his life previous to the events related in his eighth book, proves that he was not engaged in any important military capacity, at least during the Peloponnesian war. It has been conjectured that he is the archon Eponymus, or chief archon of Athens (Ol. xc. 3. or B.C. 418) mentioned by Diodorus (xii.) In the year B.C. 411, and in the latter part of the Peloponnesian war, a revolution was effected by which the Council of Five Hundred was abolished, and all political power was vested in a body of four hundred. [See ALCIBIADES, i. p. 279; PELOPONNESIAN WAR]. Antiphon, who never had come forward as a public man, did not show himself on this occasion, though he was the real author of the revolution, and Pisanter, who appeared as spokesman, was merely his agent. Shortly after this change, Antiphon and Phrynichus with ten others were sent to Lacedæmon to make peace on any terms that were tolerable. The ambassadors returned without effecting their object. Discontent grew stronger; Phrynichus was assassinated in the public place, a counter-revolution was immediately effected, and Alcibiades was recalled from exile. Immediately after the event, Antiphon, now seventy years of age, was tried for his life on a charge of treason to the state; he made, according to Thucydides, an admirable defence. His sentence (see the decree quoted by *Cæcilius in the Life of Antiphon*, attributed to Plutarch) was death; his property was confiscated, his house was pulled down, and the site was marked by stones bearing the inscription, Antiphon the Traitor. Antiphon, says Thucydides, was inferior to no Athenian of his time in virtue; he had also the greatest talents for conceiving any plan, and equal talent in expressing his conceptions. It is singular that Thucydides says nothing about the sentence or the death of Antiphon.

There were at least five or six other persons in antiquity who bore the name of Antiphon. Several of these different persons have been confounded in the rambling life of Antiphon attributed to Plutarch. One of them was a sophist, and appears to have been the author of a work on *Truth*, in which it is conjectured, from a few references to it in extant writers, that some of the leading doctrines afterwards promulgated by Epicurus were announced by Antiphon. The orator, according to some accounts of very little credit, was executed under the tyranny of the Thirty after the close of the Peloponnesian war. (See Xenophon, *Hellenic*. ii. 3, 40; and Van Spaan, *Dissertatio de Antiph. Orat.*)

Antiphon wrote a treatise on *Rhetoric*, which is lost. Sixty orations were once extant under the name of Antiphon, but Cæcilius considered twenty-five of them to be spurious. At present there are fifteen extant, three of which are on subjects which were matters of judicial investigation, and are well worth reading. The other twelve are distributed into *tetralogies*, or fours, each set of four being on the same subject; they are merely rhetorical exercises, such as those to which Cicero alludes when speaking of Antiphon. (*Brutus*, chap. xii. 6.) The language of this writer is often obscure, and the style does not appear to us to merit the praise bestowed on it by some of the Greek critics. The orations of Antiphon are in the seventh volume of Reiske's collection, and in the first of Bekker's edition of the *Orators*. They are also in Dobson's collection, vol. i., with Van Spaan's *Dissertation*, &c. The text of Bekker is the best.

ANTIPHONARY, ANTIPHONARIUM, in music, the book wherein the *antiphonies* were written. (See **ANTIPHONY**.) By an order of Archbishop Winchelsey, made in 1305, every church in the province of Canterbury was obliged to be furnished with an *antiphonary*, among other equally expensive books; and Spelman states, that in 1424 two *antiphonaries* cost the little monastery of Crabhuse, in Norfolk, twenty-six marks, which he says was equal to 52*l.*, according to the value of money in his time. We may, therefore, calculate the expense of a single one at not less than from 90*l.* to 100*l.* of our present money.

ANTIPHONY, in music, (*ἀντιφωνία*, alternate singing,) the antient name for a kind of anthem, the verses of which were chanted by each side of the choir, alternately.

The fathers of the church pretend that the method of antiphonal singing was revealed to St. Ignatius in a vision, who taught it to the Greeks. St. Ambrose introduced it in the western churches about the year 374. The chanting of the psalms in our cathedrals is a close imitation of the antient antiphony.

ANTIPODES, a term from the Greek, meaning

literally those who stand feet to feet, as is the case with the inhabitants of two opposite points of the globe. Previous to the establishment of the rotundity of the earth, and during the centuries of discussion which took place upon this point, the existence of antipodes was the theme of constant ridicule in the mouths of the opposers of the globular figure. The sentiments of Lactantius, *De Falsâ Sapientiâ*, cap. 23, may be taken as a fair specimen of the common objections. He asks, 'Is there any one foolish enough to think, that there are men whose feet are higher than their heads? with whom those things that we place upon the earth hang downwards from the earth? who have trees and vegetables turned upside down, and rain and snow falling the wrong way? Will any one henceforward place the hanging gardens among the seven wonders of the world, when the philosophers make hanging seas, and fields, and cities, and mountains?' The confusion that here takes place between the words upwards and downwards will be now universally apparent, but was not so in the time of Lactantius, who lived A.D. 311; who, had he simply confined himself to the assertion, that the existence of antipodes could not be demonstrated, and treated it as a philosophical speculation, possibly true, but probably false, would have been justified by the general state of knowledge then existing. But not so when he asserts that he can prove the thing to be impossible, and professes that he sees no alternative, but supposing its defenders to be either joking, or intentionally lying. The French *Encyclopædia* is incorrect in stating that he appeals to the sacred writers as deciding the point.

Two *antipodal* points of the earth have the same number of degrees of latitude, one north and the other south, unless one of the points be on the equator, in which case the antipodal point is the opposite point of the equator. Their longitude differs by 180° or 12 hours, if we reckon longitude all round the globe; but if we use east and west longitude, the two longitudes must together make up 180° or 12 hours, one east and the other west. For example, the antipodes of a point in 22° north latitude and 60° east longitude, are in 22° south latitude, and 120° west longitude. We here insert, in opposite columns, the names of a few places which are nearly antipodal.

London	{ Antipodes Island, S.E. of New Zealand.
Nertchinsk	{ Falkland Islands.
Nankin	{ Buenos Ayres.
Mouths of the Amazon	{ Moluccas.
Bermudas	{ Swan River.
Quito	{ Middle of Sumatra.
Lima	{ Siam.
Timbuctoo	{ Friendly Islands.
Azores	{ Botany Bay.
Spain	{ New Zealand.

Antipodal places have the same climate, so far as that depends merely on latitude, but have all the seasons, days and nights completely reversed. Thus, noon of the longest day at the Bermudas is midnight of the shortest day at the Swan River. The remark as to the seasons of course does not apply to antipodal places on the equator.

When it is noon at any one place, it is midnight at the antipodes, and sunrise and sunset are reversed in the same manner. But we may ask, when it is noon on Friday at London, is it *Friday* night or *Thursday* night at Antipodes Island? There is no rule to determine this; we might call it either one or the other with perfect consistency. If two travellers were to set out from London for Antipodes Island, one of whom should go eastward through Europe and Asia, and the other westward through America, whatever time they might respectively take for the voyage, they would not agree in naming the day of their meeting. If they meet at the moment when Saturday morning begins at London, that is, at midnight between Friday and Saturday, in which case it will be noon at Antipodes Island, the eastern traveller will call it Saturday, and the western Friday. The reason is as follows: the traveller who goes east, sets out to meet the sun in the morning, and will therefore have that luminary on the meridian (that is, he will have noon) sooner than if he had remained stationary. He therefore shortens his day a little, or, to him, the same absolute time is a larger proportion of the interval between two noons, and by thus gaining a little each day, he is 12 hours before London when he reaches the antipodes. The western traveller, on the contrary, turns his back on the sun in the morning, which is therefore on his meridian later than it

would have been had he remained stationary. Before he reaches the antipodes, he has lost twelve hours; but the other traveller has gained as much, which together makes a whole day's difference in their reckoning. The reader who examines this question will find that, the day always beginning at noon or midnight, it is impossible that the whole world should have the same reckoning. We see, therefore, that the reckoning of a place will depend upon the direction from which the first settlers approached it, and any one who should afterwards join them from the contrary direction would differ from them by a day. Thus, when Dampier reached Mindanao from the west, he was a whole day behind the Europeans he found there, whose ancestors had travelled from the east. And Varenus, a Dutch physician, who travelled in the east about A.D. 1670, states that the Portuguese at Macao were always a day in advance of the Spaniards at the Philippines. The fact was, that the Portuguese came by the Cape and India, and the Spaniards from their American possessions.

Before we conclude this article, we must remark that it would be useful in teaching geography, if the maps of the southern hemisphere had the northern hemisphere drawn upon them in faint outline, reversed, in such a way that any one might perceive, at a glance, to what point of the northern hemisphere any point in the southern is antipodal. There is comparatively so little land in the southern hemisphere, that such an addition would not crowd any part of the map too much.

ANTIQUARIES, SOCIETY OF. Mr. Gough, in the introduction to the *Archæologia*, fixes what he considers to have been the earliest foundation of the Society of Antiquaries to the fourteenth year of the reign of Queen Elizabeth, A.D. 1572; when a few eminent scholars, under the auspices of Archbishop Parker and Sir Robert Cotton, united their efforts for the preservation of the antient monuments of their country. The members met for near twenty years at the house of Sir Robert Cotton, and as early as 1589 determined to apply to Queen Elizabeth for a charter of incorporation; a manuscript still remaining in the Cottonian collection (Titus, b. v. fol. 184) preserves the reasons which were urged at this time in support of the petition. But whether the petition was ever presented, or what was its success, does not appear. The writer of the life of Carew, the Cornish antiquary, says, their hopes were frustrated by the queen's death. This society, however, admitted members till 1604; about which time King James I., alarmed for the arcana of his government, and as Hearne conceived for the Established church, thought fit to dissolve it. An attempt to revive the society was made in 1617, in an application for a charter, through the Marquis of Buckingham; but this also appears to have failed.

From this time to the beginning of the eighteenth century the society ceased to exist; or as Mr. Gough expresses it, remained in abeyance.

In 1707, a number of gentlemen, attached in a similar manner to the study of our national antiquities, agreed to meet weekly for the same purposes as the former society, on a Friday evening, at the Bear tavern in the Strand. Among these were Humphrey Wanley; Mr. John Talman; John Bagford; Peter Le Neve, Norroy; Mr. Holmes, the keeper of the Tower records; Madox, the Exchequer antiquary; Mr. Batteley; Mr. William Elstob; Stebbing, the editor of Sandford's *Genealogical History*; and Mr. Sanderson, clerk of the Rolls. Le Neve was at this time president. In 1708 they removed their meetings to the Young Devil tavern, in Fleet-street, and soon after to the Fountain tavern over against Chancery-lane. Here they were joined by Samuel and Roger Gale, Dr. William Stukeley, Mr. T. Rymer, Browne Willis, and Anstis. The plan of their pursuits, comprising every thing which such a body of men might be expected to do for the illustration of their national antiquities, appears to have been drawn out for them by Humphrey Wanley.

In 1717 the members re-founded, or rather re-constituted, their society, and made their first election of officers; Peter Le Neve, Esq., was president, Dr. William Stukeley, secretary, Mr. Samuel Gale, treasurer, and Mr. John Talman, director. At this time also George Vertue, the engraver, became an active member. The number of members was limited to a hundred, and no honorary members were allowed. The minutes of the society begin January 1, 1718; whence it appears that every member, or whoever was admitted to be present, brought from time to time whatever they had of their own, or their friends, that was curious or

uncommon: as coins, medals, seals, intaglios, cameos, manuscripts, records, rolls, genealogies, pictures, drawings, printed books, extracts, or even memoranda; a few produced dissertations. In 1727 the society removed to apartments in Gray's-Inn, and afterwards to the Temple; and, for a very short period, seemed to decline. In 1728, however, they renewed their meetings at the Mitre tavern in Fleet-street, fixing them to Thursday evenings, after the Royal Society had broken up. In 1753 they removed from the tavern to a house of their own in Chancery-lane.

In 1750, it was unanimously resolved to petition the king for a charter of incorporation on the plan formed in 1717, with improvements. This, by the concurrence of the Earl of Hardwicke, then lord chancellor, was obtained in the following year, when his majesty having declared himself 'Founder and Patron,' the society became incorporated by the name of 'President, Council, and Fellows of the Society of Antiquaries of London;' they were empowered to have a body of statutes and a common seal, and to hold in perpetuity lands, &c., to the yearly value of 1000*l*. The council to consist of twenty-one persons, including the president, and to be elected yearly with the other officers. The first council named in the charter, bearing date November 2, 1751, pursuant to the powers therein given them, re-elected as members the other persons not particularly specified. In 1754 the society determined to have two secretaries. In 1781 the society removed from Chancery-lane to Somerset-place, where his majesty King George III. had been graciously pleased to grant to them, as well as to the Royal Society, appropriate apartments. The Society of Antiquaries held its first meeting there on January the 11th that year.

The anniversary of the society is held on the 23rd of April, when ten of the twenty-one persons of whom the council consist are annually changed. The election of members is by ballot; a certificate having been signed by three or more fellows, is previously exhibited for six successive meetings (including those of proposition and election), except in the cases of peers, members of the privy council, and judges, who may be proposed by a single member, and balloted for upon the same evening. The election is determined by a majority of two-thirds. Every member pays an admission fee of eight guineas, and four guineas a year; or an additional sum of forty guineas to the admission fee, to be constituted a member for life. The society's meetings are held on Thursdays from seven o'clock in the evening till nine, in apartments adjoining to those of the Royal Society, in the front building of Somerset-place. The Royal Society's meetings succeed those of the Antiquaries on the same evenings; and the sessions of the two societies coincide as to time, beginning with the third Thursday in November, and ending with the third Thursday in June. The total number of members of the Society of Antiquaries, A.D. 1833, is 753. The presidents, since the incorporation of the society by charter, have been:—1751, Martin Folkes, Esq.; 1755, Hugh Lord Willoughby, of Parham; 1765, Charles Lyttelton, LL.D., Bishop of Carlisle; 1768, Jeremiah Milles, D.D., Dean of Exeter; 1784, Edward King, Esq. (temporarily elected by the council); 1784, George Ferrars Townshend, Baron de Ferrars of Chartley, afterwards Earl of Leicester and Marquis Townshend; 1812, Sir H. Charles Englefield, Bart. (temporarily elected by the council); 1813, George Earl of Aberdeen, who is still president.

By an act of parliament, 5 Geo. IV., chap. 39, the President of the Society of Antiquaries for the time being is declared to be an official trustee of the British Museum.

The publications of this society as a body have been:—1. *Vetusta Monumenta*, 4 vols. folio, 1746—1815, vol. v. not completed; and vol. vi., commencing with seventeen coloured plates of the Baieux tapestry. 2. *Five Dissertations*: one on Doomsday Book, and one on Danegeld, by P. C. Webb, Esq.: two on the Heracleian Table, by Mr. Webb and Dr. Pettingal: one on the Tascia, by Dr. Pettingal: quarto 1756-63. 3. Folkes's *Tables of English Silver and Gold Coins*, with plates, quarto, Lond., 1763. 4. *Archæologia*; or *Miscellaneous Tracts relating to Antiquity*, 25 vols., quarto, Lond., 1770—1833. 5. *Liber Quotidianus Contrarotulatoris Garderobæ, anno regni Regis Edwardi primi vicesimo octavo*, A.D. 1299, 1300 (from a MS. in the society's possession), quarto, Lond., 1788. 6. *A Collection of Ordinances and Regulations for the Government of the Royal Household, made in divers reigns, from King Edward III. to King William and Queen Mary*, quarto, Lond., 1790.

7. *The Military Antiquities of the Romans in Britain*, by the late Major General Roy accompanied with Maps, Plans of Camps and Stations, &c., folio, Lond. 1793. 8. *Some Account of the Collegiate Chapel of St. Stephen at Westminster*, by John Topham, Esq., folio, 1795, with additional Plates, described by Sir H. C. Englefield, folio, 1811. 9. *Account of the Cathedral Church of Exeter, with Plans, Elevations, and Sections*, by Dean Lyttelton and Sir H. C. Englefield, folio, 1797. 10. *Account of the Abbey Church of Bath, with Plans, &c.*, folio. 11. *Some Account of the Cathedral Church of Durham*, folio, 1801. 12. *Some Account of the Cathedral Church of Gloucester*, folio, 1809. 13. *Some Account of the Abbey Church of St. Alban*, by the late Mr. Gough, with Plans, Elevations, &c., folio, 1813. 14. *Cædmon's Metrical Paraphrase of Parts of the Holy Scriptures, in Anglo-Saxon, with an English Translation, and Notes*, by Benj. Thorpe, F.S.A., octavo, Lond. 1832. This last work is the first of a series of publications of Anglo-Saxon and early English literary remains, intended to be edited under the superintendence of a committee of the Society. Lavamon's *Translation of Wace's Chronicle of the Brut*, to be edited by Sir Frederick Madden, in two volumes, will form the second work of the series.

Besides the works above-mentioned, the society have published seven historical prints of large size, accompanied by five historical dissertations. The prints are, 1. *Le Champ de Drap d'Or*; or, the *Royal Interview of Henry VIII. and Francis I. between Guisnes and Ardres*, A.D. 1520. 2. *Francis I.'s attempt to invade England, 1545*. 3. *The Embarkation of Henry VIII. at Dover, 1520*. 4. *The Procession of King Edward VI. from the Tower to Westminster*. 5. *The Departure of King Henry VIII. from Calais, July 25, 1544*. 6. *The Encampment of King Henry VIII. at Marquison, July, 1544*. 7. *The Siege of Boulogne by King Henry VIII. 1544*. Also two sets of historical, and some miscellaneous prints, (including Aggas's *Plan of London*,) engraved by Mr. George Vertue, now the property of the Society: with a portrait of *Sir John Hawkwood*; and four views of the *Ruins at Stanton Harcourt in Oxfordshire*, drawn and etched by Simon Earl Harcourt.

ANTIQUES, (from the Latin *antiquus*, antient,) a term used in the English language to designate 'antient works of art.' But this definition may be objected to as not sufficiently precise (see **ANCIENTS**). The term properly refers to works of Grecian art in sculpture, bas-relief, engraving of gems, medals, &c. As these arts flourished in the states of Greece, and also under the Roman Empire, (though most probably they were always successfully cultivated chiefly by Greeks,) it is not possible to find any precise chronological limits that shall determine whether a work of art belongs to the *antique* or not. Still, as there was under the Roman Empire a great and progressive deterioration in the arts above alluded to, until in more recent times they have been again improved, it is clear that many works of considerable antiquity cannot be classed under the head of *antiques*; for by the term *antiques* we understand, in general, works that have decided merit, and may serve as models for imitation; or they are at least works of art that serve to illustrate and explain those antient authors whose writings, by common consent, are allowed to be deserving of study.

ANTIQUITIES. This term seems not to have its meaning very accurately fixed in our language. It is sometimes used as synonymous with *antiques*; but generally it has a wider signification. Books that treat of Greek and Roman antiquities, to which the term is commonly confined, treat not only of works of art, but of political constitutions, judicial and legislative forms, religion, architecture, domestic manners, naval and military affairs, weights and measures, mode of reckoning time, &c. Some of these branches of inquiry are capable of illustration, both from antient writings that remain, and from existing works of antient art; some can only be known to us from the study of antient writings. This extensive signification of the word *antiquities*, though certainly not very precise, still keeps up a distinction between *antiquities*, as thus understood, and the *political history* of the Greeks and Romans, and the study of the Greek and Roman *languages*. Yet we think the common use of the word *antiquities* in this country a bad one, and we should prefer seeing it limited more closely.

The study of *antiquity* is generally understood to mean the study of all that belongs to the Greeks and Romans, of all the knowledge concerning them that has been trans-

mitted to our times. the word *philology* is used in this sense in Germany. Under the general term *antiquity*, then, we may class all the several subjects which it comprehends; such as antient forms of polity, antient systems of philosophy, of astronomy, with political history, antient architecture, sculpture, poetry, &c.

With the increase of our knowledge of the durable memorials which man has left behind him in various parts of the earth, we have applied the term *antiquities* to the monumental remains and to the works of art of numerous nations. We now speak of Egyptian, Persian, Hindoo, Peruvian, and Mexican antiquities, when referring to the works of art existing in these countries, or collected in European museums. The terms Egyptian and Hindoo antiquities, when not specially used with reference to works of art, are also understood as comprehending history, mythology, &c. But unless some qualifying word is prefixed to the term *antiquities*, we generally understand by it, Greek and Roman antiquities.

ANTIQUITY. [See **ANCIENTS** and **ANTIQUITIES**.]

ANTIS. A portico is said to be *in antis* when columns stand in a line, in front, with the antæ or projecting ends of the side walls of the temple or other building. If in the plan of the temple of Ægina [see **ÆGINA**] the external peristyle or surrounding range of columns were removed, the pronaos and opisthodomus, as there indicated, would be porticoes *in antis*,—not prostyles. There is a very good example of the portico *in antis* in North-Audley-street, London, forming the entrance to an episcopal chapel there.

ANTI'SCII, an old astronomical term derived from the Greek, signifying those whose shadows are in opposite directions. It is applicable, during part of the year, to any two persons, one or both of whom reside within the tropics, and during the whole year, to any two persons, neither of whom lives within the tropics, and both in different hemispheres.

ISCORBUTICS, from *anti*, against, and *scorbutus*, a barbarous word, intended as the Latin for *scurvy*: the remedies, real or reputed, against scurvy. The term *scurvy* is popularly, but incorrectly, given to two distinct diseases, which arise under different circumstances, spring from different causes, present few symptoms in common, and are cured by means not only unlike, but diametrically opposite. The confusion has crept in owing to the skin in true scurvy occasionally, but by no means invariably peeling off in scales or *scurf*; while in the other disease of diseases, improperly termed scurvy, desquamation, or other affection of the skin, is an essential and invariable symptom, the portions or scales of which being commonly called *scurf*, the adjective *scurfy* has insensibly come to be used as a substantive, and to be applied indiscriminately to the two diseases. The one occurs mostly at sea, hence called sea-scurvy, and is owing to temporary causes, capable of affecting persons of any constitution; the other occurs mostly on land is owing to more permanent causes, and is always connected with a peculiar constitution. The necessity of making this distinction is manifest, since the remedies for the one disease are few and certainly efficacious, the medicines for the other are multifarious and generally very inefficacious. The circumstance points out an essential difference between the two disorders; and it is of the means of curing the former of these that we here chiefly intend to speak, adding only a few remarks upon those for the latter.

The importance of the naval force to the safety, commerce, and maritime strength of this country, would justify a very lengthened inquiry into the causes of this disease and the means of prevention and cure, if it now prevailed among seamen to the extent that it once did, and if it continued to impair the strength of the main bulwark of our national defence. The almost total eradication of the malady, however, renders such investigation altogether unnecessary, farther than as a subject of interesting and instructive contemplation.

Of the degree to which this complaint existed, a few instances will serve as proofs. In 1593, Admiral Hawkins stated it to be consistent with his personal knowledge that 10,000 men had perished of scurvy; at a much later period Commodore Anson, in the course of his voyage round the world, lost above four-fifths of his men, and when he arrived at Juan Fernandez, of the two hundred men then surviving, eight only were capable of duty. An entire crew has sometimes fallen a victim to it, and the ship been left without a single hand to guide it through the waters. This happens

in the case of the Spanish ship *Oriflamme*, in which the whole crew perished, and in this state she was discovered with the dead bodies on board.

As a means of contrast it may be stated that, in the year 1780, there were admitted into the Royal Haslar Hospital at Portsmouth, under the care of the physicians, 8143 cases of disease, of which scurvy formed 1457; while, during four years, namely, 1806, 1807, 1808, and 1809, into the Royal Naval Hospital at Plymouth, there were admitted under the care of one of the physicians 1984 cases of disease, of which two only were scurvy. During nine years of warfare, namely, between 1778 and 1795, the number of men voted by parliament for the naval service was 745,000; of these, 189,730, a large proportion of which number consisted of men affected with scurvy, were sent sick to hospitals or on shore; while, during nine consecutive years of warfare, namely, from 1796 to 1806, the number of men voted for the naval service was 1,053,076, of whom there were sent sick only 123,949, a difference mainly owing to the disappearance of scurvy.

Let us inquire what were the causes which produced this dreadful disease, and formerly rendered it so frequent; and what are the circumstances which have contributed to its abatement or disappearance, and which now secure to our seamen so gratifying an immunity from it. Before doing this, it will be proper to give a short detail of the symptoms. Under the influence of the concurring causes, an individual began to lose his natural and healthy colour: the skin, first of the face, and afterwards of the rest of the body, became pale, and assumed a bloated appearance; the lips, instead of a rich vermilion, acquired a greenish tinge: indeed, the countenance in this disease is always very much depressed, indicating a corresponding state of mind. The patient is conscious of weariness, and is averse to exertion; and when that of a bodily kind is attempted, his unfitness for it is seen by the weakness of the knees (which often become stiff and contracted) and of the whole muscular system, greatly increased frequency of breathing following the least effort. The skin is dry, sometimes rough, but more generally smooth and shining, with spots of a red, blue, or black appearance, according to the length of time that the blood has escaped from the vessels, which is the cause of these stains. The limbs become dropsical, the gums spongy and swollen; ulcers or any sores, cuts or scratches, bleed profusely, and cannot be healed; even old ulcers break out anew, and broken limbs, apparently firmly united, separate again, and cannot be reunited so long as the disorder continues. The blood when drawn scarcely coagulates, but remains loose and flabby; yet during the whole of this state the appetite generally continues good. These symptoms all denote great debility, which is occasioned by a peculiar alteration of the blood, and is produced by the causes we have now to mention.

One of the most extensive and powerful causes of debility is constant exposure to a cold and damp atmosphere. The construction of ships was formerly such that the sailors were continually exposed to the operation of this cause, which was further aided by the unwholesome exhalations from the bilge-water, the sand used for ballast, and the remains of animal and vegetable matter which were strewed about the ship: no means of removing or lessening these causes existed, from the utter absence or imperfect nature of the means of ventilating the ship, or washing it, without increasing the dampness. The sailors were also very inattentive to personal cleanliness, were unprovided with soap, and were too insensible of the advantage of changing their dress when wet, and were also without the opportunity of changing or washing and airing their bedding. The measures adopted by Captain Cook, on the occasion of his second voyage round the world, were very similar to those since universally pursued. Out of 318 men, during a voyage of three years and eighteen days, throughout all climates, from fifty-two degrees north to seventy-one degrees south, he lost only one. For this, in the year 1776, he received from the Royal Society the Copley medal. (See Kettler's *Life of Cook*, 1788, p. 315.)

By the change effected by Sir Robert Seppings in the construction of ships, and the substitution of iron instead of sand for ballast, and of iron tanks instead of casks for water; by the efficient means he has devised for ventilating the ship, without exposing the persons of the sailors to cold; and by the employment of portable iron fire-places in different parts of the ship, as well as by a change of bedding, and

a proper allowance of soap to each sailor—these debilitating causes no longer exist, or are rendered powerless.

Another cause of debility was either excessive fatigue or deficiency of proper and regular exercise; the former cannot always be avoided, as in the case of much bad weather, when the labour of all hands is increased, or great sickness among the crew, which requires more exertion on the part of the healthy. But deficient exercise can always be avoided by the officers finding employment, or inventing amusing occupation, for the sailors, and above all for the marines, who, having less active duty in the ship, were the most frequently attacked by scurvy. Intemperance also greatly contributed to prepare the system for a scorbutic attack, but this vice is now much repressed.

None of these causes singly, nor indeed all of them combined, are adequate to produce scurvy, unassisted by some specific cause, which cause is to be found in the *diet*. The diet of seamen during long voyages was formerly merely salted meat and biscuit; fresh animal food or recent vegetables formed no part of it. It was also often deficient in quantity.

Salt, if taken in moderation, facilitates digestion, but if in excess, hinders the digestion of the food, even of fresh meat and vegetables; when employed as a means of preserving meat, it hardens it, and impairs its nutritive power, as well as renders it more difficult to digest. Such meat is less nourishing, but more stimulating, than fresh meat, and its long-continued use produces what may be termed the *disjunctive* inflammation, owing to which old wounds and ulcers break open, and fractured bones separate after reunion. The salt seems to be pernicious in a two-fold way, first, by lessening the nutritious power of the meat; and secondly, by its stimulating properties. The former of these, unaided by the latter, is sufficient to produce scurvy, if the predisposing causes of cold, moisture, and imperfect or excessive exercise be in operation. The diminution of the *quantity* of food, and not its *quality*, was the principal exciting cause of scurvy in the *Milbank Penitentiary* in 1819. [See *ABSTINENCE*.]

In what way the absence or inadequate supply of fresh vegetables operates has not been ascertained. That the deficiency of this article of nutriment has a large share in producing scurvy is established by the facts, that before the extensive introduction of esculent vegetables into Britain, scurvy was almost as common on land as at sea; and also by the rapid disappearance of scurvy from among the crews of ships, so soon as they procure a supply of vegetable articles of diet of any kind, but more particularly those belonging to certain tribes of vegetables,—as the hesperidæ or aurantiacæ (the orange tribe), the grossulariæ, or gooseberry tribe, which are all acid vegetables; and the crucifæræ, or mustard tribe, containing cabbages (whence sour-kraut is prepared) and the well known scurvy-grass, which are alkaliescent vegetables; the conifæræ, some of which yield spruce; &c.

These vegetables, or the articles prepared from them, constitute the *antiscorbutics*, or means of preventing and curing sea-scurvy; but they are not all of equal value, some far surpassing the others in efficacy. Those are the least valuable in which no vegetable acid greatly predominates, so as to impart to them an acid or acidulous taste. Hence the crucifæræ are not so useful in their natural state, as the name of *scurvy-grass*, bestowed on one of them, would seem to indicate; but when by their fermentation, as that of cabbages to form sour-kraut, a vegetable acid (acetic acid? or vinegar) is produced, they rise in the scale of antiscorbutic power. But at the head of all, the hesperidæ deserve to be placed, the members of which contain citric acid: accordingly any of the species may be employed; but the most powerful belong to the genus *citrus*, especially the *citrus limonum* (Risso), the well-known lemon, since the introduction of which into the navy, in 1796, scurvy has almost ceased. It may be used in various ways; the best is in the form of the fresh fruit, sucked by the patient: but in the absence of this, lemon-juice may be employed, and this is the usual mode in the naval practice. Several gallons of it, having a tenth-part of spirit of wine added to preserve it, are supplied to each ship, and in about a fortnight after leaving port, its use is begun; each sailor is allowed one ounce of it and one ounce and a half of sugar to mix with the grog, or in many instances with wine, a stated quantity of which is granted in lieu of a certain quantity of spirits, which is withdrawn. This has

the effect of almost invariably preventing scurvy affecting any of the crew; but should symptoms of the disease begin to show themselves, they quickly disappear by an increase of the quantity of lemon-juice. Citric-acid, which has been crystallized and again dissolved in water, is not so efficacious; neither is vinegar, nor any other vegetable acid, such as tartaric, or malic, so useful, though the fruits containing them (unripe gooseberries, tamarinds) are the best substitutes for lemons, when these cannot be procured.

No one, as far as we know, has attempted to explain how these vegetable acids produce their beneficial effects. It may be remarked, however, that all acid fruits have a very cooling and soothing effect in many complaints; they are among the most useful refrigerants, and often sit on the stomach and restore its power, when in a very irritable or weakened state. This is particularly the case where the powers of the stomach and nervous system have been much impaired by intemperance, especially from the abuse of spirituous liquors, in which tartaric acid is eminently serviceable; even during a fit of intoxication, a draught of vinegar will restore the drunken man to his senses more speedily than any other means. These acids appear to exert a very considerable vital action on the system generally, but especially on the nervous centres. Further, lemon-juice and vinegar exercise a chemical influence on many articles of food difficult of digestion, as veal; hence the practice of serving these articles to table, accompanied by one or other of these acids. If the salt has rendered the meat hard and difficult of digestion, may not these acids produce some change in it, rendering it less so by their chemical properties, as well as by their general action, heightening or increasing the vitality of the stomach, and consequently its power of extracting the nourishment? Some local effect is produced by the direct application of lemon-juice, as slices of lemon placed on the ulcers hasten the healing processes.

Mineral acids, such as elixir of vitriol, are found less useful, though they and other strengthening medicines, such as sulphate of quinine, may occasionally prove serviceable, when lemon-juice is wanting, or fails in effecting a cure, which has happened in some very rare instances. An instance occurred in 1822, on board his majesty's ship *Leander*, where, however, probably some undiscovered cause of scurvy existed about the ship; for we cannot suppose the want of success to have depended on peculiarity of constitution where so many men resisted the curative influence of the medicine. (See also Bampfield on *Tropical Dysentery*.) Chloride of soda appears to have some claim to a favourable regard; but at present we have too little experience of it, in this respect, to speak positively of its antiscorbutic power.

In addition to the lemon-juice, ships intended to be sent on long voyages are supplied with animal food so prepared, as to be almost as fresh at the end of six years, as if it had been killed but a few days and dressed the day previous to its being used. This valuable discovery, which tends so greatly to lessen the inconvenience of a sea-life, as well as to secure the health of those devoted to it, was made by Mr. Appert: the mode of effecting it, and the principle on which it depends, will be explained under ANTISEPTICS.

After every fair degree of merit is assigned to other means and articles, the main instrument of banishing scurvy from among the number of diseases incident to a sea-life has been the liberal use of lemon-juice. The nation owes a deep debt of gratitude to those who effected its universal introduction into the naval service, and who yet live to witness the beneficial effects of their enlightened views; these are Earl Spencer, who was first lord of the Admiralty in 1795, and the benevolent, and now venerable, Sir Gilbert Blane, physician to the fleet, and at the head of the Navy Medical Board in 1795. But for their exertions our navy could not, during the twenty years of the war which followed that date, have achieved those victories which have rendered our country so illustrious. Had the mortality in the navy, throughout these twenty years, been equal to what it was in 1779, the whole stock of seamen would have been exhausted. (See paper on the comparative health of the British navy, by Sir Gilbert Blane, in his *Select Dissertations on Medical Science*, London, 1822; also in vol. vi. of *Transactions of the Medico-Chirurgical Society*.)

The historian of Anson's voyage, speaking of scurvy, says, 'the cure seems impossible by any remedy or by any management that can be employed.' In the present day, instead of the remedy being unknown, it is, happily, the disease:

a fact which suggests the most important subject for contemplation, and justifies the reflections and language of Sir Gilbert Blane: 'does it not afford a cheering and consolatory prospect, "amidst the thousand shocks that flesh is heir to," that there may be still in store for us, in the boundless progression and endless combinations of knowledge, other hidden means of advancing human happiness, of mitigating human misery, and of making accessions to the dominion of man over nature which have not yet been dreamt of in our philosophy.'

The other diseases to which the name of scurvy has been improperly given, and some of the remedies for which are termed antiscorbutics, have no connexion with sea-scurvy, or its remedies. These various affections of the skin are more or less connected with a scrofulous constitution, to which are owing the disordered functions of the digestion, whence these eruptions spring. Acidity in the stomach is a concomitant and characteristic symptom of these diseases, for the cure of which vegetable acids are unavailing, though the mineral acids, by their strengthening virtues, are often serviceable. These so-called scorbutic affections are of very frequent occurrence among persons subject to gravel and gout, which are, at the commencement, caused by acidity in the stomach: the appropriate means of cure for both complaints are alkalies (see ANTACIDS), the very opposite of the means useful in true scurvy.

The nostrums vended under the name of antiscorbutics, and intended for these cutaneous diseases, though varying in their composition, mostly contain, as their active principle, some preparation of mercury, often a very poisonous one, which is always hurtful in sea-scurvy, and can only be serviceable in particular cases of the other kinds. Its use requires the greatest caution, directed by the utmost skill; the employment of such articles should, therefore, be carefully avoided.

ANTISEPTICS, from *avri* against, and *σῆμα* to putrefy, the means of preventing those changes in organized matter which are comprehended under the term putrefaction. All organized bodies consist of different materials, which are designated their *proximate principles*, and these again are formed by the union or combination of certain *ultimate principles*. An organized body, therefore, is always a compound one, and the tendency of its original or natural proximate principles to form others, and, at last, to be resolved into the ultimate elements of which they are formed, is the occasion of putrefaction, which takes place in all bodies, sooner or later, according to the circumstances in which they are placed. To give an example of each: flour, prepared from what was once a living and organized body, called a seed, contains two proximate principles, gluten (bird-lime) and starch: each of these is resolvable into definite combinations of what are termed simple or *elementary* bodies, of the same nature as the constituents of inert or inorganic matter; the most common of these are *oxygen*, *hydrogen*, *carbon*, and *nitrogen*. The first or proximate principles are only met with in organized bodies; the latter equally in organized and inorganic matter. Oxygen, for instance, forms a portion of the air which we breathe, and also of water; hydrogen forms a portion, or is an element, of water; nitrogen is found in the atmospheric air; and carbon exists in the diamond, in the charcoal obtained from wood, or from animal matter.

All organized bodies spring from parents similar to themselves, possessed of, or endowed with, a vital principle. Every such body possesses the power of assimilating to itself matter introduced from without, whether inorganic, as table-salt, or organized matter, as dead animal and vegetable substances, in the case of man and some other animals, or merely inorganic matter, as in the case of vegetables. After being received into the interior of the body, these matters undergo changes previous to being distributed to that part of the frame destined for the reception of the different proximate principle which are formed out of them by the vital processes of digestion and assimilation. When deposited in the part intended for them, they would speedily enter into fresh combinations, were not their tendency to do so controlled by the agency of the living principle, which counteracts the usual chemical affinities of the constituent or elementary principles. When this principle is weak, or does not act with sufficient energy, either through the whole frame or in any particular part of it, the elementary principles manifest a disposition to exert their ordinary affinities, which would lead to the decompo-

sition of a part or the whole. Partial decomposition occurs when a limb or other part of the body has been the seat of such violent inflammatory action that its structure is changed, and its vitality destroyed, so that it *sloughs*, as it is technically called, that is, becomes dead: complete decomposition occurs when the vital principle quits the entire frame, *i. e.* when death of the whole body takes place, and putrefaction begins. But the presence of the vital principle does not always hinder the commencement of putrefaction, as we see the tendency to it manifested in the worst kinds of fevers several days before dissolution: on this account they were termed *putrid* fevers, and were conceived to be owing to putrescency of the fluids, a doctrine common during the prevalence of the *humoral* pathology. But more correct views of fever have taught us that the changes in the fluids, both as respects their properties and chemical constitution, are consequent upon a change in the vital action of the system, resulting from the impression of a powerfully morbid agent on the nervous or circulatory systems. This impairs the vital force or energy of the frame, and lessens the power by which the chemical affinities were controlled; and hence the early tendency to putrefaction in persons affected with fevers of a typhoid type or character.

The complete departure of the vital principle is not sufficient to occasion the commencement or ensure the continuance of the processes of putrefaction: the concurrence of several other circumstances is necessary. These are air, heat, and moisture: if any one of these be wanting, decomposition will in general be prevented. If the air has an admixture of certain particles or principles, the tendency to putrefaction will be greatly increased; and, on the other hand, impregnating the air with certain other principles, greatly lessens the disposition to decomposition. These circumstances have so large a share in the production or prevention of disease and death, that a thorough understanding of them is of vast importance to the welfare of the community.

The atmospheric air, considered in reference to its chemical composition, is a mixture of nitrogen and oxygen gases, in fixed and uniform proportion, with carbonic acid gas in a small and variable proportion. But close to the surface of the earth, it receives an admixture of particles or principles of different kinds, by which it is contaminated, and rendered less fit for the support of animal and vegetable life. By the respiration of animals, particularly of warm-blooded animals, as man, a portion of the oxygen is withdrawn, and a corresponding portion of carbonic acid gas is substituted in its place. By the respiration of plants, the carbonic acid gas is withdrawn, and an equivalent portion of oxygen substituted. By the mutual action of the members of the animal and vegetable kingdoms, the balance of the constituent elements of the atmosphere is maintained. But by a preponderance of the members of either of these kingdoms, an excess of the one principle and a deficiency of the other will be occasioned. Hence, where there is a large assemblage of men, the air is less fit for respiration, as happens in *close* apartments: the most melancholy example of this is to be found in the narrative of the Black Hole at Calcutta; of one hundred and forty-six persons confined in this dreadful place, *one hundred and twenty-three* perished during one night. Trees crowded together in plantations suffer more from deficiency of carbonic acid and oxygen, both of which are required for respiration, than from deficient nutriment by the roots—a fact of which proprietors and managers of timber-plantations are either not aware, or at least they neglect the practice to which it should lead. It may be remarked by every one that on the coast, where animal life acquires an accession of strength from the purity of the air, which abounds in oxygen, vegetable life languishes from the deficiency of carbonic acid. In addition to these sources of deterioration, the air is contaminated by various other means, some occasional and limited in their operation, others more constant and extended in their influence. A brief review of these will here be proper; but, before proceeding to enumerate them, it will afford conclusive evidence of their importance to adduce one example of the influence of even a slight admixture of a deleterious principle with the ordinary constituents of the air. 'This gas (hydro-chloric acid, or muriatic acid gas) must therefore be very injurious to vegetable life, since so small a quantity as a fifth of an inch, though diluted with 10,000 parts of air, destroyed the whole vegetation of a plant of considerable size in less than two days.

Nay, we afterwards found that a *tenth part of a cubic inch* in 20,000 volumes of air had nearly the same effects.' Drs. Turner and Christison, in *Brewster's Journal*, vol. viii. p. 145.

These are principles with the chemical qualities of which we are well acquainted, and the sources of which we can easily ascertain, and often remove; but there exist others, of the nature and origin of which far less is known, though their effects are very conspicuous: such are the exhalations from decaying vegetable matter, termed marsh miasmata, or malaria, and the exhalations from the bodies of men and animals, when crowded together, or from that of men labouring under certain diseases, as fevers, called the matter of contagion, or from dead animal matter, in a state of putrefaction, termed putrid effluvia. These are the fertile sources of fevers, whatever their form, type, or appellation; and though it is commonly thought that the fevers from vegetable matter are always of an intermittent or remittent character, yet they often assume the continued form (see *AGUE*); while the effluvia from animal matter mostly give rise to fevers of a continued and typhoid character.

What the precise nature of this deleterious principle is cannot be stated, but whatever it be, when received in sufficient quantity into the human system, it seems to act as a ferment or yeast, and produces a series of changes, the ultimate object of which is to reduce the body attacked to a state of putrefaction. We have no test of its presence beyond its effects, but we know the sources whence it springs, and the circumstances which favour its concentration, and occasion the human frame to become more susceptible of its influence. It is only by removing or lessening these that we can escape this insidious foe, and the success which has attended the enlightened measures proposed by physicians and chemists should lead to their extended application.

Long-continued calms, in which there is a stagnation of the air, and during which fresh and purer particles of the atmospheric principles do not descend from the higher regions to replace the heated and contaminated air near the surface of the earth, conduce much to the concentration and virulence of these agents. For several weeks before the plague broke out in London, in 1665, there was an uninterrupted calm, so that there was not even sufficient motion in the air to turn a vane. And at the season in which the last plague visited Vienna there had been no wind for three months. To produce agitation in the air, fires were formerly lighted, and pieces of artillery discharged, means altogether inefficient to cause a considerable commotion in the atmosphere at large, though a fire is extremely serviceable in renewing the air of apartments in houses: the only means adequate to this end are beyond our control, though they frequently take place at the moments of the utmost need; these are storms and hurricanes, which, however desolating in their immediate effects, are instruments of great, though less obvious, good. After the hurricane which proved so destructive to the inhabitants of the West Indies in 1780, less disease occurred than had been known before; even those who laboured under sickness at the time were benefited by it; fever, diarrhoea, and dysenteries, but, above all, disorders affecting the lungs, were cured. Cases of intermittent fever were observed to be cured by an earthquake at Caracas in March, 1812. (See Brande's *Quarterly Journal of Science* for 1817, vol. ii. p. 401.) After the excitation of a storm, plants give out more oxygen, which accounts for the delightful and life-giving freshness of the air, of which every one is sensible, who walks out into the fields immediately afterwards.

We may imitate nature, and employ ventilation on a small scale, but with the best effects, in our dwelling-places, hospitals, and sick-rooms. The evils of neglecting this salutary measure contrast strikingly with the beneficial consequences of attending to it. It is remarked by Dr. Macculloch, in his *Account of the Hebrides*, that while the inhabitants had no shelter but huts of the most simple construction, which afforded free passage for currents of air, they were not subject to fevers; but when, through the good intentions of the proprietors, such habitations were provided as seemed more comfortable and commodious, but which afforded recesses for stagnating air and impurities, which they had not the means, or had not a sufficient love of cleanliness, to remove, febrile infection was generated. The mortal fevers which have occurred from crowding human beings together in small ill-ventilated apartments are numerous. They were termed jail and hos-

pital-fevers, from their infesting these places: the survivors of the night in the Black Hole of Calcutta were, almost without a single exception, attacked by fever; and the unhappy victims of the mercenary actors in the slave-trade were often released from suffering by the fevers which resulted from crowding so many into a confined space. To avert such calamitous diseases, we must have recourse to measures which will lessen or remove their causes; such as dispersion of the inhabitants or patients over a larger space; enforcing cleanliness of the apartments and of their persons, and freely ventilating every room. Formerly, in the hospital at Leeds, no patient suffering from compound fracture or other severe accident survived, till the ventilation of the wards was improved. One of the most convincing proofs of the different influence of foul and pure air is to be found in the *Report of the Lying-in Hospital of Dublin*. In the space of four years, ending in 1784, in a badly-ventilated house, there died 2944 children out of 7650. But after freer ventilation, the deaths in the same period of time, and in a like number of children, amounted only to 279. Attention to this point will prove a protection from numerous causes of disease. The annual mortality of Manchester in 1757 was 1 in 25, and in 1770, 1 in 28; but in 1811 it was 1 in 74, a change mainly attributable to the improvements in ventilation effected by Drs. Percival and Ferriar.

Stagnant water, and the mud which remains after it has evaporated, marshes and places occasionally overflowed, emit exhalations not less noxious than those from decaying animal matter, or the bodies of human beings. These are the more powerful in proportion to the heat; hence, in tropical and warm countries, they give rise to the yellow-fever and the jungle-fever, which are rapid in their course, and generally fatal in their close: in colder countries they produce continued remittent and intermittent fevers. The exhalations are always less hurtful in proportion to the activity of the vegetation. The inhabitants of that part of the town of Batavia which is nearest the mud and slime left by the tide suffer more from fevers than those who dwell next the marshes, unhealthy as these are. In the marshes of Anké, a great number of different kinds of grasses, rushes, &c., grow, and the spaces between these plants are covered with large quantities of the *Pistia stratiotes*, the leaves of which float on the surface of the water, and absorb a great quantity of the noxious vapours as fast as they are exhaled, and change them, by the aid of the sun's rays, into respirable air. This change is effected by the pistia more than by any other plant; for it is known from experiments to be so powerful a preventive of decomposition of stagnant water, that if fishes be put into a small quantity of water, in which they would otherwise perish in the course of a few days, they may be preserved alive for a long time by covering its surface with these singular plants. The utility of a piece of moss introduced into the vase where gold fishes are kept is well known; and the *lemna* or duckweed, and other plants which cover the surface of ponds in summer, render a similar service to the air here, which the pistia does to that around Batavia. Where marshes cannot be drained, the planting them with marsh and aquatic plants, and such trees as alders and poplars, is the best mode of mitigating the evils which result from them. The beneficial effects of draining and forming under-ground sewers are shown in the perfect immunity which London enjoys from ague as an epidemic, contrasted with former times. Dr. Caius, the most eminent physician in England at that period, states, that the mortality of London from ague in 1558 was such, that the living could hardly bury the dead.

When these natural means of preventing animal and vegetable exhalations cannot be employed, we must have recourse to artificial means of disarming them of their potency. Of the measures formerly resorted to for this purpose, some were useless, while others were hurtful to the sick, and could not be practised without the removal of the patients, which can rarely be accomplished. All of them, in point of efficacy and facility of application, fall short of two agents, which bid fair to render every other superfluous: these are the chlorides of soda and of lime. In these preparations chlorine is combined with the bases in such a way as to be susceptible of decomposition, and is evolved with more or less rapidity according to the ingredients or impurities it meets with in the air. The most common of these impurities is carbonic acid gas, which is produced both by the respiration of living animals, and by the decomposition of

their bodies when dead. Another product of putrid animal matter is ammoniacal gas, which generally unites with the carbonic acid, and forms carbonate of ammonia, the presence of which may be recognized by the pungency of the air impregnated with it, which affects both the eyes and the organ of smell. Now it is interesting to remark, that carbonic acid gas has the greatest tendency to unite with the soda or the lime, and to liberate the chlorine. Again, chlorine decomposes ammoniacal gas by abstracting the hydrogen from the nitrogen, and forming hydro-chloric or muriatic acid. One example of its beneficial action will prove its utility. Air was passed through blood, which had been left to putrefy for eight days; being then passed through a solution of the chloride of lime, carbonate of lime was deposited, and the air was rendered inodorous and completely purified. These agents can only be productive of benefit within a limited range of atmosphere, yet they may be employed successfully to purify the air of hospitals, sick-rooms, &c.

Quick-lime, or charcoal recently prepared, has been employed to absorb fetid and noxious exhalations, and though inferior to the chlorides, may be used in some cases, such as when the patient cannot bear the smell either of the chloride of soda or of lime. When the matter of contagion is supposed to be attached to woollen or cotton clothes, we may expose these to a high temperature, 212° of Fahrenheit, for some hours, by which it will be dissipated.

An equally important means of warding off the effects of exposure to a contagious atmosphere, is to put the body in a posture of defence by strengthening it, and regulating the general health. Increasing the vital force of the system renders it less susceptible of being acted upon by impure air; hence nourishing food and tonic medicines may be regarded as indirectly antiseptics. It is a wise precaution not to visit the sick without previously taking food. But useful as a supply of proper nourishment is, still it is of inferior efficacy, as a protective means, compared with ventilation and cleanliness, as is demonstrated by the instructive fact, that in Great Britain, we were 200 years later in getting rid of pestilence than of famine. Most of the medicines which were formerly termed antiseptics are either tonics or refrigerants: of which cinchona bark may serve as an example of the first class, and the mineral and vegetable acids as dilute sulphuric acid, and tartaric acid or citric acid of the second. Tonic antiseptics cannot be employed with propriety or safety at the *beginning* of fevers or inflammatory complaints, but in many diseases a period arrives when they may be usefully administered. The period when their employment becomes safe requires the nicest discrimination on the part of the medical attendant; and too numerous are the instances where their premature employment has rekindled the disease which might otherwise speedily have subsided. We are, however, justified in having recourse to them at an earlier period in those diseases which we know to have a great tendency to lead rapidly to the death of some part; such as in the malignant or putrid sore-throat of scarlet fever; or in continued fever of a very typhoid character.

The refrigerating antiseptics may be beneficially used from a very early period of inflammatory diseases, especially of the young and robust: in such diseases as scurvy (i.e. sea-scurvy) they surpass all other remedies.

As the operations of nature in regard to organized matter seem to consist in reducing to their elementary state each individual, or part, when it ceases to live, and in reconstructing others, it forms an interesting and important subject of investigation to inquire in what way the former of these may be prevented, when it is desirable to preserve the whole of a part of organized matter from putrefaction; by what means can the tendency to putrefaction be so modified, that the result of it, though leading to the formation of a substance having a very different character, shall yet be of a kind which may be preserved for a longer period, than the original substance; and how the process of putrefaction may be rendered a useful, instead of a noxious operation. The first two questions concern the preservation of food, so that the produce of a period of plenty may be stored up as a provision for a time of scarcity, and the superabundant productions of one country may be transmitted in a sound and wholesome state to a distant land. It also concerns the provisioning of our ships, so as to ensure the health of the crews, as far as depends upon a proper supply of animal and vegetable diet. The last question relates to the beneficial application of putrefying materials to the soil as manures.

All organized substances do not putrefy with equal rapidity, nor under all circumstances. Decomposition goes on fastest in substances which contain nitrogen; most slowly in substances which contain carbon: hence animal matters putrefy quickly; vegetable, especially of a woody texture, gradually: the decomposition of the former is characterized by an unpleasant odour, and the formation of ammonia; that of the latter is rarely unpleasant, except it be of vegetables which contain nitrogen, such as cabbages and fungi. The conditions necessary for the process of putrefaction to take place are, the presence of air, of a certain temperature, and moisture. If any one of these be excluded, the process is prevented. The moisture may either be external, or it may be the fluids of the body itself. The bulk of the animal frame is made up of fluids the preponderance of which over the solids is strikingly illustrated by an entire, but perfectly dry, natural mummy of a full-grown native of the island of Teneriffe; though all the solid parts of it are preserved, it does not exceed seven pounds and a half in weight. The fluids must either be dissipated by heat, abstracted from the body by some chemical process, or rendered solid by a very low temperature, if we wish to preserve any animal substance in the state most near that of its natural constitution. For the sake of clearness, we shall here speak of the modes of preserving food under two heads, the natural and the artificial.

The former modes comprehend those which effect this end by abstracting or excluding one or more of the chief agents,—heat, moisture, and air,—and furnishes the answer to our first question: the latter comprehend those methods of preparation or mixture which may be considered to be the answer to the second question.

1st. Abstraction of heat. The presence of heat is essential to the exertion of those chemical affinities which take place during, or constitute the process of, decomposition; abstracting it, therefore, checks or suspends them; most articles of food keep better in cold than in warm weather. When the heat has been so completely abstracted that the juices are frozen, *i.e.*, become solid, the preservation of the substance is more effectually accomplished. Indeed they may thus be preserved for a time almost beyond belief. In the year 1779, on the shores of the Frozen Ocean, near the mouth of the river Lena, an animal of immense size was discovered imbedded in ice, which, as it melted, gradually disclosed him to view. His hair, skin, and flesh were in so good a state of preservation, that dogs and many wild animals preyed upon it. (Some of the hair may be seen in the museum of the Royal College of Surgeons, Lincoln's-inn-fields.) In the opinion of Cuvier, this animal differs from every known species of elephant, and is, therefore, considered by him as *antediluvian*, and to have been preserved from the remote period of the deluge in the mass of ice which enveloped him.

On this principle the Russians preserve their poultry, which they kill in October, and pack in tubs with layers of snow between. The markets of St. Petersburg are supplied with veal brought from a great distance in this state, as well as with whole hogs, sheep, and fish. The Canadians preserve their provisions in the same way. Almost the only instance in which we adopt this practice is in sending fish from Scotland to London; but it might be employed for the preservation of many other articles, eggs for example.

A precaution is necessary in thawing them; for this end, they should always be put into cold water first. Indeed, in the case of persons lost in the snow, recovery is much more likely to be brought about by plunging the individual into cold water, than by placing him in a warm bed.

This method of preserving food is not applicable to vegetables, but when these are frozen they should also be first put into cold water.

2nd. The abstraction of moisture by heat is employed in drying fish and other animal substances, as beef, bacon, &c., though in these the rapid tendency to putrefaction makes the employment of a certain quantity of salt, &c., along with desiccation necessary, unless the process be carried on with great rapidity, which may be effected by a high temperature and a free circulation of air. Hence in many places, where turf or peat is burnt, hams are hung within the wide kitchen-chimney; but, by this means, the juices are dissipated, and, consequently, the flavour, as well as nutritious property, of the meat is lessened, and its indigestibility is increased. This method is better suited for the preservation

of vegetable substances, such as grain, hay, &c. It is by this means that botanists preserve plants to form a hortus siccus, or herbarium, and many plants are preserved for medical use. But in the case of these last, a high temperature should never be applied, as it dissipates their active principles.

3rd. The exclusion of sources of oxygen-gas constitutes another means of effecting the end in view; and as the atmospheric air is the most common, as well as universal, source of oxygen, we shall limit our remarks to the means of excluding it. The influence of this is very great. Réaumur varnished some eggs, and found that at the end of two years, they were yet capable of producing chickens; and Bomare mentions an instance where three eggs were inclosed within the walls of a church in the Milanese, and when found at the end of 300 years, they had not lost their flavour. On this principle butter is rubbed by careful housewives over their eggs; lime-water, however, is the best medium in which to place eggs for long keeping. But more valuable articles than eggs are preserved by this means; and in a condition nearly equal to their fresh state. We allude to the method of preserving animal food and vegetables, promulgated by M. Appert. This consists in boiling the articles (if meat, the bones must be first taken out) to nearly as great a degree as if intended for immediate consumption; they are then put into jars, or now generally into tin canisters, which must be completely filled with a broth or jelly prepared from portions of the same meat. The jars are then corked and covered with a luting formed of quicklime and cheese, or if canisters be used, these are carefully soldered down. After this, they are placed in a boiler of cold water, to which heat is then applied till the water boils, and the boiling of which is continued for an hour; the fire must then be instantly extinguished, and the water soon drawn off, but the boiler must not be uncovered, or the bottles taken out for one or two hours after.

By this method meat may be kept sound and well-flavoured for six years, or even longer, and sent to any part of the globe. (See Appert, *Art of Preserving Animal and Vegetable Substances*, London, 1811.)

The natural methods of preserving organized substances are few and simple: the artificial more numerous, as well as more complex. They consist either in causing such changes in the elementary constitution of a body as shall form a new and less destructible article, or by introducing some additional principle which shall hinder the exercise of the natural tendencies or affinities of the elements of the substance.

The first set of means constitute the various kinds of fermentation, of which this is not the place to treat, but with respect to which we may remark that the products of them are not only little disposed to undergo decomposition, but have also a powerful effect in preventing other substances from undergoing it; the most remarkable of these are acetic acid or vinegar, and alcohol. The mode of action of vinegar or pyroligneous acid in preventing the decomposition of animal and vegetable substances has not been determined, but alcohol is supposed to act by abstracting the elements of water. The formation of sugar, which is another product of fermentation, is a powerful means of preserving fruits, in which it is formed spontaneously, or to which it is afterwards added. Fruits are ripened by the conversion of the acid which they contain into sugar, and as this requires the aid of light and heat, fruits gathered in the afternoon are less acid than if gathered in the morning, and keep much better. The addition of sugar is practised in forming syrups, jellies, and preserves.

Those parts of plants which contain much carbon last the longest, whether dead or alive: many vegetable structures have been preserved entire, imbedded in charcoal, in the most ancient coal formations; and in bogs and mosses, trees are met with, having a perfect integrity of structure. Even in trees cut down and exposed to air and moisture, the bark, which contains most carbon, endures after the rest has perished. The seed also contains much carbon, and owing to this retains its vegetative power often for a hundred years or more. When seeds are sent from India to England, they are always wrapped in recently prepared charcoal. When stakes or piles of wood are to be driven into the beds of rivers or marshes, they are previously charred; and to preserve water sent to sea, the inner side of the cask is also charred. A more perfect mode of preserving water from becoming

putrid, is to saturate it with fresh lime, (and in this lime-water, eggs for use at sea may be kept :) when the water is needed, the addition of a few drops of sulphuric acid (oil of vitriol) will precipitate the lime, and leave the water pure and wholesome. But for this purpose it must be carefully closed against the admission of the air, otherwise the lime will be precipitated by abstracting carbonic acid from the air.

There are many substances which when added to animal matter prevent for a longer or shorter time their decomposition, such as salt-petre (nitrate of potass), and common salt (chloride of sodium), which last is supposed to act by abstracting the elements of water : certain it is that meat is rendered by salting much drier, harder, less easily digested, and consequently less nourishing. [See ANTISCORBUTICS.] Many aromatic substances have a similar power of preventing putrefaction for a time. They were extensively employed in embalming in antient as well as modern times, as the Egyptian mummies prove. Oils and resinous substances long resist putrefaction, and preserve other substances from it ; bitumen, naphtha, and empyreumatic oils, are examples of this. Russia leather, which is dressed with the empyreumatic oil of the birch, not only does not become mouldy, but also preserves the books which are bound with it. The process of decomposition is greatly hastened by the agency of fungi, such as those which cause mouldiness, and the more formidable destroyers which occasion the dry-rot. The fungi which cause mouldiness are generally prevented from developing themselves by the presence of some aromatic oil ; and the others which occasion the dry-rot in timber, may be prevented from developing themselves by the process invented by Mr. Kyan. This consists in combining the albumen of the wood with bi-chloride of mercury (corrosive sublimate), which it converts into the proto-chloride, in the same way that animal albumen combines with, and converts into the proto-chloride, the same compound (see ALBUMEN); the wood is thus rendered insusceptible of the attacks of the fungi. Fungi often attack and destroy the cereal grains, particularly wheat: the worst of these, viz., the *uredo fœtida*, (pepper-brand,) may be prevented from farther developing itself by steeping the seeds for twelve hours in lime-water. (See Paper by Mr. Bauer, in *Penny Magazine*, No. 64.)

Insects are frequent agents of nature in forwarding the processes of decomposition. Some penetrate growing trees, and either injure them by opening a passage to air and moisture, or by depositing their eggs, the larvæ from which feed upon the juices and organs of the trees. Such is the destructive power of some insects in this latter way, that some years ago a million and a half of pine trees, in the Hartz mountains, perished from the ravages of the *bostrichus typographus*, 80,000 larvæ of which were found in one tree. About fourteen years ago, the elm-trees in St. James's Park, and the environs of London, suffered greatly from a small insect called the *hylesinus destructor*. The only means yet known of stopping these, is the expedient suggested by Mr. M'Leay, of cutting down the trees and burning them, when the eggs have been deposited, before they turn to larvæ or winged insects.

The collections of entomologists and botanists suffer much from the depredations of insects. Those which infest collections of insects may be driven away by placing camphor in the cases, or by introducing a solution of bi-chloride of mercury into the blood-vessels of larger animals previous to stuffing them. Dried plants, for botanical specimens, may be preserved from the attacks of the *pinus fur*, by applying to them, when perfectly dry, a solution of bi-chloride of mercury, of the strength of two drachms to a pint of rectified spirit of wine, to which a little camphor has been added. It must be applied to the whole specimen by means of a camel-hair pencil.

The last question proposed to be answered, was how to render the process of putrefaction of bodies useful, instead of pernicious. The obvious answer to this is, to bury them under the surface of the earth. Animal bodies should be buried sooner than most vegetable substances ; but cruciferous plants, such as cabbages, when exposed to the air, are as pernicious as any, and should be buried ; some years ago a severe fever originated at Cambridge, owing to a quantity of cabbages having been thrown over a garden-wall. Such matters should always be buried as manure. 'In this case the food of plants is prepared where it can be used ; and that which would offend the senses, and injure the

health, if exposed, is converted by gradual processes into forms of beauty and usefulness ; the fetid gas is rendered a constituent of the aroma of the flower, and what might be poison, becomes nourishment to men and animals.' (See *Davy's Lectures on Agricultural Chemistry*.)

ANTISPASMODICS, from *ἀντι*, against, and *σπασμός*, spasm, the means of removing spasm. The state called spasm, or cramp, occurs only in muscular structures, and consists in an irregular, and often excessive, action of particular fibres of a muscle, of an entire muscle, or of several muscles. The muscles of an animal of the higher degrees of organization, such as man, are divided into two classes, the one set comprising those which are concerned in carrying on the functions most essential to life, viz. the circulation, respiration, and digestion, which act independently of the will, and are therefore called *involuntary* muscles ; the other, which are organs of motion, and subject, in a certain degree, to the control of the will, are termed *voluntary* muscles. Each set act in consequence of the application to them of some stimulus ; and their action is only uniform or natural when their appropriate stimuli are applied. The heart, for example, contracts from the stimulus of the blood ; and the intestines are so constructed as to have proper motions excited in them by the food which we take, and the secretions which are mixed with it ; which actions, in the healthy state, go on, not only without our willing it, but also without our consciousness. The stimulus to the other set is either a sensation felt in the part and communicated to the chief nervous centres, viz. the spinal chord or brain, or a spontaneous effort of volition proceeding from the brain, and originating in some thought, and connected with some purpose or design, to be executed by the muscles thrown into action. Of the motion of such muscles we are always more or less conscious, and when the system is in its perfect or usual state of health, we can repeat their action for a considerable length of time, and regulate its degree by repeated and distinct efforts of the will ; as when a man walks, and quickens or slackens his pace according to his inclination. But a variety of circumstances influence the action both of voluntary and involuntary muscles, and render it irregular : when influenced by any of these, the action of the involuntary muscles becomes sensible and painful, and the voluntary muscles cease to be under the control of the will, and act not only without its stimulus, but often against its consent. These disordered actions would appear to be owing to some improper stimulus, instead of the appropriate one, being applied to the organ or part affected. Venous blood, circulating in the arteries, is productive of great disturbance ; and if much of it be conveyed to the brain, it will act as a poison to that organ, for which arterial blood is the natural stimulus as well as source of nourishment. In like manner there are bodies which, though perfectly mild, such as alimentary substances of difficult digestion, yet excite more violent commotions of the stomach than other substances which are of a very acrimonious nature. Undigested food, or unhealthy secretions, in the intestines, excite more disturbance and spasmodic contractions (*i.e.* choleric, in different degrees of severity) than foreign substances, which we might expect to prove very hurtful ; such, for instance, as the poison of the viper, which is perfectly innocent when received into the stomach.

Both voluntary and involuntary muscles, and the organs of secretion, are very much influenced by emotions of the mind. Under the influence of hope or joy the heart beats vigorously, while under the depressing passions its action is slow and laborious, and accompanied with such oppression as to have given origin to the phrase, 'a heavy heart.' Fear excites to irregular contraction and relaxation many of the voluntary muscles, whence comes trembling ; and produces relaxation of certain muscles, called sphincters, which are usually contracted ; it also augments several of the secretions. Grief, when not excessive, increases the secretion of the lachrymal gland, producing a flow of tears ; if extreme, it hinders secretion, and forms the state truly characterized by our great poet—

'A misery too deep for tears.'

Anger often causes the bile to be secreted in greater quantity, to be altered in its quality, and often absorbed in the blood, thus producing jaundice. The state of mind which may be termed vexation often lessens the secretion of bile, and augments that of the kidneys ; and every attack of hysteria terminates in a profuse flow of limpid urine, which is a state of the usual admixture of bile.

These mental emotions, either directly, or indirectly through the altered and unhealthy secretions, occasion in many persons spasmodic contractions of some muscular organs, which are so violent as to produce alarming and often fatal diseases. Of this, *ANGINA PECTORIS* furnishes an example; and so powerful are the effects of excessive joy in some instances, that the heart *bursting* is not a mere figure of speech, and of grief in other instances, that the heart *breaking* is not a metaphor, but a reality. Many spasmodic actions, such as the cough of whooping-cough, are kept up by habit; others, such as the strange gesticulations of St. Vitus's Dance, are acquired from imitation, as stuttering or stammering is occasionally; and both may become a habit, difficult, if not impossible, to lay aside.

What is termed sympathy is even more powerful than imitation, which implies a voluntary adoption of the peculiarities of others: scarcely any persons in a company can avoid yawning if one sets the example. Now, yawning is an involuntary spasm of the muscles of the jaw, which is thus propagated through a large assemblage of persons; so hysterical and even epileptic spasms are communicated from one to another, often to a frightful extent, if an individual subject to these complaints suffer an attack in theatres, churches, or private apartments. Such an occurrence is sometimes merely the result of affectation, but more frequently it is the consequence of an irresistible impulse. No one was ever seized with tetanus from witnessing the spasms of a person affected with that excruciating disease; a circumstance which can only be accounted for by observing that in it the mind is in no degree implicated, the mental faculties remaining clear and undisturbed to its termination: and there is reason to believe that in this complaint some inflammation or peculiar state of irritation exists about the origin of the nerves, which no one can induce at will, and which neither primarily nor secondarily happens in the others, which are more strictly nervous affections, *i. e.* merely disorders of the functions of nerves without alteration of structure. The development of tetanus is slow, often not showing any sign of its intended attack till some days after the cause of it began to operate on the system. The others are mostly instantaneous, unexpected, and rapid in all their stages. The impression they make on the by-standers is increased by the surprise felt at their unlooked-for occurrence, often without any obvious or sufficient cause. The more sensitive of those around are therefore most apt to fall into a similar state or train of actions. Of the persons so affected, the greater number will be found to be females. What causes render them more subject than others to such attacks? Females, from the larger size of their nerves, are more *mobile*, as it is technically expressed, *i. e.* more easily operated upon by slight causes than others, and their habits of life and education have often a great tendency to increase this sensibility. Whatever diminishes the strength, whether of mind or body, markedly predisposes to such complaints. The female children of the higher and middle ranks, feeble by birth, are rendered more so by the improper modes of education, physical as well as mental, to which they are subjected. After emancipation from the nursery and school-room, their minds and bodies are further enervated by an injudicious course of reading, and an early devotion to the prevailing habits and usages of fashionable life. Such pursuits preclude the possibility of applying themselves to solid studies, or the acquisition of any knowledge of the human system, and of the necessity of maintaining a regular action of every organ and performance of every function.

By a neglect of one of the most important of the natural functions, *viz.* regular and complete evacuation of the bowels, the tone of the intestines is lessened. Now, when the muscular fibres of any particular part are under a state of more or less tension than the rest of the system, this is communicated by sympathy to every other part of the body. This is particularly observable in the blood vessels and intestines, both of which are muscular tubes; for a relaxation in any part of these will produce a like affection in every other part of the system. And as irritability and sensibility are very much affected by the degree of tension, a want of it in the vessels constitutes what is called a *nervous habit*, such as is most commonly met with in the female sex, and weak, effeminate members of the other sex: such persons will generally be found to be of a costive habit. The peculiarities of the female system have a large share in increasing the disposition to be powerfully acted upon, at times, by trifling

causes. Exhausting discharges, to which they are very subject, greatly augment the irritability; and all diseases of a very weakening nature will produce a similar effect in the individuals of either sex: during convalescence from these, a disposition to irregular distribution of the blood exists, and a slight excess sent to one part, or a deficient supply of it to another, will cause disorder of the functions of that part. If it be any portion of the nervous structure which is subjected to these errors, spasmodic action is almost surely the consequence. Nothing is more clear or open to proof, than that convulsive motions result from two opposite conditions of the circulatory system, as relates to the quantity of blood, or rapidity of its flow. An animal while bleeding to death suffers violent convulsions, and an excess of blood sent to the head, or its stagnation in the vessels, will produce the same effect; which, indeed, often follows mechanical pressure of the brain, from a portion of depressed bone of the skull, or from effusion of the serum of the blood, in inflammation of the membranes of the brain. The fullness and distension of the vessels of the brain which precedes apoplexy often occasion vomiting, which is a convulsive action of the stomach and some other muscles, and is a warning sign, often unhappily neglected, of the approach of this disease. The more extensive and violent convulsions of epilepsy are, in all probability, the result of a temporarily deranged state of the circulation within the brain, as the loss of consciousness at the time of the attack, the progressive impairment of the intellectual powers, and the usual termination of the disease in apoplexy, palsy, fatuity, and death, attest.

The nature of the causes of the different diseases of which spasm forms, in general, a feature, the complication of these with other diseases or morbid states, and the manner in which each terminates, should all be taken into consideration, if we hope to make a beneficial selection of a remedial agent from among the number of antispasmodic medicines. But such a judicious preliminary measure is rarely adopted; and these articles are often administered in a manner truly empirical, by many professional as well as all unprofessional persons. A brief review of the diseases in which antispasmodic medicines are employed, and which agree only in having spasm for one of their symptoms, while they often differ widely in their causes, nature, and termination, will convince every one how needful is a knowledge of these points to guide us in the choice of the means of cure. The following is not given as a perfect classification or even as an approximation to one, but is merely intended to show the diversified nature of spasmodic diseases, and to furnish an argument for caution in the management of them. The treatment must vary greatly, according as the particular disease is attended with inflammation or not, or according as there is a risk of its occurring, either in the natural progress of the disease, or in consequence of the employment of improper means of treatment. The selection of remedies must be determined also according to the stage of the complaint, and according to the mode in which it is connected with the state of the mental faculties, or its tendency to involve these in the train of morbid actions, if it be not cured before such a calamitous termination take place. Keeping these points in mind, we may arrange spasmodic diseases, in some degree, as follows.

Unattended with inflammation, primarily, or disturbance of the mental faculties:

Simple Cramp. Cholice.—These generally proceed from some undigested substance, or hardened fæces, irritating the bowels: but in the latter disease inflammation is apt to come on; and in the worst forms of cholice, called *ileus*, or *iliac-passion*, and painter's cholice, it seldom fails to supervene, and then becomes the chief source of danger, as well as most important object of the treatment.

Diarrhoea, or simple looseness, and Cholera.—In these the cramps or spasms are never the first signs, but seem to result from the exhaustion occasioned by the profuse liquid discharges. Inflammation may occur during, or from, diarrhoea, and fever is the most common consequence of cholera, *i. e.* of epidemic cholera; the occurrence of which in either case must lead to a modification or alteration of the plan of treatment.

Angina Pectoris. Asthma.—Affecting the organs of respiration and circulation.

Attended with inflammation, primarily, but causing no disturbance of the mental faculties:

Dysentery.—Affecting the organs of digestion.

Croup, Hooping-cough.—Affecting the organs of respiration.

Unattended with inflammation to an appreciable degree, perhaps in no degree

Hysteria.—Not affecting the mental faculties, except the volition.

Chorea. St. Vitus's Dance.—Unattended with loss of consciousness; and—

Epilepsy.—Attended with loss of consciousness.

These two diseases sooner or later affect the mental faculties, and have a tendency to a common termination, viz., fatuity, unless they subside spontaneously, or are cured by medical treatment. Chorea generally originates from, or is connected with, accumulations of the bowels, and epilepsy frequently from a similar irritation of these parts, such as worms, but its causes are numerous, and its cure, in most cases, difficult.

Spasmodic diseases, of an obscure nature, chiefly affecting the organs of respiration :

Tetanus and Lock-jaw. Hydrophobia.—These may at some period become attended with inflammation, or rather fever; but this appears to be the result of the constant suffering, and is seldom the direct cause of death, which seems to be the consequence of that depression of the heart's action which long-continued pain or unpleasant sensations produce.

Diseases in which inflammation is the primary affection, spasm the secondary :

Inflammation of the Brain—acute, Phrenitis.

Acute or chronic, *Hydrocephalus*, i. e. *Water in the brain*, occurring mostly in children of a scrofulous habit.

Fever.

The treatment of these diseases is as diversified as their causes; and, to be successful, requires a degree of judgment and knowledge which few possess. To comprehend the nature of those spasmodic diseases which are unaccompanied by inflammation, and for which antispasmodic medicines are chiefly employed, we must be made aware that, in the human system, there are two distinct sets of nerves, having different origins, and fulfilling separate functions; the one set are called nerves of sensation, the other nerves of motion. The former receive impressions, and convey the sensations from all parts of the body to the brain; the latter execute the dictates of the brain by conveying an impulse from it to the organs of motion. The organs of motion—i. e. the muscles—are so adjusted, and in the healthy state so equally supplied with nervous energy, as precisely to balance or antagonize each other (see *ANTAGONIST MUSCLE*); and one muscle, or set of muscles, can only overbalance another, or several muscles, when it receives an additional supply of nervous energy, from an effort of volition. Thus the hand is opened and shut at will: when opened, the extensor muscles overpower the flexor muscles; when shut, the flexor muscles overpower the extensors.

In diseased conditions of the nervous system, this fine balance is lost from various causes: the nerves of sensation may become preternaturally sensitive; the nerves of motion may become paralysed; the power of voluntary motion may be perverted in various ways and degrees; the flexor muscles, independent of volition, may overpower the extensors, or the extensors the flexors. When affected with tetanic spasm, the extensor muscles of the back of a delicate girl could not be replaced in the natural state of equilibrium by any effort of the will, nor by a weight of eight hundred pounds: and under the influence of hysterical or epileptic excitement, a delicate person cannot be controlled by three or four robust men. The action of the muscles is so violent, that the fibres are sometimes torn across, or even the bones fractured.

Some of these spasmodic diseases give, at times, an intimation of their approach, generally by a peculiar sensation being experienced in some part of the body—often the thumb in epilepsy, or between the stomach and throat in hysteria; the spasmodic actions not commencing till these sensations have reached the brain. At other times no warning sensation is felt; yet often, on careful examination, some tender spot will be discovered, of which the patient was not in the least degree previously aware. In hysteria this tenderness is generally felt at some point along the course of the spine or back-bone; and in no case of spasmodic disease should we ever omit a minute examination of this part. Should drawing the finger along the course of the spine, and making firm pressure as we proceed, not reveal its existence, a

sponge, dipped in water as hot as can be borne, will, in its progress along the spine, cause the patient to start when it reaches the tender spot. The discovery of this will often furnish a key to all the strange symptoms and spasmodic actions, as well as explain the capricious conduct, of the sufferer, which has alarmed the friends, and puzzled the medical attendant. When appropriate treatment is directed to this point, most of the troublesome symptoms abate, or cease altogether.

As most spasmodic diseases, especially if connected with affections of the mind, have a great tendency to recur and become habitual, it is of the utmost importance to stop them at an early period.

The remedies which have been found most efficacious in stopping or preventing these, are either such as make strong and new impressions on the organs of sense, and thereby diminish the effect of sensations already existing, or such as blunt the sensibility in general, and thereby diminish all effects of sensation: or else such as raise the whole of the system to a level with the part spasmodically excited, and so establish the equilibrium, from which forced state all muscles may simultaneously subside.

The fibres of each muscle act generally in concert: if a few act independently of the others, these are in a state of cramp. Particular sets of muscles act in concert, as all the flexors, or all the extensors: one or more of these acting independently of the rest cause spasm. Now we often relieve this by calling the others into action; and as volition simply is not equal to this, we use mechanical or medicinal means. Cramp of the limbs is often removed by pressing the toes or fingers against a resisting body, by which all the muscular fibres are brought to the same level. This example of a mechanical process is the only one worthy of mentioning, and is only applicable in slight cases, as cramp of the limbs is generally merely a symptom of some internal derangement of the bowels, of the spinal chord, or of the brain.

The medicinal means constitute the antispasmodic remedies, and are of different kinds. Very few articles are, strictly speaking, merely antispasmodics, i. e., used solely to allay spasm, and incapable of being employed for any other purpose. On the contrary, this is only a particular application of substances capable of serving other, and more general, ends. Consequently, many of the so-called antispasmodics belong to other classes of medicines, such as the stimulants, particularly diffusible stimulants, as alcohol (brandy,) sulphuric ether, camphor, &c., or to the narcotics, such as opium, belladonna, &c.; or to the tonics, such as metallic salts, viz., of iron, zinc, and silver; or vegetable bitters, as cinchona bark. The first set or stimulating antispasmodics act, apparently, by rousing the nervous energy of the system, and raising the neighbouring muscles to a level with the part in a state of spasmodic excitement. The second set act by rendering the nervous system torpid, and insensible to every sensation; in large doses producing complete insensibility, even to the extent of coma and death. These two are administered when an attack is threatened or actually begun; the tonics are administered while the patient is free from an attack, and act by strengthening the system, so as to render it less susceptible of being acted upon by slight causes, particularly the irritating cause, known, or supposed, to excite the paroxysm or fit. The substances which are more especially considered as antispasmodic are *volatile oils*, such as mint, lavender, &c. derived chiefly from the tribe of the labiatae; or *cajeput oil*, from myrtaceae; or dill, anise, fennel, &c., from the umbelliferae, from which tribe also are derived the foetid gums, as they are improperly termed, being gum-resins, such as assafoetida, galbanum, &c. These, with valerian and myrrh from the vegetable kingdom, and musk and castor from the animal kingdom, are the most valuable antispasmodics. All the volatile oils seem to act in the same way as the purely stimulating antispasmodics; while the foetid gum-resins act by substituting new and powerful sensations instead of the morbid ones, and must be administered generally when the attack is threatened or begun.

These kinds of antispasmodics differ in value, not only as relates to their mode of action, but to their safety. The stimulating antispasmodics are only admissible when a fit is threatened, or may have begun; and as they greatly excite the vascular system, i. e., quicken the circulation, if upon their being given once they fail to remove the spasm, they should not be repeated. This caution is more espe-

cially necessary in respect to brandy, which is too commonly resorted to on every threatening or attack of spasm, such as cholera. So many of these diseases being connected with, or disposed to end in, inflammation, the free use of brandy, or other stimulant, is decidedly injurious. The inflammation in croup, whooping-cough, and dysentery must first be removed by appropriate means, when the spasm will generally subside or disappear entirely: if it should remain, in whooping-cough, in a great measure from mere habit, antispasmodics may be used, but even then the narcotic antispasmodics, such as Prussic acid, paregoric, or nuxbana, are to be preferred. The propriety of employing belladonna extensively in this disease is very questionable. (See Golis on *Hydrocephalus*, translated by Dr. Gooch.) The external employment, in the form of embrocations, of the stimulating antispasmodics, is more allowable in cholera or whooping-cough; but here they act on a different principle, viz., that of counter-irritation. This is, in itself, a most valuable means of curing spasmodic diseases. An irritating application to the spine is of much service in whooping-cough: tartrate of antimony ointment or plaster (see ANTIMONY) applied to the tender spot, which we have said often exists in hysteria, and other similar diseases, will be productive of more good than all the antispasmodic medicines which can be tried. (See Teale on *Neuralgic Diseases*.) Stammering, or other difficulties of speech, might be materially diminished by repeated irritating applications, as blisters, tartrate of antimony ointment, &c., to the nape and sides of the neck. Severe hiccup, continuing for several days, and which resisted all internal remedies, has yielded to a blister applied along the side of the neck. Every physiologist will understand how this happens.

The means which may be employed to intercept the passage of the peculiar sensation to the brain are merely mechanical; for example, tying a string tightly round the thumb prevents the *aura epileptica*, in epilepsy, reaching the brain, and wards off the attack. A cupping-glass would answer as well if applied to any large spot whence the sensation arose.

Free scarification of the gums in children, when teething, is much more efficacious in allaying convulsive affections than internal medicines, except mild purgatives.

The medicines which may be administered while the patient is free from a fit, or in the intervals of the paroxysms, are much more likely to effect a cure than the others. These are tonics and purgatives. For the reasons already stated, purgatives are of primary importance, as they unload the bowels, improve the secretions, and impart vigour to the whole muscular system. Many cases of severe spasmodic disease have been cured by the use of purgatives only, and none can be cured without their free and daily use for some time. (See Hamilton on *Purgative Medicines*, sixth edition.) Aloetic purgatives are, in general, the best; but where, as in epilepsy, there is reason to suspect the existence of worms, oil of turpentine is to be preferred.

After purgatives have been administered for some time, should the disease not have yielded, metallic or vegetable tonics may be employed with great advantage, particularly in hysteria, chorea, epilepsy, and stammering. In hysteria, chorea, and stammering, the preparations of iron are in general best; in epilepsy, preparations of zinc, of copper, but above all of silver, are preferable: sulphate of quinine is also very serviceable.

For the cure of hydrophobia, or tetanus, nothing has yet been found to succeed. There is some reason to hope that, for tetanus, a powerful vegetable compound from South America, called the *woorali*, may be beneficial, if we may judge by its effects on animals affected with tetanic spasm. (See cases by Mr. Sewell, in *Morgan's Lecture on Tetanus*, Appendix, London, 1833.)

Several of the diseases of which we here speak being connected with mental emotions, and some of them originating from imitation or being kept up by habit, mental agency has sometimes been employed to effect a cure, and occasionally with success.

Upon a threatened attack of hysteria or epilepsy, powerfully attracting the mind to a different object than that which occupies the attention of the patient may ward off the fit. But this requires great judgment and discretion. Formerly the most disgusting means were resorted to, and the sufferers were made to swallow animals of a forbidding kind, or other equally repulsive measures were tried. These cannot be

too much reprobated; and we should bear in mind that chorea, or epilepsy, may be brought on by a sudden fright. The separation of a person subject to chorea, or hysterical and epileptic fits, from among others, is often necessary; and when we know that the spasmodic actions are the effects of imitation, the employment of fear may be justifiable; but in any other case it would be criminal to have recourse to it and thereby, perhaps, add a mental disorder to a bodily one, already sufficiently afflicting.

Our endeavours to lessen the tendency to nervous diseases will be most successfully directed to regulating the education, physical and moral, of children, especially of female children. This subject has been already treated of under the article *Αἰσ*, to which we refer, as well as to Number XXIII. of the *Foreign Quarterly Review*, Art. v. 'Hypochondriasis and Hysteria'; also to the excellent chapters on Spinal Irritation, Choreia, Hydrocephalus, and Convulsions, in Burns' *Principles of Midwifery*.

ANTI-STHENES, the pupil of Socrates, the master of Diogenes, and commonly reputed the founder of the Cynic school. The time of his birth, as well as that of his death, is uncertain; but he was the contemporary of Socrates, Plato, Aristotle, Xenophon, &c., and may be said in general terms to have flourished about 380 B.C. Diodorus Siculus mentions him as still alive in the third year of the 103rd Olympiad, corresponding to B.C. 366. (See Clinton's *Fasti Hellenici*, p. 107.) According to Diogenes Laertius, who has given a life of him in his sixth book, he was born at Athens, of which his father, named also Antisthenes, was a citizen. His mother was a native of Thrace, or, as Plutarch says, of Phrygia. He first attended the school of the Rhetorician Gorgias; but, leaving him after some time, he became a follower, and eventually one of the most distinguished disciples, of Socrates. He afterwards established a school of his own, in a place a short distance from the city, called Cynosarges. Whatever may be the origin of the word Cynosarges, it is not impossible that this term may, as some writers assert, have given birth to the appellation Cynics, by which the followers of Antisthenes came to be known. We prefer, however, the more obvious derivation which deduces the epithet directly from *κυν*, a dog, and regards it as simply expressive of the popular notion respecting the character of the sect of philosophers so designated. The opinions of the Cynics will be discussed under that word. We may here merely remark, that it is certainly a mistake to rank them as ascetics. The antipathies and invectives of Antisthenes, and especially of his more celebrated follower Diogenes, appear to have been fiercely directed against the elegancies and ornamental superfluities of life; but by no means against such gratifications of the senses as could be obtained without much trouble or expense. The vice of these pleasures, according to their notion, lay not in the indulgence, but in the cost. Anything more thoroughly opposed than all this both to the spirit of general civilization and to the elevation of individual character, it would not be easy to conceive; but the system is very susceptible for all that of a plausible outside representation. It was a not unnatural perversion of the penetrating, sagacious, and sarcastic philosophy of Socrates, by a person of the moral and intellectual construction of Antisthenes. He seems to have been endowed with strong natural powers, but is said to have held all learning and mental cultivation in contempt. It may be supposed, therefore, that his views would be more remarkable for their clearness than their extent. He appears, in fact, to have had more wit than wisdom. He was famous for the brilliancy of his conversation; but although his written works, as Diogenes Laertius tells us, extended to ten volumes (or perhaps treatises, *ῥήματα*), they have all perished. From the list of their titles given by the biographer, they appear to have been mostly rhetorical or sophistical declamations; and, like other such compositions, they had probably plenty of point and smartness, but not much sterling value. Indeed, the only judgment as to their merits which Laertius records is that of a critic of the name of Timon, who thought their author an ingenious trifler. Laertius has enumerated many of the sayings of Antisthenes; but, like the witticisms of the ancients in general, most of them have an elaborate and ponderous air to a modern taste. One which has been often quoted is his sarcasm on the foolish choice of their magistrates and other public officers frequently made by his fellow citizens. He advised them one day, with a serious air,

to set to work and make their asses horses; and when they stared at the absurdity of the proposal, and exclaimed that the thing could not be done, he answered, It will be done if you merely command it; do you not in this way every day do what is quite as wonderful, turning incapables and block-heads into generals and admirals? Another, which illustrates his religious opinions, is his answer to the priest of the Orphic mysteries, when he was assured by that personage that all who should be initiated therein would enjoy eternal felicity after death; Why then, said he, do not you die? He was himself probably sceptical on the subject of a future state. When Diogenes came to visit him a short time before his death, as he lay ill in bed, he eagerly expressed his impatience under his sufferings. Here, said his decisive and unceremonious pupil, offering him a knife, this will relieve you in a moment. Ah! answered Antisthenes, it is not my life I want to get rid of, but my pain. Cicero (*De Naturâ Deorum*, i. 13.) has preserved a theological dogma of this philosopher, which has been often quoted to his honour—*Esse populares deos multos, sed naturalem unum*: That the popular gods are many, but the God of nature is one. It has, however, been acutely remarked by Cudworth, (*Intellectual System*, i. 4, 22,) that by the expression, *populares deos*, here, we are to understand, not the gods of popular superstition generally, or the multitudinous deities of the pagan system, but merely the different names given to the same supreme ruler of the universe by different cities and nations. The meaning of Antisthenes is more clearly expressed in the version of Lactantius, *Unum esse naturalem Deum, quamvis gentes et urbes suos habeant populares*: 'There is one God of nature, though nations and cities have their own popular (peculiar) deities.' Cudworth is of opinion that the philosopher had no design to take away all the inferior gods of the pagans, which, had he attempted, he would have been accounted an atheist, but only to point out the great truth which indeed was acknowledged by all superior minds among the antients (with some exceptions), that there was one God who was supreme over all the rest, and that he was the same whom the Greeks worshipped as Zeus, the Latins as Jupiter, the Egyptians as Hammon, the Babylonians as Bel, the Scythians as Papæus, &c.; as likewise that the Jupiter of the heavens, and the Neptune of the sea, in the popular mythology, were only so many names for this one deity.

The moral maxims of Antisthenes sound, in general, very lofty. He regarded all actions as being either virtuous or vicious, and virtue as the only thing worthy of desire or esteem. Before giving him credit, however, as the teacher of a pure and elevated system of ethics, on the strength of these imposing generalities, it would be necessary to know exactly what he meant by virtue. Diogenes certainly carried the principles of Cynicism to much greater length than his master. The fullest and perhaps the fairest picture we have of Antisthenes is given by Xenophon, who has introduced this philosopher as one of the speakers in his *Συμπόσιον*, or Banquet, and put into his mouth, among other things, a very striking discourse on the wealth of poverty. Altogether he is here represented in a very engaging light.

A few additional particulars respecting this philosopher may be collected from Laertius and other sources. He is said to have had few pupils, and to have treated them with great harshness. Antisthenes has the credit of having set the example to his followers of wearing his beard long, and carrying the staff and satchel, or wallet, (*πήρα*), which afterwards became the distinguishing badges of the sect. He is also stated to have first worn the cloak doubled, (*ἰδίπλωσε τὸν τρίβωνα* and *διπλώσαι θοιμάτιον* are the expressions of Laertius,) whatever that may have meant. It was a fashion likewise practised by his followers, and appears to have consisted in bringing the right end of the cloak a second time over the left shoulder, so as to leave the whole of the right arm, shoulder, and a part of the breast exposed. When the cloak was worn in this manner, the tunic or lower garment was dispensed with; and in this principally seems to have consisted the economy or convenience which recommended the fashion to the Cynics. (See Octavius Ferrarius, *de Re Vestitaria*, part ii., lib. 4, cap. 19, p. 194, edit. Batav., 1654, quarto.) The peculiar name for the philosophic cloak is *τρίβων*, or in Latin tribonium, which signifies literally, a worn or threadbare garment. Antisthenes professed to dislike the haughtiness of Plato; and on one occasion, when the latter had expressed his admiration of a horse,

distinguished by its noble bearing, 'You, Plato,' said Antisthenes, 'would have made an excellent horse.' The father of the Cynics, however, is affirmed on high authority to have had pride enough too, although it might not have been of so elevated a character as that of the founder of the Academy. One day, we are told, when Antisthenes, being in the company of Socrates, had ostentatiously displayed a ragged part of his garment, by way of showing his philosophical contempt for those things of which other men were vain, 'Ah, Antisthenes,' said Socrates, 'I perceive your pride through the holes of your cloak.' Antisthenes is said by Laertius to have had a principal share in bringing Anytus and Melitus, the accusers of Socrates, to punishment. But it has been doubted whether such punishment ever took place at all. (See Barthelemy, *Voyage du Jeune Anacharsis*, chap. 67, note.) Two short orations, entitled *Ajar* and *Ulysses*, attributed to this philosopher, are printed in the *Oratores Græci* of Henry Stephen and of Reiske; and also in Dobson's *Collection*, vol. iv. They are two puerile rhetorical declamations, and, if written by Antisthenes, which we may reasonably doubt, do him no credit.

ANTISTROPHE. [See STROPHE.]

ANTITACTES. [See HERETICS.]

ANTI-TAURUS. [See TAURUS.]

ANTITHESIS, a Greek word (*ἀντίθεσις*) literally signifying 'opposition.' It is used in various senses by the Greek writers: sometimes it means merely 'objections,' or 'opposite arguments;' sometimes it is used to denote the contrasting of one set of circumstances with another: as, for instance, when an orator or other person attempting to place the conduct of an adversary in the worst light, first states what the accused *ought* to have done, and then what he *has* done.

But the term antithesis is most commonly used to express contrast of ideas; and the term is equally applied whether the contrast is effected by single words, or by single clauses. (See Quintilian, *Inst. Orat.*, lib. ix. cap. iii.) The following example from the oration of Demosthenes against Æschines, entitled the Crown, is, in part, quoted by Demetrius Phalereus (*Treatise Περὶ Ῥητορικῆς*, § 262), and by Hermogenes: it is a sample of antithetical invective, in which Demosthenes attempts to show his superiority over his opponent:—'You were employed in teaching, but I was taught: you were a mere menial in the service of religion, but I participated in the sacred rites: you were one of the chorus, but I was the choragus (director of the chorus): you were a petty clerk, but I was a public speaker: you were an actor and played a third-rate part, but I was a spectator: you failed in your part, and I hissed.' This taste for antithesis shows itself very strongly in the Greek language, both in poets and prose writers, and more especially in some of the orators and rhetoricians: but it is generally and justly condemned by the Greek writers on style. The antithesis does not necessarily imply contrariety between the things which are brought together: for example, one of the rhetorical exercises of Gorgias, entitled the *Encomium of Helen*, begins with the following antithesis:—'The ornament of a state is the courage of its men; of the body, beauty; of the mind, wisdom; of action, virtue; of words, truth.' Quintilian (ix. 3) expresses the Greek term *ἀντίθετον* (which is equivalent to *ἀντίθεσις*) by the Latin word *contrapositum*; and he remarks, that the antithesis does not always contain contrarieties or opposites. He gives the following example from the rhetorician Rutilius: 'To us first the immortal gods gave the fruits of the earth: what we alone received, that have we diffused over the whole earth. To us our ancestors transmitted a common wealth: we have rescued from servitude our allies also.' Cicero has the following example of antithesis, which may be compared with similar examples in our own language:—'Quod scis, nihil prodest: quod nescis, multum obest, which may be very imperfectly translated—'What you know, does no good; what you do not know, does much harm.' When antithesis is used sparingly and judiciously, it sometimes gives force to expression, and helps to fix distinctions in the memory; but its frequent and indiscriminate use tends to draw the mind from a true perception of the subject, and to fix it on the play of words more than on the real meaning of the sentence.

ANTI-TRINITARIANS. [See ARIANS, SOCINIANS, UNITARIANS.]

ANTIUM, now called Porto d'Anzo, a sea-port on the coast of Latium, or the Campagna of Rome, once a city of

the Volsci, and noted in Roman history as the place of refuge of Coriolanus. Antium, after having been often the enemy and at times the ally of Rome, was finally taken by the Romans in the year B.C. 337, and became a Roman colony. On this occasion, the *rostra*, or metal beaks with which the prows of the galleys of Antium were armed, being taken as a trophy to Rome, were placed in the forum, as an ornament to the hustings from which the orators pleaded before the magistrates and the assembled people, and which, in consequence, took the name of *rostra*. Horace mentions the Temple of Fortune which rose on the bold promontory within shelter of which the present Anzio is situated. Nero, who was born at Antium, excavated a port and adorned it with fine buildings. He also built here a palace for his wife Poppæa. Remains of ancient masonry are yet to be seen on the point of the cape, and partly in the water. The port having been filled in after-times, Pope Innocent XII. built a mole which serves to shelter vessels of light burthen. There is also a small fort, and a prison for the convicts who are sent here from Rome to be kept at hard labour. The native population of Porto d'Anzo does not exceed 300 inhabitants, and it is altogether a miserable place. The malaria prevails all about the country around in summer, but is not quite so fatal within the place itself, on account of its situation projecting into the sea. From October to June the air is wholesome, and the climate remarkably mild and pleasant. This, together with the beauty of the coast and the fine sea view which extends on one side to the Circean Cape and the island of Ponza, and on the other to the mouths of the Tiber, induced several Roman noblemen about a century since to build palaces and villas near the shore, which now appear neglected and deserted by their descendants. Anzio exports a great quantity of charcoal made from the wood of the neighbouring forests. It is also frequently resorted to by coasting vessels, it being the only place of shelter in bad weather between Gaeta and Civita Vecchia. About two miles S.E. of Anzio is the town of Nettuno, on the sea-coast, with a population of 1200 inhabitants, chiefly sailors and fishermen. The women of Nettuno still retain their old Greek costume. The malaria does not seem to affect the people who live within the walls of Nettuno. Porto d'Anzio is thirty miles S. by E. of Rome; the Alban hills are seen rising to the north about fifteen miles inland. The plain between is divided into enormous farms, one of which, that of Campomorto near Porto d'Anzio, measuring above 17,000 acres, has been visited of late years by various travellers, whose attention had been attracted to its peculiar economy by Chateaubvieux in his *Letters from Italy*.

ANTIVARI, a town in Albania, in European Turkey, on the coast of the Adriatic. It is a little to the N.W. of the mouth of the river Boiana, which forms the outlet of the lake of Skodré (Scutari), and has a good harbour. It was peopled during the middle ages by Italian colonists, and is still the see of a Catholic archbishop. It was taken from the Venetians in 1573; and the inhabitants are now chiefly Mohammedans. They amount to about 4000, and are for the most part seamen, being among the few Albanians who venture on that element; they enter into the naval service of the Barbary states.

Antivari forms the port of Skodré, (from which it is distant about 20 miles,) and is the dépôt of the valley of the Drin, the chief manufacture of which is shoe leather. It is defended by a fortress: $42^{\circ} 4' \text{ N. lat.}, 19^{\circ} 9' \text{ E. long.}$ (Hobhouse, Balbi.)

ANTLIA PNEUMATICA, the air-pump, a constellation in the southern hemisphere, named by Lacaille. It is bounded by Centaurus, Crater, Hydra, Pictis Nautica, and Argo. The magnitudes and numbering of its principal stars are as follows:

Mag.	Letter.	Piazzi.	Ast. Soc. Cat.
6		39	1226
4.5	α	82	1243
5.6		90	249
6	δ	91	2251
6		123	262
6	θ	166	1176
5		199	1299

ANTÆCI, from the Greek, signifies those who live over against each other, and is applied to designate the inhabitants of two places which have the same longitudes and latitudes, only differing in one latitude being north and the other south. For example, Malta and the Cape of

Good Hope are nearly Antæci. Two antæcial places have the same hour of day or night, but opposite seasons of the year.

ANTOINÉ DE BOURBON, Duke of Vendôme, married, in 1548, Jeanne d'Albret, only child of Henry II., king of Navarre. Henry Prince of Béarn, afterwards Henry IV. of France, was the offspring of this marriage. Antoine assumed the title of king of Navarre in right of his wife. The Bourbons were collaterals of the Valois dynasty, being descended from Robert Count of Clermont, a younger son of Louis IX. As such, Antoine de Bourbon aspired to be at the head of the administration of France after the accession of the youthful king Francis II., but being himself of an indolent, wavering disposition, he was supplanted by the more enterprising and ambitious Guises, uncles to the young Queen Mary Stuart. After the death of Francis II., in 1560, the king of Navarre was named Lieutenant General of the kingdom, and adviser to the queen mother (Catherine de Medicis), during Charles IX.'s minority. When the civil and religious war broke out in 1562, the king of Navarre commanded the king's troops, and received a wound at the siege of Rouen, of which he died in November of the same year. [See BOURBON, and HENRY IV.]

ANTOINETTE, (MARIE,) queen of France. [See MARIE.]

ANTONIA MAJOR, the elder daughter of Antonius the triumvir, by Octavia, the half-sister of Augustus, born 39 B.C. She married L. Domitius the son of Cn. Domitius, who supported the interests of Antony in the disputes with Augustus, until a short period before the battle of Actium, and the grandson of L. Domitius, who fell in the flight from Pharsalia. Among the descendants of Antonia were some of the most illustrious personages in Rome. One of her daughters, Domitia Lepida, was the mother of Messalina, afterwards married to the Emperor Claudius; and her son Cn. Domitius, marrying Agrippina, became the father of the Emperor Nero. We have called this Antonia the *elder* in agreement with Suetonius and Plutarch. Tacitus, on the contrary, speaks of her as the younger daughter. (Ann. IV. 44; XII. 64.)

ANTONIA MINOR, the sister of the preceding, born B.C. 38 or 37. She married Drusus Nero, the brother of the Emperor Tiberius, by whom she became the mother, 1. of the celebrated Germanicus; 2. of Livia or Livilla, who was first married to Caius Cæsar, the grandson of Augustus, and after his death to her cousin Drusus, the son of Tiberius; and 3. of the Emperor Claudius. Caligula, being the son of Germanicus, was her grandson.

Antonia was not fortunate in her domestic relations: she lost her husband B.C. 9, before she was thirty years of age, by a fall from his horse. Early in the reign of Tiberius (A.D. 19), she saw the widowed Agrippina return from the east with the ashes of her son Germanicus. In 23, her daughter Livia, corrupted by Sejanus, assisted in the murder of her own husband Drusus, but her guilt remained unknown to the world until eight years after, when Antonia herself became indirectly the cause of the discovery. Sejanus was then preparing to execute his final schemes for the destruction of Tiberius, when his intrigues became known to Antonia, who communicated her information through the freedman Pallas to the emperor. The ruin of the favourite brought many past crimes to light, among others the murder of Drusus; and Livia met the fate which she deserved, her own mother, if we may believe one of the accounts given by Dio, opposing herself to the pardon offered by the emperor. Under the reign of her grandson Caligula, she was at first highly honoured, receiving every distinction which had formerly been conferred on the celebrated Livia. But respect soon changed to coldness and ill-treatment; and at last her death was supposed to be hastened by his neglect, if indeed it was not brought about

by more direct means. If we place her death in the first year of Caligula, she was about seventy-five years of age. The Emperor Claudius had experienced from her when a child little of maternal affection, but he honoured her memory when he came to the throne in every way that the flattery of the age permitted. Pliny speaks of a temple dedicated to her. Of the private life of Antonia little is known. She was celebrated for her beauty, and still more for her chastity, in an age too when that virtue was not common; and Pliny has recorded the singular fact, that during her whole life she was never known to spit, which he accounts for from the more solid nature of her bones, and the want of marrow. The beautiful head of Antonia is taken from a gold medal in the British Museum, which is exactly one half the diameter of our drawing, and in most complete preservation.

ANTONIN (SAINT), a small town in France, in the department of Tarn and Garonne, on the right, or north bank of the river Aveyron, which unites with the Tarn. The inhabitants, who are given in the *Dict. Géographique de la France* (1804) at 5606, and by Balbi (1833) at 5000, manufacture serge and leather. It is about 24 miles N. E. of Montauban, the capital of the department: 44° 10' N. lat., 1° 46' E. long. (*Dict. Géog. de la France*: M. Brun.)

ANTONINE COLUMN, a lofty pillar which stands in the middle of one of the principal squares of the city of Rome. It was raised by the senate in honour of the emperor Marcus Aurelius Antoninus, and in memory of his victory over the Marcomanni and other German tribes. It was one of the principal ornaments of the Forum of Antonine. In an inscription which has been found near it, and which is now in the Vatican, it is styled 'Columna centenaria Divi Marci.' It was also called 'the greater Antonine column,' to distinguish it from another and a smaller one, made of a solid piece of granite, which had been raised in honour of Antoninus Pius. (Nardini and Nibbi, *Roma Antica*, and Vignola, *De Columna Antonini Pri.*) During the ages of barbarism which followed the extinction of the western empire, this pillar, and especially its pedestal, suffered greatly from the hands of the various invaders, as well as from the fires which frequently occurred at Rome; the historian Poggio says also from lightning. Pope Sixtus V. repaired it at the expense of 10,000 scudi, and placed the inscription which is now seen on the pedestal, the original one having been probably defaced. He also raised on the summit of the pillar a bronze statue of St. Paul: that of Marcus Aurelius, which formerly stood there, had been removed it is not known when or by whom. The shaft of the pillar is 13 feet 1 inch in diameter at the bottom, and one foot less at the top; its height, including the pedestal and capital, is 136 feet, of which 13 are under ground; and the statue on the top and its pedestal are 27½ feet more, making the whole height 163½ feet, (Taylor and Cresy's *Architectural Antiquities of Rome*.) The pedestal of the Antonine column is disproportionate to the shaft. The capital is Doric. The shaft is made of twenty-eight blocks of white marble placed one above the other, a spiral staircase of 190 steps is cut through the interior of the marble, and leads to the gallery on the top, which is surrounded by a balustrade. The exterior of the shaft is covered with bassi-relievi placed in a spiral line around, which represent the victories of Marcus Aurelius over the Marcomanni and other hostile nations. One of the most remarkable facts recorded in these historical sculptures is that of the unexpected and abundant shower which came opportunely to quench the thirst of the Roman soldiers, while fighting under their emperor in a remote part of Germany, and suffering from heat, fatigue, and the repeated attacks of the surrounding barbarians, A.D. 174. The style and execution of these sculptures are inferior to those of the Trajan pillar, which the artists evidently purposed to imitate. The sculptures of the Antonine column have been engraved by Santo Bartoli, and illustrated by Bellori. The pillar itself is still one of the most striking monuments of ancient Rome and one of the principal ornaments of the modern city. It has given to the square in which it stands the name of Piazza Colonna. The palace Ghigi forms one side of the square, and the street del Corso forms another. A handsome fountain by Giacomo della Porta also adorns the square.

ANTONINUS PIUS, or, with his full name, according to Capitolinus, Titus Aurelius Fulvus Bojonius Antoninus Pius, was the son of Aurelius Fulvus and Arria Fadilla. He

was born September 19, A.D. 86, in the reign of Domitian, at Lanuvium now *Lavinia*, a town of Latium, a few miles south of the Alban Lake. His ancestors, on his father's side, were of Nemausus, now Nîmes, in Languedoc. His youthful years were spent at Lorium, (a town on the north side of the Tiber, not far from its mouth,) under the care of his paternal and maternal grandfathers, T. Aurelius Fulvus, who had twice been consul, and Arrius Antoninus, who also had twice attained the same honour. It seems probable, from his character in after life, that he had been brought up with great care, and probably in the principles of the Stoical philosophy, which, as emperor at least, he certainly encouraged.

[Gold, Brit. Mus. diam. doubled.]

Through his extensive family connexions he inherited great wealth, and was speedily raised to the successive dignities of quaestor, praetor, and consul. His taste, however, was for a country life. When Hadrian entrusted the administration of Italy to four men of consular rank, he gave to Antoninus the government of that part in which his possessions lay. During his consulship and his subsequent government of the province of Asia as proconsul, there were, as his credulous biographer informs us, many strange presages of his future elevation. On his return to Rome, he was often consulted by Hadrian on public matters; and finally he was adopted as the emperor's successor, on condition of adopting himself, Marcus Antoninus, the son of his wife's brother, and Lucius Verus, the son of Aelius Verus, who had been adopted by Hadrian, but had died prematurely. He then became associated with the emperor in the government of the Roman world. On Hadrian's death, A.D. 138, he became emperor with the title of Antoninus Augustus, to which the name of Pius is added on his medals. As to the origin of the name Pius, his biographer gives various conjectures (see Capitolinus, chap. ii.): the title of Pater Patriæ, 'father of his country,' was subsequently conferred (chap. vi.), and recorded on his medals after the titles of Augustus and Pius. It is unfortunate that the only history of this emperor's life, his *Biography* by Julius Capitolinus, is altogether deficient in that precision and chronological arrangement which would enable us to form a just judgment of the public events of his reign. He seems never to have left Italy after his elevation, but his office maintained the security of the provinces and protected the frontiers from aggression. In Britain, Lollius Urbicus confirmed the former conquests (see ANTONINUS VERUS); the Moors of Africa were compelled to sue for peace; and the attempts at rebellion in Germany, Greece, Judæa, and Egypt, were checked by the vigour of his governors. One of the most curious events in the foreign affairs of the reign of Antoninus is his helping the Olbiae, or inhabitants of Olbia, a Greek colony on the Bosphorus, against a nation called the Tauro-Scythæ, probably a Nomadic race of the Dnieper and the Don. The Tauro-Scythæ were compelled by the Roman emperor to give hostages to the people of Olbia. The emperor died at Lorium in the seventy-fifth year of his age, (seventy-two, according to Capitolinus,) B.C. 161, and was succeeded by Marcus Aurelius, commonly called Antoninus the philosopher. Antoninus was buried in the tomb of Hadrian, one of the architectural monuments with which he adorned Rome.

Antoninus married Annia Faustina, the daughter of Annus Verus, by whom he had four children, one of whom, Faustina, became the wife of M. Aurelius. The conduct of Antoninus's wife gave occasion to scandal, but the good-natured emperor had philosophy enough to endure what he could not prevent. On her death, in the third year of the emperor's reign, the senate paid her the usual compliment of divine honours: a temple, with statues of gold and silver, was decreed by the senate, and

accepted by the husband, to the memory of a wife not altogether faultless. A temple erected to Antoninus and Faustina still exists in part in the Campo Vaccino at Rome. Antoninus even created an establishment for young females, who were called *Faustinianæ*, in honour of the deceased empress. This institution is commemorated in medals that still exist with the inscription *Puellæ Faustiniæ*—the Virgins of Faustina. The general character of the policy of Antoninus was beneficent and just, and the Roman world perhaps never had a more indulgent and amiable master. He continued the governors of provinces for many years in office when their conduct was satisfactory; and the provinces themselves enjoyed under his reign freedom from all exorbitant taxation. He surrounded himself with a council of chosen friends, without whose advice he took no public measure of any kind. Their counsels directed him in drawing up the imperial decrees (*formæ*), which were to have the force of law. Judges who discharged their duty faithfully were never removed. In his elevated station the emperor maintained the simple character of his early life, mingling in the society of his friends like one of the same rank, and using his unlimited power more like a private citizen entrusted with it by his fellow-countrymen than as the undisputed master of the empire. The practice of giving pensions or allowances had grown up under preceding emperors, and had become a part of the imperial system of patronage. Antoninus continued it, and gave, as Capitolinus informs us, salaries and honorary distinctions to the professors of rhetoric and philosophy in all the provinces. Apollonius the Stoic was specially invited from Chalcis to superintend the education of M. Aurelius. But the idle and worthless who had obtained public allowances felt the effect of the prudent emperor's reforms, who remarked, 'that nothing was more disgraceful, nothing more cruel, than for a man to feed on the public property who had done nothing to improve it.' The people and the soldiery participated in the bounty which the policy or generosity of the emperor distributed: he relieved distress in time of scarcity, and for their amusement filled the amphitheatre with animals from all countries. The elephant, the hyæna, and the antelope, with the crocodile, the unwieldy hippopotamus, and the tiger, were exhibited for the gratification of the people. On one occasion a hundred lions at once were let loose into the amphitheatre.

Under the reign of Antoninus, the lawyers, Umidius Verus, Salvius Valens, Volusius Metianus, Ulpian Marcellus, and Diabolenus, were employed by the emperor in improving the laws. One of the emperor's regulations of sanitary police is worth recording: he forbade the burying of dead bodies in cities. With respect to his regulations about physicians, see the article *ARCHIATER*. His policy towards the Christians was mild, but the authenticity of a rescript which would show him to have been completely tolerant, appears not to be proved. (Neander, *Allgemeine Geschichte der Christlichen Religion*, &c., i. 151.)

[Gold, Brit. Mus. diam. doubled.]

Of casualties in his reign, which Capitolinus, like a good chronicler, does not omit, we find enumerated a famine, the fall of a circus at Rome, an earthquake in Rhodes and the province of Asia, and a fire at Rome which destroyed three hundred and forty houses. Narbonne, Antioch, and Carthage also suffered from fire. The emperor's bounty was on such occasions always actively employed in relieving human suffering. He embellished the imperial city with various edifices, and extended his liberality also to remote cities of the empire. Antoninus was tall, and of a handsome person, as his biographer tells us, and his medals still show. His habits were abstemious and regular. He was honoured with the name of *Divus* (God) at his death, and

all the tokens of respect paid to the best emperors. According to the fashion of the times, a special priest, public games, a temple, and a college of priests, as was usual on such occasions, were designed to perpetuate the memory of one of the most amiable princes whom history has recorded. Whether he owes too much to the favourable history of Capitolinus, and the general absence of other evidence, we cannot decide. (See the *Life of Antoninus* by J. Capitolinus; and Schlosser, *Universalhistorische Uebersicht*, vol. iii. pt. i.)

ANTONINUS, THE ITINERARY OF, one of the most valuable works, in a geographical point of view, which has descended to us from the antients. It is merely what its name imports, an itinerary, but it extends over the whole Roman empire in its widest sense, embracing all the main roads in Italy and the provinces, in each of which the different stations are named with the intervening distances. There is also attached to the above a brief maritime itinerary of the distances from port to port. This work, with the Peutingerian Table and the Jerusalem Itinerary, is of great use in constructing the maps of the Roman and Grecian world. In a work of such value it has been an object of some interest to determine the date of its publication and the name of its author; for the name of Antoninus, under which it now passes, has been retained perhaps more from the convenience of having some conventional author to refer it to, than from any good reason for believing that such was really the author's name. In the different MSS. of the work it is variously ascribed to Julius Cæsar, Antonius Augustus, Antonius Augustalis, and Antoninus Augustus. On a consideration of all the arguments adduced by Wesseling in the preface to his excellent edition of the work, there seems to us reason for thinking that some share in the authorship may be ascribed to the three distinguished names, Julius Cæsar, M. Antonius, and Augustus, though such is not the opinion, it should be stated, of Wesseling himself. The main, though not the only argument of Wesseling, seems to be that, had such a work existed in the age of Pliny, it must have been mentioned by him. Negative reasoning of this kind is not of great weight, especially in relation to a writer so incorrect as Pliny. That itineraries of some sort must have existed in the time of Pliny can scarcely admit of doubt. Even in the history of Herodotus we find Aristagoras, the tyrant of Miletus, possessed of a map of the whole world on copper, 'containing every sea and every river'; and this historian himself has given a rough kind of itinerary of the road from Ephesus to Susa, apparently from personal knowledge of the route. Alexander in his march to India was provided with a corps of officers called *Bematistæ* (*βηματισται*), whose especial duty it was to measure the roads and record the different distances. As early as the time of Polybius, the Romans had laid down mile-stones from the Rhone to the Pyrenees; and Strabo says that the great Egnatian road from Apollonia on the Adriatic to the Hebrus was similarly marked by a column at every eight stadia, or Roman mile. Agrippa, among other ornaments of the Roman capital, designed a noble geographical monument in a representation of the whole world on a portico, a design which was completed by Octavia and her imperial brother in the Octavian portico. Even the provincial city of Augustodunum (Autun) had porticoes of the same kind, where maps of every part of the known world with all the names were exhibited to the youth of Gallia. Now if any period were to be selected at which it was probable that the grand work of measuring all the roads in the empire would be undertaken, it would be the moment when the victories of Cæsar in Greece, Egypt, Asia, Africa, and Spain, had at last consolidated the Roman conquests; and he who conferred on his country the great blessing of a well constituted calendar, would naturally direct his mind to the scarcely less important object of a general survey of the empire. But we are not left to conjecture. Æthicus (a geographical writer of uncertain date, but not later than the fourth century, if it be true that St. Jerome translated his *Cosmographia* from Greek into Latin) states in as many words that Julius Cæsar, the author of the bissextile year, ordered a general survey of the empire under a decree of the senate. This was undertaken in three parts, he tells us, the east by Zenodorus, the north by Theodotus, the south by Polycleitus; they began their labours in B.C. 44, the year in which Julius Cæsar and M. Antonius were consuls, and finished them respectively in B.C. 30, 24, and 19, when Augustus, now sole

master of the Roman world, gave the sanction of the legislature to the results by a second decree of the senate. This passage of Æthicus, which certainly bears on the face of it no evidence of forgery or fraud, will well account for the various names prefixed, as above stated, to the MSS. of the *Itinerary*, and it is not impossible that Æthicus himself may have been the editor of the work in the form in which it has come down to us. The *Itinerary* has been found forming part of the same MS. with his *Cosmographia*, and indeed even the authorship of the work has been assigned to Æthicus by more than one writer of the middle ages.

That the *Itinerary*, supposing it to be founded originally upon the above-mentioned public documents, afterwards received many additions and modifications, cannot and need not be disputed. The roads of Britain could not have been all added until the time of Severus, whose *vallum*, or great wall of protection against the Picts, (erected A.D. 209,) is more than once mentioned. The name Diocletianopolis (p. 330) carries us to a period between 285 and 305, and the expression '*Porsulis quæ modo Maximianopolis*,' (p. 321, see also p. 331,) '*Porsulis*, which has been recently changed to Maximianopolis,' leads to the same date. The insertion of the name *Constantinopoli* after that of *Byzantio* affords but weak ground for any argument, as the words *quæ et Constantinopoli*, (p. 139,) and *quæ Constantinopolis* (p. 323) are not found in the Vatican MS. So again the words *a Constantinopoli usque Antiochia* (p. 140) are omitted in the same MS. and condemned by Wesseling himself. These three omissions cannot be accidental. And besides these, there is not a trace of any name marking a period later than the reign of Diocletian, for the station *Candidiana* (p. 223) has no connexion with the son of Galerius, but may rather be compared, as to its termination, with similar forms in pp. 55, 88, 89, 94, &c. On the other hand Cirta, the great city of Numidia, is not called Constantina; Antaratud on the Phœnician coast is not called Constantia. Nor is there any the slightest allusion to the Christian religion which might well have been made in speaking of Antioch; while, on the contrary, we find the names of Juno, (p. 524,) Minerva, (p. 525,) Venus, (p. 526,) Apollo, Diana, and Vateria (pp. 527, 529).

As a specimen of the work, we quote a few lines which may be interesting to the reader of Horace's amusing journey to Brundisium. In this extract it will be seen that little regard is paid to the grammatical cases; but this is not an evidence of a very late age, for even before the time of Constantine it had become not uncommon to consider the names of places as indeclinable, and the case selected to serve for all was generally the accusative or ablative. The numbers within brackets mark a variation in the MSS., some of which admit of easy explanation, but the occurrence of these errors in the number of miles is the chief drawback from the value of the work. The road commences from Rome.

ANTONINUS, WALL OF. This was an entrenchment raised by the Romans across the north of Britain under the direction of Lollius Urbicus, legate of Antoninus Pius, about the year A.D. 140, and is supposed to have connected a line of forts erected by Agricola, A.D. 80. Of ancient writers, it is noticed by Julius Capitolinus only, and by him is termed a turf wall (*murus cespitiis*). The work

was composed of a ditch, a rampart with its parapet, made of materials promiscuously taken from the ditch, and a military way formed with much skill, running along the whole line of the entrenchment at the distance of a few yards on the south side. It extended from Dunglass Castle on the Clyde to the heights above Caer Ridden Kirk, a little beyond the river Avon on the Frith of Forth, or probably to Blackness Castle two miles farther on, though it cannot now be traced so far. In its course are nineteen forts, the eighteen distances between which amount to 63,980 yards, or 36 English miles, and the mean distance from station to station is 3554 yards, or rather more than two English miles. In the position of the forts, the Romans chose a high and commanding situation from whence the country could be discovered to a considerable distance, contriving, as far as circumstances would permit, that a river, morass, or some difficult ground should form an obstruction to any approach from the front. Forts were also placed upon the passages of those rivers which crossed the general chain of communication. From inscriptions discovered in Scotland, it appears that the entrenchment was made by the second legion, by vexillations of the sixth and the twentieth legion, and the first cohort of the Tungri. A very considerable portion of the entrenchment may still be traced. The modern name is Grimes Dyke; Grime, in the Celtic language, signifies great or powerful. (See General Roy's *Military Antiquities of Britain*; and Horsley's *Britannia*.)

ANTONINUS LIBERALIS, probably lived under the Antonines. He is the author of a work in Greek entitled *A Collection of Metamorphoses* (*Μεταμορφώσεων συλλογή*); this collection is borrowed from a variety of authors, and is curious for containing many passages of poets who are now lost. The best edition is said to be that of H. Verheyk, Leiden, 1774. 8vo. See Bast's *Epistola Critica*.

ANTONIO, MARC. [See RAIMONDI.]

ANTONIO, one of the claimants to the throne of Portugal after the death of King Sebastian, was the natural son of the Infante Don Luiz, son of King Manuel. Antonio accompanied his cousin, King Sebastian, in his unfortunate expedition to Africa, and was there taken captive in 1578. He had the ability to conceal his real name and rank, and consequently had less difficulty in obtaining his deliverance.

On his return to Lisbon he found his uncle, Cardinal Enrique, who had been appointed regent by Sebastian, in possession of the throne. Antonio immediately claimed the crown on the plea that his father had secretly married his mother. Enrique ordered him to produce the proofs, which were found to be forgeries. By the advice of the pope's nuncio, Antonio excepted against the judgment of the king, and appealed to the Archbishop of Lisbon, reserving the final decision to the pope. The cardinal-king declared Antonio a traitor, degraded him from his rank, and exiled him from Portugal. Antonio fled to Spain, where, however, he did not remain long. He there solicited an interview with the Spanish minister, and offered to give up his claim to the king of Spain, Philip II., for an annual pension of 300,000 ducats and the regency of Portugal during his life. This extravagant proposal was naturally rejected. In the mean time the cardinal-king assembled the cortes of the realm at Lisbon, in April, 1579, to decide the question of the succession. He also appointed a council of eleven judges to examine the rights of the respective claimants, and named a regency to govern the kingdom in case his death should take place before the cortes had come to a final decision. All the candidates bound themselves upon oath to abide by the resolution of the cortes, but before they had pronounced their judgment, the king died, on the 1st of January, 1580.

The cortes was at this time at Almerin. Antonio, who had already returned from Spain, hastened immediately to Lisbon, where he summoned the authorities to receive him as king. Not succeeding here he repaired to Santarem, where the deputies of the third estate had removed from Almerin; and he flattered their vanity by telling them that the power of appointing the successor rested in them alone. He then invited the inhabitants of the towns in the vicinity of Santarem to repair thither, and proposed to them to recognize him as governor of the kingdom. One of his own servants put a rag on the point of his sword, and hoisted it, crying, *Real, real por Dom Antonio*; the word was caught by the multitude, and he was proclaimed king.

Antonio now proceeded to Lisbon. The regents fled at

his approach, and he was proclaimed king in the capital also. The regency went to Setubal, where they found that the people had declared in favour of Antonio. The new government proclaimed the regents as rebels, and a detachment of cavalry was sent in pursuit of them. But the Duke of Alba at the head of the Castilian army, in the mean time, invaded the kingdom to take possession of it in the name of Philip, and reduced Elvas, Villaviciosa, Estremoz, Montemor, and other places. Alcazar do Sal also opened its gates to the Spaniards, and Setubal afterwards followed its example. The Marquis of Santa Cruz with the Spanish fleet had also taken possession of other places on the coast. Antonio, at the head of 12,000 men, courageously opposed the invaders, but he was defeated, and the duke entered Lisbon by capitulation. Antonio retreated to Coimbra, and on the inhabitants refusing to admit him, he went to Aveiro, plundered the town, and proceeded to Oporto, where he knew he had some adherents. The success of the Castilian arms, however, had so changed the dispositions of the inhabitants, that they had offered to surrender the town to Philip, and openly refused to admit Antonio. But some of his partisans having opened one of the gates, he entered the town like an enemy, and his soldiers committed the most violent excesses. The Spaniards soon arrived before Oporto. Antonio had only 3000 men, chiefly recruits, who fled before the Spanish veterans, and both conquerors and conquered entered Oporto together. In this hurry and confusion, Antonio escaped to Viana do Minho, where he embarked; but the sea was so rough that he was forced back to land. He was now placed in a very perilous situation. A large body of cavalry was in pursuit of him, and the sum of 80,000 ducats was offered for him dead or alive. In this situation he disguised himself in a sailor's dress, and by mixing only with the lower orders, he was able to remain for some months in Portugal, going from one town to another, until at last he escaped to France.

At Paris, he published a manifesto in Latin, French, and Dutch, and sent it to Holland and England, from which quarters he expected some assistance. This document bears the date of 1585. In 1588 he came to England, soon after the destruction of the Spanish Armada. He was favourably received by Queen Elizabeth, and though she at first refused him any effectual assistance in invading Portugal, she was at last persuaded to equip a fleet in which she sent the exile back to his country. If we are to believe the Portuguese and Spanish historians of the period, the proposals of Antonio were most monstrous. They say that he offered, among other things, to receive English garrisons into all the principal places of Portugal, and to maintain them at his own expense; to abandon the city of Lisbon to twelve days' pillage, and even to bestow the principal offices in the kingdom on Englishmen. In 1589, the expedition, consisting of 120 vessels with about 20,000 volunteers, sailed from Plymouth under the command of Sir Francis Drake and Sir John Norris. After having attempted in vain to take Coruña or Corunna, they anchored at Peniche, about twelve miles from Lisbon. The troops were safely landed, and part of them marched under their commander Norris towards Lisbon, while the admiral went up the river with the remainder. The land forces in their march found that the people, instead of joining them, as Antonio had promised, fled at their approach. They advanced, however, as far as the capital, without opposition, and assailed the fortworks; but the garrison making a vigorous sortie, the English general commanded his men to retreat; some of them were cut off, and he saved himself, with the remainder, in the fortress of Cascaes. Here, both from want of provisions, and from feeling that they had been disappointed by Antonio, whose cause they now considered desperate, the English determined to return home. Antonio retired to France, where he ended his days in obscurity and indigence. On the 26th of August, 1595, deserted by his friends, and neglected by all the sovereigns who formerly had espoused his cause. (See Lemos, *Historia General de Portugal*, vol. vii.; Antonio de Herrera, *Historia de Portugal*; Mariana, *om* the year 1578 to 1590.)

ANTONIO (NICOLAS or NICOLAO), a Spanish writer, born at Seville, in 1617. He received his early education at the Dominican school of that city, where he also studied divinity two years. In 1636 he went to the university of Salamanca, where he studied civil and canon law under the celebrated jurist Ramos del Manzano. In 1639 he was made a bachelor of arts. He returned afterwards

to Seville, and devoted his time entirely to collect materials for his *Bibliotheca*. In 1646 he was created a knight of Santiago, and in 1659 Philip IV. appointed him general agent for the court of Spain at Rome, which office he held with honour until he was recalled by Charles II. He was then made a canon of Seville, and created a counsellor of Castile. He resided afterwards for some time at Seville; subsequently, he went to Madrid, where he died of epilepsy on the 13th of April, 1684. He has left behind him the following works:

1. *De Exilio, sive de Exilii pœna antiqua et nova, Exulique conditione et iuribus. Libri tres; cum indice: Antwerpiae, 1641 and 1659.*—*Of Banishment, or of the Punishment of Exile, Antient and Modern, and on the Condition and Rights of the Exiled:* Antwerp. Antonio was twenty-three years of age when he wrote this work.

2. *Bibliotheca Hispana*, the best and most complete edition of which bears the following title: *Bibliotheca Hispana, vetus et nova, sive Hispanorum Scriptorum, qui ab Octaviano Augusti ævo ad Annum Christi MDCLXXXIV. floruerunt, Notitia. Curante Francisco Perezio Buyerio. Matriti. Joachimus Ibarra. 1788. 4 vols. folio.*—*Bibliotheca Hispana, Antient and Modern, or an Account of the Spanish Writers who have flourished since the age of Octavianus Augustus to the year 1684.*

3. *Censura de Historias Fabulosas. A Criticism on Fabulous Histories.*

The principal work of Antonio is his *Bibliotheca*. Baillet says that he prefers it to all the works of the kind in existence, not excepting that of L'Alegambe. 'The criticism of the author,' adds he, 'is correct, his Latin pure, his style elevated, though now and then it is obscure on account of his long parenthetical phrases.' This judgment is, in our opinion, correct, and, for Spanish literature, there is certainly neither a better nor a safer guide.

Antonio was a man of a liberal and charitable disposition: notwithstanding the lucrative offices he had held, he died so poor that he did not leave his heirs sufficient property to enable them to print part of the works which he left unpublished. Cardinal Aguirre, the author's friend, defrayed the expenses of the work. (See the author's own book; the *Biogr. Univ.*; and Bayle's *Dictionary*.)

ANTONIO, ST., the most northerly of the CAPE VERDE islands.

ANTONIUS, MARCUS, the orator, was born 142 B.C.; in 99 he was the colleague of C. Postumius Albinus in the consulship; and in the following year he defended M. Aquilius on a charge of extortion during the servile war in Sicily. In 97 he was censor, and he fell a victim to the fury of Marius and Cinna, when they took forcible possession of Rome in 87. His eloquence is celebrated by Cicero in his *Brutus*, chap. 37. 38. Two of his sons appear prominently in the history of Rome.

ANTONIUS, MARCUS, son of the orator, and father of the Triumvir. When the short-lived power of Mithridates over the Grecian islands had been put an end to by the successes of Sulla and his lieutenants, in the absence of a controlling fleet a general system of piracy arose in the Grecian seas and the adjoining coasts. This evil proceeded to such a degree, that in the year 75 B.C., through the influence of the Consul Cotta, Antonius was intrusted with the extraordinary province of protecting all the coasts of the Mediterranean. Crete was the chief scene of his operations, and though his successes for a time gained him the honorary title of Creticus, the outrages and extortion of which he was guilty, led at last to an insurrection in which he lost his life, about B.C. 69; and the credit of reducing the island was reserved for Metellus.

ANTONIUS, CAIUS, surnamed Hybrida, another son of the orator, was the colleague of Cicero in his consulship (B.C. 63). It became his duty, under the orders of the senate, to conduct the war against Catiline; but on the day of the battle he was prevented, or pretended to be prevented, by illness from appearing on the field, and the command devolved upon his lieutenant, Petreius. On the termination of the war, he proceeded (B.C. 61) as proconsul to the lucrative province of Macedonia, which had originally fallen to Cicero's lot, but had been transferred by him to Antonius, from a patriotic desire to attach him to the cause of his country. Such, at least, is the assertion of Cicero. Antonius, on the contrary, gave out that it was a matter of mere bargain and sale, and that Cicero had stipulated for the payment in return of a large sum of money, a charge which Cicero's ambiguous

language and conduct on the occasion seem not to discountenance. To raise this money, Antonius was guilty of great extortion, and his conduct gave such general dissatisfaction, that at the end of the first year Pompey threatened a motion in the senate for his recall. Cicero, who avows in his private letters that he could not defend Antonius without injury to his own character, nevertheless exerted his eloquence most powerfully and successfully in his defence. Accordingly, Antonius held the province for a second year; but on his return (B.C. 59) he was formally brought to trial by Cælius on a charge of extortion, and of carrying on war out of his province without the authority of the state. Though again defended by Cicero, he was found guilty, and condemned to perpetual exile. The trial took place on the very day that Clodius was adopted into a plebeian family, and thus enabled to direct his attacks successfully against Cicero.

ANTONIUS, MARCUS, the Triumvir, was the son of M. Antonius, surnamed Creticus, and Julia, a member of the patrician house of the Cæsars, sister of L. Julius Cæsar, the consul of 64 B.C. The year of his birth is somewhat uncertain, being assigned by different authors to 86, 83, and 81 B.C. His father dying while he was yet young, he received the greater part of his education under the direction of his mother Julia, who was at that time married to Cornelius Lentulus.

[Gold, Brit. Mus. diam. doubled.]

In his very outset into life Antony had the misfortune to form an acquaintance with young Curio, and the two friends entered upon such a course of extravagant dissipation that Antony was soon deeply involved; but Curio, being surety for the debt, prevailed upon his father, by the intercession of Cicero, to discharge it. Among the Roman nobles who were put to death by Cicero as accomplices of Catiline, one of the most distinguished was Antony's step-father, Cornelius Lentulus, then prætor of Rome. He was probably guilty; but the consul and the senatorian party had still more certainly violated the laws in putting citizens to death without trial. It was natural, then, that Antony should attach himself to Clodius, when that powerful tribune (whose character, it may be observed, should not be taken from his unscrupulous enemy) was employed in bringing Cicero to punishment. But Antony did not approve of the violence to which Clodius resorted. Accordingly, he went over to Greece, where he diligently applied himself to the two pursuits most important to a Roman, oratory and military science. From thence he was invited to join Gabinus, who, as proconsul of Syria, was engaged in protecting his province from the ravages of Aristobulus and his son Alexander (B.C. 57, 56). Antony in this war commanded the cavalry, and evinced great spirit and military talent. In the course of the following year, Gabinus undertook to restore Ptolemy Auletes to the throne of Egypt, and again the credit of his success was chiefly due to Antony, who secured the only road from Syria into Egypt, and made himself master of Pelusium. Here he showed a goodness of disposition, for which history has rarely given him credit, in saving the inhabitants from the furious revenge of Ptolemy. Gabinus returned to Rome in the autumn of 54, but Antony, who had now established his reputation as an officer, as soon as hostilities ceased in Egypt, hastened at once to Gallia, the theatre of a still more important war. In the year 52 we find Antony acting as one of Cæsar's lieutenants at the siege of Alesia. He now became a candidate for the quæstorship, and even aspired to the place in the college of augurs, then made vacant by the death of Crassus. His pretensions to the latter office he withdrew in favour of Cicero, who, at the intercession of Cæsar, was reconciled to Antony, and promoted his election to the quæstorship,

while he in return opposed the turbulent conduct of Clodius. No sooner was Antony's election completed than he hastened back to Gallia, where, at the close of the year, he was left by Cæsar at the capital of the Ædui in the command of the troops there quartered. The following year he was employed under Cæsar in extinguishing the last embers of the Gallic war; and so fully had he gained the support of the general, that through his interest and that of Curio he was elected early in 50 B.C. into the college of augurs.

The senatorian party meanwhile had withdrawn Pompey from his friendship with Cæsar, but the tribunitial power was still a check upon their arbitrary proceedings, and through the influence of the same powerful friends Antony was raised to that dignity. The tribunes entered upon their office on the 10th of December, whereas the consular authority commenced upon the first day of the year. Antony employed this interval in advocating the just rights of Cæsar with the people. When the kalends came, however, the senatorian party put to the vote the fatal motion that Cæsar should disband all his troops by a given day, or be treated as a public enemy. Antony and his colleague Cassius interposed their tribunitial veto, but the senate was now prepared to break down all the popular barriers of the constitution; the two tribunes were allowed but six days to consider their veto, and on the 7th of January the decree was passed which at once suspended all the laws of the state, and gave to the senatorian party despotic and irresponsible power over all the citizens. The tribunes, thus at the mercy of tyranny, fled in disguise to Cæsar, whose army in a few weeks drove the authors of the late revolution from Italy. On the first expedition of Cæsar into Spain, Antony was left in the military command of Italy, which was again intrusted to him in the winter of the same year, when Cæsar crossed into Epirus. In the performance of this duty he distinguished himself by his able defence of Brundisium and its port against a Pompeian fleet under Libo, and soon after he crossed the Adriatic with reinforcements for Cæsar. In this campaign he on many occasions rendered the most efficient service, particularly at the battle of Pharsalia, where he commanded the left wing. In the following year, Cæsar, being appointed dictator, selected Antony as his master of the horse, an appointment which again gave him the chief authority in the absence of the dictator. During this period he showed his firmness in checking the violent proceedings of Dolabella. Plutarch, indeed, attributes his conduct to a mere feeling of revenge, in consequence of a supposed intrigue between Dolabella and his wife Antonia, for he had married his own cousin, the daughter of C. Antonius Hybrida. He accordingly divorced Antonia, and gave way to the most open licentiousness, about which Cicero's second *Philippic* abounds with scandalous anecdotes, exaggerated however most probably by the malice of the orator. One of the most outrageous acts, recorded by Pliny, was his appearance in public with an actress named Cytheris in a car drawn by lions. When Pompey's property was confiscated, Antony had purchased his house and grounds in the street called Carinæ at Rome, under the idea, says Cicero, that the money would never be demanded, and when Cæsar insisted on the payment, he was obliged to sell a large portion of his property, including a patrimonial estate at Misenum, to raise the required sum. To the fact that Antony occupied Pompey's house, there are frequent allusions in Cicero's speeches and the anecdotes of Plutarch. Antony soon broke off his connexion with the Grecian actress, which had been the cause of so much scandal, and married Fulvia, the widow of Clodius. During the second war in Spain (45 B.C.) against the sons of Pompey, when Cicero was induced by some exaggerated accounts of their successes to meditate an escape from Italy, he was checked by the interference of Antony, whose letter on the occasion still exists. The next year Antony was the colleague of Cæsar in the consulship, but the senatorian party again dreamed of recovering their power, and the idle affair of the Luperæalia was seized as a pretext for the conspiracy against Cæsar. At one time there was a desire on the part of the conspirators to admit Antony into their body, but this was prevented by Trebonius, on the ground that he had himself made some advances to Antony the very preceding year on his subject, which had been decidedly rejected. This fact is one proof of the little foundation which Cicero thought necessary for the grossest charges. He has not scrupled to accuse Antony of joining Trebonius in a conspiracy to murder Cæsar, when we have the authority of Trebonius

himself, as reported by Plutarch, for the opposite statement. As Antony was not likely to join in the crime, it was next proposed to make him also a victim, but this was prevented by M. Brutus; and it was finally determined to engage him in conversation outside of the senate-house while the assassination of Cæsar was committed within.

Antony, a man of spirit, but of prudence, saw that it was necessary to act guardedly with men who accomplished their ends by assassination. He amused them, therefore, for a time with the most conciliatory conduct, knowing, perhaps, that the people would soon recover from their first alarm and rise against the murderers of their benefactor, more particularly the veterans who now feared to lose again the rewards of all their past labours. We omit to enumerate a number of acts on the part of Antony, such as his receipt of Cæsar's treasures from Calpurnia, his speech over the body of Cæsar, his publication of decrees, real or pretended, as in the name of Cæsar, because a much greater effect was attributed to these acts than they could of themselves have produced. The real power of Antony lay in the detestation in which the senatorian oligarchy was held. The self-styled patriots were soon afraid to appear in Rome, and Antony, supported by his two brothers, Caius and Lucius, who happened at this time to hold the offices of prætor and tribune respectively, had a prospect of establishing himself in a station scarcely inferior to that from which Cæsar had been thrown down. But he found his most powerful opponent in young Octavius (afterwards Augustus), the great-nephew and adopted son of the late dictator, who, with a duplicity beyond his years, managed to unite the support of the most opposite parties, the oligarchy and the veterans. Utterly unscrupulous about his means, he made no attempt, at least Cicero gives his authority to the report, to remove Antony by assassination. After numerous intrigues on all sides, Antony left Rome in October to meet at Brundisium four of the veteran legions from Greece; but Octavius, or, as he now called himself, Cæsar, found other veterans in the colonies of Campania ready to support one who bore so auspicious a name; and two of the four legions from Greece suddenly passed over to him from Antony. Before the year was closed, hostilities commenced in the north of Italy, where Antony besieged Decimus Brutus in Mutina. On the 14th of April, B. C. 43, the first battle was fought, when Antony, after defeating Pansa, was himself the same evening defeated by Hirtius. A few days after, he was again defeated in a twofold attack from Hirtius and Cæsar on the one side, and D. Brutus on the other, and compelled to cross the Alps.

The senatorian party were already enjoying their triumph, when the scene unexpectedly changed. The two consuls had fallen in the late contest. Decimus Brutus, though relieved from the siege, was without cavalry or commissariat, and unable to pursue; and Cæsar, never sincere in the use of the senate, and himself supported by the senate only for their own purposes, at last threw off the mask. Ventidius had joined Antony with three legions, and the presence of the latter was sufficient to gain over the troops.

Lepidus, then stationed in the south-eastern angle of Gallia, even if Lepidus was earnest in opposition to him. Finally, Plancus on the Isara and Pollio in Spain, after a long hesitation, declared themselves likewise in favour of the more powerful party. Thus Antony, who had fled from Mutina, with a strong body of cavalry indeed, but with not more than a single legion, if we exclude the unarmed, now traced his steps across the Alps at the head of seventeen legions, the greater part veterans, leaving behind him six cohorts to guard the important province of Gallia. Decimus Brutus, on the other hand, had only ten legions to oppose him, and of these eight were from the recent levies and all doubted fidelity. In the mean while, Cæsar had put an end to the equivocal conduct of the senate by marching on Rome, and extorting the consular fasces.

In the autumn of this year the celebrated triumvirate was established between Antony, Lepidus, and Cæsar, sometimes called the second triumvirate, but without sufficient reason, as the private understanding between the first Cæsar and Pompey and Crassus never assumed a public character. Antony and his colleagues, on the contrary, received no title under a public vote at Rome, and made use of it all their public acts. In the proscription, which was one of the first acts of the triumvirate, Antony, whose conduct on so many occasions was distinguished for clemency and generosity, must bear his share of the guilt, more par-

ticularly in relation to Lucius Cæsar and Cicero. The former of these, his maternal uncle, was saved indeed by the bold interference of his mother, Julia; but Cicero, who had escaped from Rome when Cæsar appeared there with his army, was overtaken by his pursuers on the coast, and his head and right hand were cut off and fixed on the rostra of the Roman forum. But it is no slight palliation of the crime of proscribing this orator, that he had more than once in his life advocated the principle of assassination, and particularly had expressed, in language of the most brutal ferocity, his regret that Antony had not been murdered with Julius Cæsar. His private letters, as well as his public speeches, contain repeated assertions to that effect in all the various figures which his oratorical skill could supply. But Antony felt soon after the natural consequence of his crime, when his brother Caius, who had been some time a prisoner in the power of Marcus Brutus, was put to death in revenge of the murder of Cicero.

In the division of the provinces between the triumvirs, Antony received the whole of Gallia Citerior and Ulterior, with the exception of Gallia Narbonensis. To him and Cæsar was assigned the conduct of the war against Brutus and Cassius; and in the following year this war was brought to a close by two battles in the neighbourhood of Philippi, in both of which the success was due almost exclusively to Antony. Among the distinguished Romans who fell into his power on this occasion was the son of the orator Hortensius, who had been the instrument of Brutus in putting his brother to death. He ordered the prisoner to be slain upon his brother's tomb,—an act of revenge which, however criminal in itself, the Roman notions of piety perhaps required. Antony remained some time in Greece, particularly at Athens, where he ingratiated himself with the citizens. He then crossed into Asia, and Ephesus became the scene of more than Asiatic luxury. At Tarsus he saw the fascinating Cleopatra, whose influence so fatally affected his fortunes. He had summoned her to answer some accusations brought against her of assisting Cassius in the late war; and the queen, in obedience to the command, appeared in her gorgeous barge upon the Cydnus attired as the goddess Venus. Antony was led captive to Alexandria, where he lost sight of all that was going on in the world around him. He was at last roused from his voluptuous revels by a Parthian invasion on the one side, and a war in Italy on the other. A Parthian army under the guidance of Labienus, a Roman of the senatorian party, who had accidentally been absent from the battle of Philippi, had overrun all the provinces from Syria to Asia. Antony set out to oppose them, but had scarcely arrived in Phœnicia when he was induced by the urgent solicitations of Fulvia to proceed with a fleet of two hundred sail towards Italy to oppose Cæsar. But the war in this quarter was at an end before his arrival: Perusia had fallen. The death of Fulvia, who, with Antony's brother Lucius, had been the chief cause of the war, led to a speedy reconciliation between Antony and Cæsar, which was cemented by the union of Antony with Octavia, the half sister of Cæsar, herself but recently a widow by the death of Marcellus. On this occasion a new division of the empire was made, in which Antony received as his portion all the provinces east of the Adriatic. In the following year, another step was gained towards securing the peace of the empire by a treaty with Sextus Pompeius, whose fleet had given him the command of Sicily and other islands.

Leaving the management of affairs at home to Cæsar, Antony proceeded with Octavia to Greece. Here he heard that his lieutenant Ventidius, to whom he had left the conduct of the Parthian war, had been highly successful, that the invading army had been defeated, and that Labienus had fallen in the battle. In the following year (38) the same able officer gained a still more decisive victory over the Parthian prince Pacorus, who had invaded the Syrian province,—a victory the more gratifying to the Romans because it occurred on the same day of the year as the defeat of Crassus fifteen years before. As these successes had been obtained by a lieutenant under the auspices of Antony, the latter was entitled, by the established principles of Roman warfare, to the honour of the triumph; but Antony, guided by a more generous feeling, sent Ventidius to Rome to enjoy this honour. Another of his lieutenants, Sosius, was scarcely less successful in a Jewish

* It is almost certain, that he had previously seen her at Rome, where she was residing at the time of Cæsar's death. Antony was at that time consul.

war against Antigonos, for which he likewise triumphed a few years after (34 B.C.); and a third, Canidius, had recovered Armenia, and carried the arms of Rome to the foot of the Caucasus. On the other hand, the siege of Samosata, which was partly conducted by the general in person, rather detracted from than added to his military fame by the long and determined defence of the Commagenian prince Antiochus. But Antony was again called to Italy by the suspicious conduct of Cæsar. On his approach to Brundisium he was refused admittance into the harbour, on the ground that he was accompanied by Domitius, who, it was pretended, had been a party in the murder of the dictator. After much angry discussion and some hostile movements, a second reconciliation was effected by the mediation of Octavia, and Julia, the mother of Antony, who at the same time belong to the House of Cæsar. This new arrangement took place at the end of 37, or in the following spring. The most important article was the renewal of the triumviral power for a second period of five years, commencing from the last day of the year 38, the day on which the first period of their triumvirate terminated. Cæsar now conducted the war against Pompey, while Antony directed his arms against the Parthians. On his approach to Syria he sent for Cleopatra, on whom he conferred the provinces of Phœnicia, Coëlesyria, Cyprus, and part of Cilicia, Judæa, and Arabia. His preparations for the invasion of the Parthian empire were on the largest scale, but the influence of the Egyptian queen produced the most disastrous effects. The army commenced their march too late in the season, and after a campaign in which the soldiers showed the greatest spirit, and the general, on some occasions, no little military talent, the retreat was effected with great loss, partly through the eagerness of Antony again to meet Cleopatra.

The failure of this campaign had been in a great measure owing to the treacherous desertion of the king of Armenia. Accordingly, in the following year, Antony was anxiously looking out for an opportunity of revenge, and a quarrel between the king of Media and the Parthians seemed to offer a favourable opportunity. The prospect of a war at any rate afforded him a pretext for avoiding an unwelcome visit from Octavia, whom he directed to remain at Athens, while he added to the insult by still dallying with Cleopatra at Alexandria. The following year, the invasion of Armenia took place, and by treachery, in his turn, Antony got the king into his power. In the mean time, Cæsar, by the overthrow of S. Pompeius and the usurpation of the provinces assigned to Lepidus, was at last prepared for a contest with Antony himself, who afforded him more than a pretext by the neglect of his sister and his conduct at Alexandria, where he seemed wholly to have exchanged the character of a Roman citizen for that of an eastern monarch.* In 33, Antony again commenced an invasion of Parthia, but as soon as he had reached the Araxes, he retraced his steps to prepare for the war that now threatened him from the west. Still a second year was passed in preparations; and in 31, the possession of the Roman world was decided by the victory off Actium. (See ACTIUM.) From that day the fate of Antony was fixed. In August, 30 B.C., Cæsar appeared with a fleet and army before Alexandria, to which Antony had retreated; and the desertion of his fleet and of his cavalry before his eyes left him only the poor hope of sustaining a siege. A false report of the death of Cleopatra completed his despair, and he killed himself with his own sword. Cleopatra likewise saved herself by suicide from adorning the triumph of the conqueror. It was a singular coincidence that the account of Antony's death was laid before the senate by M. Tullius Cicero, the son of the orator, who assumed the consular fasces on the ides of September. Antony's age at his death was a little more than 50; that of Cleopatra 39. He was four times married, or indeed, five times, if we may admit his marriage with Fadia, on the authority of Cicero. Of his two children by Fulvia, Antyllus the elder was put to death; and the younger, Iulus Antonius, to whom Horace has addressed an ode, after long enjoying the favour of Augustus, suffered for his intimacy with Julia, the emperor's daughter. By Octavia, he had at least two daughters (see ANTONIA); and by Cleopatra, a daughter of the same name, and two sons, Alexander and Ptolemy Philadelphus. Of these, the

* On one of the medals given in this article we see the face of Antony and Cleopatra on opposite sides; the characters on the medal are Greek. As Antony here calls himself one of the triumviri, it was probably struck before the downfall of Lepidus.

daughter married the learned African prince Juba. (See Cicero's *Letters and Orations*; Cæsar; Velleius; the *Epitomes* of Livy; Plutarch's *Life of Antony*, *Dion*, *Appian*, &c.; and Clinton's *Fasti*.)

The heads of Antony and Cleopatra are taken from a silver coin in the British Museum, in which the expression of Cleopatra's face fully agrees with the assertion of Plutarch, that her fascinating powers depended not so much on her beauty, in which she was inferior to Octavia, as on the charms of her manner and conversation. Plutarch also mentions the remarkable aquiline nose of Antony.

ANTONIUS MUSA. [See MUSA.]

ANTRIM, a county in Ireland, bordering on the coast at the N.E. extremity of the island, and in the province of Ulster. It is bounded on the N. by the Atlantic, on the E. by the north channel, (which forms the northern entrance into the Irish Sea, and separates Ireland from Scotland,*) on the S.E. by Belfast Lough, on the S. by the county of Down, on the S.W. by Lough Neagh, and on the W. by the county of Londonderry, from which it is separated for the most part by the river Bann.

This county extends from N. to S. 56 miles, and from E. to W. 30½ miles; and contains, according to the trigonometrical survey now making under the direction of the Board of Ordnance, 758,808 acres, of which only 483,048 are arable, 225,970 being mountain and bog, and 49,790 under water. The sea-coast is romantic and picturesque. Near the western extremity of that part of it which belongs to this county, is the 'Giants' Causeway,' an immense pile of perpendicular basaltic columns, varying in their number of sides, but chiefly hexagonal, touching each other on every side without intervals or void spaces, and forming a huge mole or pier which extends far into the sea. (Hamilton's *Letters concerning the Coast of Antrim*.) [See GIANTS' CAUSEWAY.] Other specimens of columnar basalt are found along the coast, as at the promontory of Bengore in the neighbourhood of the Giants' Causeway, and at Fairhead, a headland about eight miles east of the last; also in some places inland. From Fairhead, the coast, which runs so far nearly W. and E., turns to the southward to the entrance of Belfast Lough, and presents to the eye a succession of precipitous cliffs projecting boldly into the ocean, and broken by a few bays and creeks. Off the coast lie the islands of Skerries, and Rathlin or Raghery. The Skerries are small islands W. of the Giants' Causeway. Rathlin is larger, being seven miles in length, and containing about 2000 acres, of which about 500 are arable. It is crescent-shaped, with the horns turned towards the main-land, from which it is separated by the strait of Slunk-na-marra;—the passage of this strait is often dangerous from the heavy swell. The inhabitants, who amount to 1080, are engaged in fishing, raising barley, or manufacturing kelp. At Doon Point, in this island, are some singular basaltic columns, horizontal, perpendicular, and curved. The eastern side of the county is mountainous, but the mountains form irregular groups rather than a continuous chain, and are intermixed with bogs, which also prevail in the western and flatter part of the county. The principal heights are Slemish, about the middle; and Knocklayd or Knocklead, in the northern part of the county. There is a popular opinion that Belfast is subject to much rain; but this opinion is owing rather to the frequency of the showers than to the actual quantity of rain that falls, which in the years 1795-98 was much below that at Londonderry in the adjoining county to the west.

There are no rivers or streams of any importance running through the county. The largest are the Bush, which, rising in the mountainous district to the N.E., near Knocklayd, flows first to the west and then to the north, and falls

* The distance from the Mull of Cantire, in Scotland, to the N.E. point of the county of Antrim, is less than fifteen miles.

into the ocean at Ballintrea near the Giants' Causeway, after a course of about 20 English miles; and the Main, which has a southerly course of nearly 30 English miles from Lough Gule into Lough Neagh near Randal's Town, and receives the waters of several tributaries. The Bann, a far more important stream, which flows through Lough Neagh, forms the boundary of this county towards the west, separating it from the county of Londonderry [see BANN]; and the Lagan, which rises in the county of Down, and has a course of nearly 40 English miles into the Belfast Lough, divides the counties of Antrim and Down.

Antrim is divided into fourteen baronies, Upper and Lower Dunluc and Carey in the north; Upper and Lower Glenarm, stretching along the east coast; westward, Kilconway, Upper and Lower Antrim, and Upper and Lower Toome; Upper and Lower Belfast, inclosing the county of the town of Carrickfergus, and Upper and Lower Massarene, occupy the south, and comprehend the most beautiful, improved, and populous parts of the county. These baronies include 74 parishes; one in the bishopric of Dromore, the rest in the bishopric of Connor, both which bishoprics are in the ecclesiastical province of Armagh.

The estates, with the exception of land held under the see of Connor, are freehold; either immediate from the crown, or held by lease from the grantees. The fee of the greater part of the county belongs to the Antrim family, and the Marquises of Hertford and Donegal. The other principal proprietors are the Countess Massarene, Lords O'Neil and Templeton, and Colonel Packenham. Agriculture is in a very backward state, the land being very generally occupied in small holdings by the farmers, who are also engaged in linen weaving. In the flat parts of the county, along the shore of the Belfast Lough, the farms rarely exceed ten acres, part of which is devoted to raising potatoes, the quantity thus appropriated being regulated by the quantity of manure, which latterly has been much increased by the use of lime; a small part to raising flax, the ability to purchase seed here guiding the occupier; and the remainder to oats, which crop is repeated two or three years; and when the land is exhausted, it is left to lie fallow, or 'turned to rest,' until, by receiving the manure saved, it is fitted for raising potatoes again; after which come the oats (sometimes wheat) or flax. Barley is frequently sown, but seldom in large quantities. Beans are grown in one or two parishes on the coast, chiefly for export to Scotland. Clover has lately come to be an object of attention; but turnips, vetches, or kale are little regarded. The small size of these farms, if such they may be termed, and the rockiness of the soil, lead to the use of spade husbandry; or if the farms are somewhat larger than ordinary, neighbours unite their horses, bullocks, or milch cows to form a team for the plough. Sometimes the 'dry cotters,' (occupiers of a house without any land,) or small occupiers, take what are termed 'corn acres,' or 'con acres,' i. e., ground hired to raise a single crop of potatoes or oats. In the northern part of the county, the tillage is even worse than that above-described. The cattle consist chiefly of milch cows belonging to the small farmers, who cannot give the price for a good heifer; they are, therefore, of an inferior breed. The gentlemen farmers have, however, been desirous of improving their stock by importation. There is, on an average, a cow to each family, without reckoning the population of the towns. Butter is the chief object of the dairy: 82,000 firkins from this county and those of Down and Armagh were, in 1827, exported from Belfast. Cheese is made also; that of Carrickfergus is much esteemed. Sheep are little attended to; very little wool is produced for sale, there being no more than is required for domestic purposes. Goats are continually seen round the cabins; they are tethered by a cord fastened to the horns, and put to graze on the tops of the banks. The dog and the pig are inmates of almost every cabin, and may be considered alike as domesticated animals. The number of pigs reared is very great. In the three winter months of 1826-7, upwards of 71,000, averaging 200 lbs. each, were sold in Belfast, fetching from 11. 12s. to 2l. 14s. per cwt. The small farmers depend on them for payment of their rents; and eight or ten are a common appendage to a small farm-yard. (*Wakefield's Account of Ireland*; and *MS. Communication from Ireland*.)

There is a coal mine at Ballycastle in this county, but the coal is of an inferior sort; and one of fossil wood or wood coal at Killymorris near Ballintoy on the same coast. English coal is imported into Belfast. Gypsum, marble,

beautiful crystal pebbles, and different sorts of ochres are also found.

The great manufacture of the county is that of linen. Flax was once grown to a considerable extent, more acres (viz., 11,000*) having been devoted to this crop in Antrim than in any other Irish county, except Armagh; but the cultivation of flax has diminished of late years. The seed is almost entirely brought from Holland. It is spun into yarn by the poor females, who are very expert in this branch of industry: yarn spun by the hand is preferred to that spun by machinery, which has been introduced for this purpose, and has caused a great reduction in the price of yarn. The weavers work on their own account, purchasing either spun yarn, or unspun, and weaving it in their own families. Some of them employ journeymen. Others have in their houses two or three looms (costing 4l. to 5l. each) which they let at about 10s. per annum. The weavers sell their fabrics to the bleachers, by whom they are finished, and generally sent to Dublin or London. Some are exported to England unbleached, in order to be completed there. The linens made in the county of Antrim are narrow, not exceeding when bleached thirty-two inches; those of the width of three quarters of a yard are all made here, for certain widths are peculiar to certain districts. In the neighbourhood of Belfast and Lisburne fine yard-wide linens or cambrics, lawns and diapers, are made; and at the latter town is also a manufactory of damasks. The linen manufacture, however it may have enriched the middling classes, has by no means raised the condition of the actual manufacturer, whose earnings are commonly below those of an agricultural labourer, so that many have left the loom to go to field labour. The cotton manufacture has flourished considerably in and around Belfast, and affords to the working man far greater advantages. It was introduced by Messrs. Joy and M'Cabe, in 1777, and is not carried on by the weavers on their own account, like the linen, but by men of large capital, for whom the weaver works either at his own house or in a factory. The goods manufactured are muslins, calicoes, wrappings, thicksets, corduroys, and velveteens. The number of persons employed in Belfast, Lisburne, Carrickfergus, and the neighbouring districts, is estimated at 26,000, having about doubled since 1800. To the introduction of the cotton manufacture, and to the commercial importance of Belfast, may be ascribed the improvement observable in the condition of the people who live in the neighbourhood of that town; in which are concentrated nearly all the other manufactures carried on in this county, as well as most of the foreign commerce. [See BELFAST.] There are some salmon fisheries at Custendal, Tor Point near Fairhead, Ballycastle, Carrick-a-rede, and the Bush-foot. The more important one in the Bann near Coleraine rather belongs to the county of Londonderry. Belfast is supplied with oysters and other fish from Carrickfergus.

The population of the county in 1831 (the last census taken) was 323,306: in 1790, Dr. Beaufort (*Memoir of a Map of Ireland*) estimated the inhabitants at 160,000. According to the returns of the Commissioners of Education in 1824-26, the number of children receiving education in schools was 20,050, of whom 11,800 were boys and 8250 girls: 3865 were of the established church, 11,640 were presbyterians, 430 dissenters of other denominations, 3785 Roman Catholics, and of 330 the religious profession could not be ascertained. The shire town is Carrickfergus, once the first sea-port in the north of Ireland, and then defended by a strong castle, where a small garrison is still kept. The population of the county of the town of Carrickfergus was, in 1831, 8698. Belfast is, however, the place of greatest importance (population 53,287). Both of these are on the north shore of Belfast Lough. Lisburne, on the river Lagan, has a population of 5218; and Antrim, near Lough Neagh, of 2655. [See the Articles on those places.]

The other towns are Larne, on a lough or inlet of the same name, on the east coast, (population 1551,) an inconsiderable place with a poor harbour: Ballymena, (population 4063,) and Ballymony, (population 2222,) a neat little town, with stone houses, and slated roofs, and having a decent inn; (both these are on the road from Antrim to Coleraine;) Ballycastle, (population 1683,) with its coal mine, on the north coast; and Randal's Town, a little to the N.W. of Antrim, and near the shore of Lough Neagh. The

* This return refers to the year 1809, and does not seem to include patches of less than one acre, which are very numerous. It is probable that the acre is the Irish acre, which is equal to more than an English acre and a half.

other places called towns in the population returns have under 700 inhabitants, and are not worth mentioning, except Connor, which contains the ruins of a cathedral, and gives name to the diocese.

The chief antiquities are the above-mentioned cathedral; the round tower at Antrim [see ANTRIM TOWN]; the remains of two other towers, one at Armoyn near Ballycastle, and the other on Ram Island in Lough Neagh; Dunluce Castle, on the coast, not far from the Giants' Causeway; and the ruins of a castle on Rathlin island, which is said to have given shelter to Robert Bruce when driven from his native land. A cromlech and a rocking stone are to be seen in island Magee near Larne.

The county returns two members to parliament; Belfast two; Carrickfergus and Lisburne each one. The number of electors for the county under the Reform Bill of 1832 amounted to 3487, of whom 561 were 50*l.* freeholders; 462 were 20*l.*, and 2209 were 10*l.* Of these 3026 voted at the last general election (of 1832). Antrim gives the title of Earl to the family of Macdonnell. (*Wakefield's Account of Ireland*; *Beaufort's Memoir of a Map of Ireland*; and *MS. Communication from Ireland*.)

ANTRIM, a town in Ireland, in the county of the same name, about 105 miles north of Dublin, and about 15 miles N.W. from Belfast. 54° 43' N. lat., 6° 6' W. long. of Greenwich. It is near the N.E. extremity of Lough Neagh, the largest lake in Ireland, and on the Six-mile Water, a small stream which flows into the Lough. Although Antrim gives name to the county, it is not the shire town, and had, in 1831, a population of only 2655. It was once, however, a place of great consequence, as appears from its having, before the Union, returned two members to the Irish House of Commons, from the mayor being admiral of a considerable extent of coast, and from the corporation having been entitled to the customs paid by all vessels within the limit of the jurisdiction thus enjoyed by the mayor. This grant was repurchased by the crown, and the custom-house was transferred to Belfast. Antrim consists of one long street, with the market-house in the middle. The parish church is a modern Gothic structure, with a steeple and spire. and there are a Catholic chapel and several dissenting meeting-houses. The linen manufacture furnishes employment to many of the inhabitants. In the neighbourhood are Shane Castle, the ancient seat of the O'Neils; and Antrim Castle, once the seat of the Skeffingtons, Viscounts and Earls of Massarene, and now of Skeffington Foster, Earl of Ferrard. The living is a vicarage in the diocese of Connor.

At Antrim is one of the ancient round towers found in many parts of Ireland: it is perfect, and is 95 feet high. The origin of these towers has been keenly disputed by antiquarians; most of them, however, agreeing that they are the work of the Ostmen or Danes. Mr. Ledwich (*Antiquities of Ireland*) supposes them to have been the belfries of ancient churches. Other opinions have been broached of late, and by some people received.

This town was the scene of one of the severe contests which occurred during the unhappy civil disturbances in the year 1798; in it Viscount O'Neil, father of the present Earl O'Neil, received a mortal wound. The insurgents were entirely defeated.

ANTWERP, called by the natives Antwerpen, by the Spaniards Amberes, and by the French Anvers, is situated on low ground on the right bank of the Schelde, where the river makes a considerable bend, in 51° 14' N. lat., and 4° 22' E. long. It is about 25 miles in a straight line, nearly due north of Brussels, the capital of Belgium, about 9 miles above Fort Lillo, and 45 miles reckoning to Flushing, at the mouth of the Schelde, where vessels bound to Antwerp must take a Dutch pilot as far as Lillo. The average breadth of the river opposite to the city is about 440 yards, and the ordinary rise of the tide is stated at 10 feet. For the two miles in front of the city of Antwerp the depth at low water is from 32 to 42½ English feet.

Antwerp is a strongly fortified city on the land side, and has, in addition, a large citadel on the south, built by the Duke of Alba in 1568. The houses are generally of a sandstone called *kareelsteen*, brought from Boom, a few miles south of Antwerp. This still magnificent, and once still richer and flourishing town, has 26 public places, 70 public buildings, and 162 streets, or, according to other accounts, 212. The great glory of Antwerp is its cathedral, the finest building in the Low Countries; it is said to be 500 feet long,

240 wide, and has a spire of stone, generally said to be above 400 feet high. But accounts differ as to the exact height of this steeple, some making it as much as 451 feet, and even more of the two spires originally designed, only one is finished. By the kindness of a friend, we are enabled to rectify the height of the spire of Antwerp cathedral, which must be reduced to 366 feet at the outside; consequently it is lower than the spire of Salisbury cathedral, if the height of this English spire can be depended on. The observations on the height of Antwerp spire were made with a mountain-barometer by Jones, and were repeated in order to insure accuracy. Being warned by this example, we will not undertake to vouch for the accuracy of the other dimensions of the cathedral. With a small telescope, objects may be seen pretty clearly from the spire of the cathedral for 40 miles round. The interior is adorned with two of Rubens' finest pictures, one of which, the Descent from the Cross, is almost unrivalled in its masterly grouping. The Hotel de Ville, or Town House, is a large and handsome building, with a front of about 260 feet; and the Bourse, or Exchange, which rests on marble pillars, was the finest building of the kind in Europe, and is said to be the model on which those of London and Amsterdam were built. St. James's church, which contains the tomb of Rubens, a native of the city, the church of St. Michael, the hall of the Hanse Towns, and the imperial palace, built by Napoleon, in the *Meer*, which is the chief public place, are also fine edifices. The new quay and the great basin of Antwerp were begun by Buonaparte, when he intended to make this city one of his strong naval stations. The area of the great basin is 17.16 English acres, and of the small one, seven. On each side of the great basin are two careening docks, made during the empire of Napoleon for repairing the ships of war constructed here. The new custom-house is at the head of the great basin. Along the whole line of the new quay a row of elms has been planted, for the purpose of ornament and to form a pleasant walk in the heat of summer. In such modes of decorating their chief streets and the environs of their towns, the people of the continent are much superior to ourselves.

Antwerp contains a great military arsenal, dock-yards, and an extensive rope-walk. The citadel is a regular pentagon, surrounded by a wet ditch 90 feet broad: it has five bastions, each containing a casemate capable of holding 400 men. Some years ago it contained the great prison for felons, where (in 1817) about 1000 were in confinement for various periods, none for less than five years, for various offences. They were kept hard at work, but their employments are described as sedentary, and some of the apartments as ill ventilated and disagreeable.

Travellers cannot fail to be struck with some appendages of Catholicism to be seen in the streets of Antwerp. Pious individuals erect, at their own expense, a Madonna with the child Jesus at the corner of the streets, the former exhibited in glaring colours, and the latter with a gilded glory round his head. Napoleon swept away these testimonials of superstition, in which he perhaps showed less policy than the Protestant king of the Netherlands, who restored them.

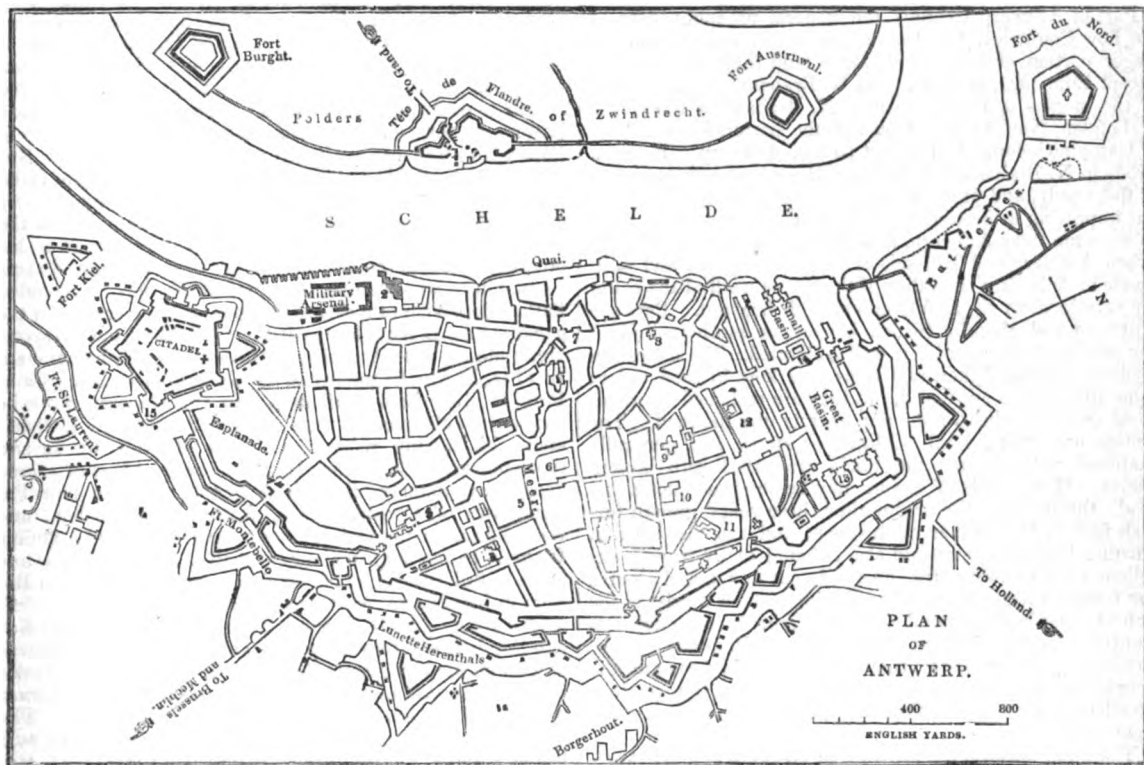

Antwerp, which was the birth-place of Jordæns, Rubens, Vandyke, the Teniers, and of Quintin Masseys, who, as the story goes, was changed by love from a blacksmith into a painter, still possesses many memorials of these illustrious artists in several good collections of paintings. The geographer Abraham Ortelius was a native of Antwerp. It has also an Athenæum, a botanical garden, public library, and an academy of the fine arts.

The commerce of Antwerp is still considerable, though far below what it was in the fifteenth and sixteenth centuries, when at one period it had a population of 200,000, and 2000 vessels annually entered its port. Its population in 1831, according to Dutch authorities, was only 77,199: 995 ships entered its port in 1829; 690 in 1830; and 362 in 1831. A corresponding decrease took place in the number of vessels that cleared out of Antwerp from 1829 to 1831 inclusive. As to its inland trade, Antwerp is connected by canals with Mechlin, Louvain, Brussels, and with Ghent by the Schelde. Its chief fabrics are thread, tape, linen cloth, silks, sugar-refining, calico-printing, and damask cutting. They use the French coinage at Antwerp, and also the French weights and measures. There is a bank, which is a branch of the Brussels bank. Antwerp exports flax and bark to Great Britain; and madder, refined sugar, and Belgian manufactured articles to other places.

The language which is most in use among the higher classes of Antwerp is the French, but the Flemish is the true language of the country and of the majority of the people.

We are not able to assign the period when Antwerp became a town; the Ambivareti of Cæsar, which is probably a corrupted name, did not live on the Schelde, as Malte Brun, without the smallest reason, supposes. Antwerp, in the eleventh century, was a small republic. The industry of its inhabitants, joined to its favourable situation, raised it to the rank of the first commercial city of Europe, during the reign of Charles V. But during the reign of his un-

worthy successor it suffered among the horrors of Alba's government, and the stormy times that followed the declaration of independence at Antwerp in 1580. In 1576 it was pillaged for three entire days by the Spaniards. The siege of Antwerp, by the Prince of Parma, and its reduction in 1585 after a fourteen months' siege, form an epoch in the history of the city. By the terms of the peace of Westphalia in 1648, the navigation of the Schelde was closed, and this, added to other calamities, destroyed the prosperity of the city. The navigation of the Schelde was opened at the time of the French occupation of Antwerp, which took place in 1792. In 1793 the French evacuated

it, but took it again in 1794, when it became the capital of the department of Deux Nèthes. It was surrendered to the allies after the treaty of Paris in 1814 by Carnot, who had defended it up to this time. The city suffered after the revolution of 1830 from the cannonading which the Hollanders in the citadel directed against the town.

The last memorable event in the history of Antwerp is the capture of the citadel by the French, under Marshal Gerard. The King of Holland having refused to evacuate the citadel of Antwerp, conformably to the terms agreed on by the high contracting powers, who arranged the separation of Holland and Belgium, the French entered Belgium on Nov. 15, 1832, with about 70,000 men, a large part of whom were merely intended to occupy the country round Antwerp. The citadel was defended by General Chassé, for the King of Holland, with 4500 men. The French broke ground on the night of the 29th of November; on the 14th of December, they made a breach in the face of the Fort St. Laurent by establishing three mines in it, and immediately took the place by assault. The French then directed their breaching battery against the Toledo bastion, on which they soon made considerable impression. On the 24th the citadel surrendered, and the garrison became prisoners of war. The defence of General Chassé was neither vigorous nor well concerted, though his artillery was well served; and the only result of the obstinacy of the King of Holland was the loss of much life, and the infliction of much human suffering. The loss of the French, according to official reports, was 108 killed, and 695 wounded. The loss of the Dutch, in killed, wounded, and missing, was between 500 and 600. (See *Journal of an Horticultural Tour, &c., Edinburgh, 1823*; *Journal of an Excursion to Antwerp, London, 1833, &c.*)

ANTWERP, one of the eight provinces of the kingdom of Belgium, is bounded on the north by N. Brabant, by Limbourg on the East, on the south by S. Brabant, and on the west by east Flanders and part of Zeeland. The Schelde separates Antwerp from East Flanders. Its area is about 1105 E. square miles, and the population (1829), 343,214. The following table exhibits the progress of population in the province of Antwerp for the ten years.

From 1803 to 1812

No. of Births.	Marriages.	Divorces.	Deaths.	Increase of Population.
96,058	21,579	13	87,126	8932

and, from 1815 to 1824,

101,471	23,075	2	70,623	30,848
---------	--------	---	--------	--------

The following statistical facts are from the tables of Vander Maelen (*Etablissement Géographique de Bruxelles, fondé par Ph. Vander Maelen en 1830*).

He makes the whole superficies of the province about 1097 English square miles, being eight less than our estimate: the uncultivated land is rather more than one fourth of the whole surface; the surface occupied by water (which is not included under the head of uncultivated land) is nearly $\frac{1}{10}$ of the whole.

Population in 1831.

City.	Country.	Total.
122,370	225,220	347,590

Education.

Children in communal schools.		Children in private schools.		Total.
Male.	Female.	Male.	Female.	
11,617	8,557	3,488	3,244	26,906

Therefore one in every thirteen inhabitants is in the schools, nearly.

Antwerp sends to the chambers at Brussels four senators and nine representatives; the province has one archbishop.

The province of Antwerp is very level. The only river is the Schelde, which receives on the right bank the Rupel at Rupelmonde: the Rupel is formed by the union of the greater and smaller Nethe, the Dyle on which Mechlin stands, and the Senne which runs by Brussels. As this region belongs to the great delta of the Rhine, it partakes of the general character of that extensive level: the soil contains a great proportion of sand, with no stones in the flat districts. The rain water penetrates the surface of the earth and is found in the low parts at about ten feet depth, and often much less.

Part of Antwerp exhibits the general productiveness of the Low Countries, but this province contains, perhaps, a larger portion of heath and barren land than any of them except Limbourg, or we may say N. Brabant, as a great part of the morass of Peel is given to N. Brabant by the treaty of London, Nov. 1831. A part of the barren Kempenland or Campine belongs to the east part of Antwerp. Between Breda in N. Brabant and Antwerp the country is described as flat, sandy, and poor, and in part incapable of cultivation, but improving somewhat as we approach to the latter city: as we come near Antwerp, it is pretty well cultivated. Between Antwerp and Brussels it is generally rich and well-wooded: following the valley of the Senne we find the country very level as far as Vilvorden in S. Brabant. Between Antwerp and Mechlin (which is near the southern limit of the province) the country is well cultivated. The inclosures made by ditches, dykes, and trees, are kept in good order: some live hedges are found, but they are reckoned injurious. Good crops of wheat, rape, and carrots line the road. The houses are strong built of brick or stone, and generally thatched with straw: the roads are paved with broken stones. Many fields of broom may be observed along this road: the stems of the broom after three years' growth furnish fuel for the kitchen or the oven, and are also used in burning bricks; the ground also is found to be in very excellent condition after the broom is cut down, and secures the farmer a heavy crop. The Polders, which consist of the richest grass lands, extend along the Schelde as far down as Zantvliet, and to Bergen-op-Zoom in N. Brabant. These Polders, which are lower than the level of the sea and the Schelde at high water, are protected by dykes: they produce excellent crops almost without any other manure than ashes from wood.

The chief towns of the province of Antwerp are, Antwerp, Mechlin, Lier, Turnhout, Gheel, and Boom. The language of the mass of the people is Flemish, though French is spoken by the educated classes in the towns. From the peace of Baden, 1714, the county and quarter of Antwerp, as the district was termed, (see Busching's *Geography*,) belonged to the House of Austria, and formed a part of the Austrian share in the Duchy of Brabant. After the French revolution it was united to France, and formed the department of Deux-Nèthes. In 1814 it became a part of the United Kingdom of the Netherlands; and in 1830 it became a province of the new kingdom of Belgium.

ANUBIS, an Egyptian deity, represented with the head of a fox, dog, or jackal, and a human body. In some Egyptian remains we observe him standing by a bier, on which a mummy is lying. Anubis was the son of Osiris and Nephthys, the wife of Typhon, and sister of Osiris. He appears to have been considered in one sense as the conductor and guardian of departed souls, and in this respect his functions bear some resemblance to those of Hermes of the Greeks, and Mercurius of the Romans. Other resemblances are suggested between this Egyptian deity and Hermes, (the god with the golden wand, χρυσόραβος,) by the supposition that the element *Anub*, in Anubis, has the same signification as the Coptic *noub*, (see Coptic version, Matt. ii. 11,) signifying gold. (See Jablonsky's *Pantheon*, *Anubis*.) For the phonetic name of Anubis as son of Isis, see Salt's *Essay*, &c., pl. iii.)

ANVILLE, (JEAN BAPTISTE BOURGUIGNON D.) a distinguished geographer of the eighteenth century, was born at Paris in 1697. From his boyhood he showed a strong bias for geographical studies. At twelve years of age, while at college, a map which fell by chance into his hands, for maps were not then so common as they are now, determined his pursuits. He began alone and without assistance to draw maps of the countries mentioned in the Latin classics which he was then studying. For this pursuit he sometimes neg-

lected his regular tasks, and he was once caught in his favourite employment by the professor of his class, who, however, perceiving on the rough sketch before him evident signs of the genius of his pupil, encouraged instead of punishing him. The study of ancient geography continued ever after to be the object of his special predilection. After leaving college, he became acquainted with several learned men of his time, and particularly with the Abbé de Longuerue, a laborious investigator of antiquities, at whose request he set about drawing several maps of France and its various provinces, for the Abbé's work; *Description géographique et historique de la France ancienne et moderne*. At the age of twenty-two, he was appointed one of the King's geographers. Soon after, his map of the kingdom of Aragon was published by desire of the Duke of Orleans, Regent of France, and against D'Anville's judgment, who did not consider it as sufficiently accurate. He was employed by the Jesuits to make an atlas of China for the edition of Duhalde's *History* of that empire. This Atlas (*Nouvel Atlas de la Chine*, &c.) was also published at the Hague in 1737. But the work that established his reputation, was his map of Italy, which he published in 1743. He constructed this map chiefly upon a close investigation of the ancient writers, and of the Roman itineraries; he corrected many gross errors of his predecessors, and the accuracy of his work was proved some years after, when Pope Benedict XIV. having enabled Father Bosovich to measure a degree of the meridian in the papal states, D'Anville's positions were found to correspond pretty closely with the observations of the mathematician. In 1744, D'Anville published his *Geographical Analysis of Italy*, in illustration of his map. In this elaborate work he shows the difference between his and Sanson and Delisle's maps, he having reduced the area of Italy by several thousand square leagues. He drew several maps of sacred geography, namely, *Ecclesia Africana*, and the four Patriarchates of Constantinople, Antiochia, Jerusalem, and Alexandria, for the *Oriens Christianus* of Father Le Quien. It would be too long to enumerate all D'Anville's works and maps, a full catalogue of which is given by Barbié du Bocage in his *Notice des Ouvrages de M. D'Anville précédée de son Eloge par M. Dacier*, Paris, 1802. He published one hundred and four maps on ancient, and one hundred and six on modern geography. He wrote about forty works, including several memoirs, which are inserted in the *Recueil de l'Académie des Inscriptions et Belles Lettres*. The following are the most important among his works, all published at Paris, *Analyse géographique de l'Italie*, 1744, 4to., already mentioned; *Dissertation sur l'Etendue de l'ancienne Jérusalem*, 1747, 8vo.; *Mémoire sur la Carte des Côtes de la Grèce*, 1751, 4to.; *Notice de l'ancienne Gaule, tirée des Monumens Romains*, 4to., 1760; a work much and deservedly esteemed, in which the author, however, confines himself to Gaul as was under the Roman empire. To this must be added: *Eclaircissements géographiques sur l'ancienne Gaule*, 1743, 12mo.; *Mémoire sur l'Égypte ancienne et moderne, suivi d'une Description du Golfe Arabique*, 1766, 4to. Mr. Ripault, one of the scientific men who accompanied Bonaparte's expedition to Egypt, says that they were struck with the accuracy of D'Anville's positions. Indeed when we look at D'Anville's map of Egypt, and consider what his materials were for constructing it, we readily admit that it is a most convincing proof of his great industry and acuteness. The navigator Bougainville, also gave a similar testimony in favour of D'Anville's map of Asia, especially with regard to the Molucca islands, and the coast of New Guinea. — *Géographie ancienne abrégée*, 1768, 3 vols. 12mo., and 1769, fol., translated into English under the title of *Compendium of Ancient Geography*, London, 1791, 2 vols. 8vo.: *Traité des Mesures itinéraires anciennes et modernes*, 1769, 8vo., a most valuable work, in which he estimates and compares the itinerary measures which have been in use in various ages, among the nations of Europe and Asia, and ascertains the variations which each had undergone in the course of time; *États formés en Europe après la Chute de l'Empire Romain en Occident* 1771, 4to.; a useful book for the history of what are termed 'the dark ages,' from the fifth to the twelfth centuries, and forming a link between ancient and modern geography; *L'Empire de Russie considéré dans son origine et ses accroissemens*, 1772, 12mo.; *L'Empire Turc considéré dans son établissement et ses accroissemens*, 1772, 12mo. With regard to the geography of Turkey, D'Anville seems to have been fully sensible of the difficulties of the subject, owing to the want of observations, for he

used to say that people in his time 'were better acquainted with the geography of India and China, than with that of the kingdom of Philip and Alexander,' meaning Macedonia; and, in fact, he has himself fallen into considerable errors in his map of that country, as M. Cousinery has shown in his *Voyage dans la Macédoine*. [See AMPHIPOLIS.]

A similar remark will apply to his map of Asia Minor, to the neck or isthmus of which he assigned a breadth from north to south which was less than the truth by one whole degree: this fundamental error necessarily deranged many of his positions, especially in the eastern part of that peninsula. D'Anville's map of the Tigris and Euphrates is still, in some points, the authority on which our present delineations are partly founded; in other, and some important points, he has long since been corrected; but so ignorant are we still of the true course of some of the streams that enter the head of the Persian Gulf, east of the Tigris, that we cannot yet positively say whether D'Anville is right or wrong. In order justly to estimate the merit of D'Anville's exertions, we ought to bear in mind, that in his time geographical information was much more scanty than at present; that comparatively few points of the earth had been determined by astronomical observations; that the surveys of coasts were very imperfect; and that he had, in consequence, but few guides whom he could trust. D'Anville himself had never travelled beyond a hundred miles from Paris; but he made up in a great measure for these disadvantages by his indefatigable researches in the authors of antiquity, as well as of the middle ages, who could afford any information on geographical matters, and by a rare sagacity and judgment in eliciting truth out of conflicting statements and opinions. He was greatly assisted by his wonderful memory. Geography made under him rapid strides towards accuracy; he used himself to say, for he was somewhat of an egotist, that 'he had found a geography made of bricks, and left one of gold.' (See his 'Eloge,' by Dacier, already mentioned.) The maps of D'Anville have been continually reproduced in England in various forms; and errors, which the author could not possibly avoid, often still appear in our ordinary maps.

But it was only on the subject of his favourite science that he showed any vanity; in all other matters he was simple and unassuming. He lived more in the past than in the present, more with books than with men. It is remarked by the biographer of D'Anville, (*Biog. Universelle*, D'Anville,) that his style is not good, and that owing to this and other causes there is often a want of method and clearness in his dissertations. In this opinion we entirely concur: his language sometimes is very inelegant and not very correct, and his discussion of the position of a place would sometimes hardly lead us to expect the precision which we find in his maps. We believe that D'Anville was occasionally more indebted to previous geographers than is generally supposed; in saying this, we do not mean to detract from his real merit, which will stand the test of the most rigorous examination. In 1773 the French Academy of Sciences elected him, then seventy-six years of age, into their body, and the same year he succeeded to the vacant place of first geographer to the king. In 1777 he published his *Considérations sur l'Etude et les Connoissances que demande la composition des Ouvrages Géographiques*, a sort of legacy for those who should follow him in the same career. In 1779 Louis XVI. purchased his valuable collection of maps, which he had collected in the course of sixty years devoted to science. D'Anville's constitution, naturally delicate, became now exhausted, his sight failed, and he at last fell into a state of physical and mental imbecility, from which death relieved him in 1782, at the age of eighty-five. His wife, with whom he had passed fifty-one years of his life, died the year before, without his being sensible of her loss. He left only two daughters. There are two more works translated or compiled in English from D'Anville, besides the 'Compendium' already mentioned, namely *A Complete Body of Antient Geography*, including the *Orbis Romanus*, *Orbis Veteribus Notus*, of D'Anville, with additions, London, 1775, and the *Geography of the Greeks and the Romans in the time of Alexander and Augustus*, London, 1816.

ANWARI, or ENWERI, properly AWHAD-ED-DIN ANWARI, a celebrated Persian poet, who flourished in the twelfth century of our æra. He was born at Bedna, a village in the district of Abjurd, in Khorasan: the immediate neighbourhood of his place of birth bears the name of Khaweran, whence Anwari is also sometimes surnamed

Khawerani. He received his education in the college of Mansur, at Tus. A visit of the Seljukide sultan Sanjar to Tus furnished him the first opportunity of making himself known by a poem in praise of the sultan, which is by oriental critics considered one of his best productions. Sanjar, who was fond of poetry, enlisted him among his suite, and bestowed honours and ample rewards upon him. Anwari followed the sultan to Merw, then the residence of the Seljukides. Here the poet devoted himself to astrology, but was not fortunate in his predictions, by one of which he made himself so ridiculous that he retired from Merw to Balkh, where he died in the year 597 of the Hegira, (A.D. 1200-1201.) Manuscript copies of the *Diwan*, or collection of poems of Anwari, are not unfrequently met with. It consists chiefly of *kasidas*, or long poems, mostly panegyric; and of *ghazels*, or shorter lyrical effusions. In the East, the *kasidas* of Anwari are admired in preference to his *ghazels*: to our own taste, the latter are more agreeable; in them the style of Anwari is simple and comparatively easy, while his *kasidas* abound in metaphors and conceited historical allusions, which render many of them unintelligible without the aid of a commentary. It deserves to be remarked, that the language of Anwari, though he is one of the earlier Persian poets, is as full of Arabic expressions as that of almost any subsequent writer; whereas, in the *Shahnameh* of Firdusi, who lived only little more than a hundred and fifty years before Anwari, we find the Persian in a state of unadulterated purity. It is unlikely that the spoken language should have undergone so striking a change within so short a period; and we are inclined to think that Firdusi, to preserve the national character of his poem on antient Persian history, studiously avoided all Arabic expressions which might, at his time, have crept into the Persian language.

ANWEILER, a town in the former duchy of Deux Ponts, and now in the circle of the Rhine, forming part of the kingdom of Bavaria; it is built on the Queich, six miles distant from Landau, and has 2200 inhabitants, who subsist chiefly from the profits of their paper-mills. The ruins of the castle of Trifels, where Richard, Cœur-de-Lion, was kept a prisoner in the year 1193, may be seen in the vicinity of this place.

ANXUR. [See TERRACINA.]

ANYTUS. [See SOCRATES.]

ANZIN, a village in the immediate neighbourhood of Valenciennes (department of Nord) and the seat of the most extensive collieries in France. The coal was discovered in 1734, by the Viscount Desaudrouin. The working of these mines is thought to have been attended with greater difficulties than of any other in Europe. The pits amount to forty all together, and sixteen of these are of great depth; some are as much as 300 metres, or nearly 1000 feet; and some authorities (*Dict. Géog. de la France*) extend them to 389 metres, or nearly 1300 feet. The coal burns fiercely, and is in demand for purposes which require an intense flame; and it is perhaps to this circumstance that we may ascribe the establishment of some glass houses and manufactories at Anzin. The number of persons employed in the mines amounts to 16,000, and the annual produce is about 4,000,000 of quintals (of 108 lbs. avoirdupois). Comparing the above statements with those given in the *Dictionnaire Géographique de la France*, (1804,) it appears that the working of these mines has prodigiously increased; for at the last mentioned period only 1500 workmen were employed. The population of the village was then 3096; it is now about 4000. (Malte Brun; Balbi; *Dict. Geog. de la France*.)

ANZUAN, commonly called Johanna, but more properly Hinzuan, the name given to it by the inhabitants, is one of that cluster of islands which are situated in the channel of Mozambique, nearly at an equal distance from the continent of Africa and the island of Madagascar, and which are known by the name of the Comoro Islands. Though not the largest of these islands, being smaller than Comoro, Anzuan is the most important, from having the best anchoring-ground, on which account, before the acquisition of the Cape, it was much more frequently visited by English vessels trading to the East Indies and China, than has lately been the case.

This island is of a triangular form. The most southern point lies in 12° 25' S. lat., and the most eastern in 44° 34' E. long., and to the north it extends nearly to the 12th southern parallel. Its circumference is estimated at from seventy to eighty miles; as to area it may be compared to the island of Madeira, which it resembles in many other points.

The shore rises in many parts with remarkable boldness;

and is broken by a few open bays. Rooky reefs extend from its extremities far into the sea; and from the south-western to the north-western point it is bounded by a reef which is two miles from the shore in many places. The interior of the island presents a succession of mountains and valleys. The mountains are of volcanic origin and some of them rise to a considerable height, probably to 6000 feet and upwards; among the highest is that called the Peak, which is rather of an oblong form and situated near the eastern extremity of the island. With the exception of the highest summits, which present barren rocks, the mountains are covered with trees, chiefly fruit-trees and palm-trees. The valleys are rather narrow, but they contain in some places much level ground which is partly cultivated, and partly planted with trees. The continually changing variety of the landscape offers many highly picturesque views, and Sir William Jones does not hesitate to give them the preference over the finest views in Switzerland and Wales.

Though exact observations are wanting, the climate appears to be mild, the heat at least not being oppressive even in July.

Rice is raised, but not in large quantities. A kind of vetch is much more cultivated, and forms the principal food of the inhabitants. Yams, papayas, and sweet potatoes, abound in the kitchen-gardens. The fruits consist principally of cocoa-nuts, limes, oranges, wild pine-apples, and plantains. The areca-palms are numerous, as well as the shrubs that yield henna; the fruits of the former and the leaves of the latter are used here as in India.

Not a horse is to be found on the island, and persons of rank travel in rudely constructed palankins. Cattle are numerous and excellent, but rather small, weighing only from 300 to 350 lbs. each. Goats abound, and a wild species inhabits the most rugged eminences. Poultry is very common, and of the Guinea-fowls thousands may be seen in a wild state. No snakes, nor other venomous reptiles exist in this island; the only annoyance of the inhabitants is the mosquitos. Fish abounds everywhere along the shore. White whales frequently visit the channel of Mozambique, and are often killed by the inhabitants of this island. Cowries are found on the shoals in the neighbourhood, and form an article of export.

The population consists of Africans and Arabs. The latter, who compose the upper classes, have introduced their religion, laws, and a part of their knowledge, especially of navigation. But the Africans, who compose the bulk of the population, are very ignorant, and very little advanced in civilization. The government is a monarchy limited by an aristocracy. The king has no power of making war by his own authority; but if the assembly of nobles, who are from time to time convened by him, resolve on a war with any of the neighbouring islands, they defray the charges of it by voluntary contributions; in return for which they claim as their own all the booty and captives. As the succession to the title and authority of sultan is not fixed by unalterable laws, but requires the confirmation of the chiefs of the island, it gives rise to factions, and occasions frequent civil wars, which, together with the depredations of pirates from Madagascar, have lately much reduced the number of inhabitants, who formerly were estimated at about 100,000.

The town of Matsamudo, which lies at the end of an open bay, is visited by European vessels for refreshment, and is populous. But the king resides in another town, called Domoni, which is ten miles from Matsamudo, in the interior of the island. The trade of this island is very inconsiderable. It sends nothing to the markets of Europe, but has some intercourse with the island of Madagascar, the coast of Mozambique, and the other Comoro islands: it exports the merchandise received from the Europeans returning from Bombay, which it exchanges for elephants' teeth, rice, cattle, and other productions. (Sir William Jones; Capt. Williamson; and Horsburg's *Directory for Vessels sailing to and from India*.)

AORTA, a Greek word (*ἀορτή*). The aorta is the great vessel from which all the arteries of the body which carry red blood derive their origin. It arises from the upper and back part of the left ventricle of the heart. Its origin is directly opposite the lower margin of the cartilage of the third rib on the right side of the chest. From this point it ascends behind the pulmonary artery, still inclining a little to the right side of the chest. It continues to ascend as far as the top of the second vertebra of the back. All this part

of the vessel is called the *aorta ascendens*. When it reaches as high as the lower margin of the first rib, it bends obliquely backwards towards the body of the third vertebra of the back. This part of the vessel is called the *curvature*, or the transverse *arch* of the aorta. From the third vertebra of the back, where its arch terminates, it proceeds in a straight course downwards through the chest, immediately in front of the spinal column, and towards the left side of it. Through an opening formed for it in the diaphragm, (see *DIAPHRAGM*), it passes from the chest into the abdomen. All this part of the vessel, namely, that extending between the termination of the arch and the diaphragm is denominated the *descending* or the *straight* portion of the thoracic aorta. Having passed through the diaphragm into the abdomen, it is called the abdominal aorta; it continues to descend along the front of the spine a little obliquely, until it reaches the fourth vertebra of the loins: here it divides into two branches of equal size, and may be said to terminate, for it now loses the name of aorta; the two great branches into which it divides being denominated the *common iliac arteries*.

The first two branches which are given off by the aorta are those which supply the heart itself. The great branches which spring from the arch of the aorta are principally distributed to the chest, head, and upper extremities. The branches which arise from the descending or the straight portion of the thoracic aorta are likewise distributed to the viscera of the thorax, those which supply the lungs being called the *bronchial arteries*. The branches which are given off from the abdominal portion of the aorta supply, for the most part, the viscera of the abdomen; and the iliac arteries are distributed principally to the viscera of the pelvis and to the lower extremities.

The structure of the aorta does not differ materially from that of arteries in general (see *ARTERY*). At its origin, in the left ventricle of the heart, are placed three valves of a semilunar or crescent shape, termed the semilunar valves, (see *HEART*), which effectually prevent a reflux current of blood from the vessel into the heart.

The aorta is subject to numerous and important diseases, as inflammation, aneurism, ossification, &c. [See *CARDITAS*, *ANEURISM*, *OSSIFICATION*, &c.]

AOSTA, the duchy of, one of the five divisions of Piedmont, or rather, speaking more accurately and according to the present administrative system of that country, one of 'the eight divisions of the continental states of the King of Sardinia.' It consists chiefly of one long valley of the same name, which follows the course of the Dora Baltea. This river, from its source in the Graian Alps, runs first eastwards for about thirty-five miles, and then turns abruptly southwards below Chatillon, flowing in the same direction to the village of St. Martin, where it enters the province of Ivrea, on its way to the Po. Many smaller valleys open into the main one on both sides, following the course of the mountain streams which flow from the Upper Alps into the Dora. The principal are on the north side, the Val Lesa, which begins at St. Martin on the Dora and extends up to the glacier of Lys, at the foot of Mont Rosa; Val Challenet, called also Val d'Ayas, beginning at the town of Verrez, the Vitricium of the Romans, and stretching likewise northwards to the glaciers of the same range: Val Tournanche, which begins at Chatillon and runs to the foot of Mont Cervin, to the eastward of which is a pass, called the Joch, perhaps the highest in Europe, and leading to Visp in the Valais; Val Pellina, which extends north-east to the city of Aosta, along the base of Mont Velan and Mont Combin to the Col d'Oren, over which there is another pass nearly 8000 feet high, into the Valais; the Val de Buthier, so called from the torrent of that name, which leads from Aosta to the Great St. Bernard. Ascending the Dora from the city of Aosta towards the foot of Mont Blanc, the main valley branches out into several high and narrow gorges: of these the Val d'Entrevres contains the village and the baths of Cormayeur, from whence a pass leads northwards over the Col de Ferret into the Valais; and the Val Verc called also Allée Blanche, skirts several vast glaciers that descend from the range of Mont Blanc, and leads to the Col de la Seigne, over which there is a pass into Savoy. Here the Dora has its source in the little lake Combal. Another stream, coming from the south-west, joins it at Pré St. Didier, a village with mineral waters. The valley that follows this stream, and leads to the pass of the Little St. Bernard, is called Val de la Tuile. This is the best and the easiest of all the passes leading from the Val d'Aosta over

the Alps. A lofty summit, called the Cramont, covered with perpetual snow, divides the Val de la Tuile from the Allée Blanche. The other valleys that branch out of the main one south of the Dora are: Val Grisanche, which leads from the village of Livrogne to the great glacier of Riotour, embedded in a lofty group of Alps that projects eastward of the Graian range between the Little St. Bernard and Mont Iseran; Val Regence, called also Val di Rema, which leads in a parallel direction; Val Savera Vecchia, or Saveranche, leading from Villeneuve, on the southern bank of the Dora, to the foot of Mont Iseran; Val di Cognà, extending from Aosta to Mont Soana, an offset from the great chain of Mont Iseran, which incloses the province of Aosta on the south; a passage for mules leads over Mount Soana to the valley of the river Orca in the province of Turin; and, lastly, Val Camporcier, which stretches along the same range, and opens to the right bank of the Dora, nearly opposite St. Martin.

Each of these valleys contains villages and hamlets; several hamlets are ranged in groups on the side of the mountain, and the principal one of the group is distinguished by the parish-church. The lower parts of the valleys are very fertile; they produce little wheat, but plenty of barley, oats, and rye, all sorts of fruit, and above all, rich pastures, which feed a great number of cattle and flocks of sheep. The Val d'Aosta supplies the neighbouring province with butchers' meat, butter, and cheese. Most of the cheese, however, is made by Swiss shepherds from the Valais, who come down by the St. Bernard and buy the milk of the farmers. The peasants of Aosta are industrious; most of them are possessed of some land, and those of the upper valleys, who are the poorest, emigrate for the winter, and earn their bread by various callings in the neighbouring countries, from which they return in summer for the labours of their scanty fields. Some have mules, and act as carriers or guides across the Alps; others are tanners. A considerable transit trade is carried on between Switzerland and Italy by the St. Bernard, which is the most direct communication between Bern and Turin. The vine thrives on the lower hills, which have a southern aspect, and some of the wines of the Val d'Aosta, especially those of Chambava, Donax, and Carema are not inferior to those of Montferrat; there is some very good muscadel among the rest. In the Val d'Aosta there are all seasons and climates within a short range. On the Alpine summits are perpetual ice and snow; next are forests of firs and larches; lower down, chestnut and walnut-trees; then vines; and, lastly, the olive, almond, fig, and mulberry-trees growing in all the luxuriance of the south. The traveller who descends the St. Bernard finds at once the climate and the sky of Italy, he hears the shrill cicala, and feels a sun as hot as that of Naples.

The river Dora and the other streams afford excellent trout. The duchy of Aosta is rich in iron, copper, and lead ore. There are iron works at St. Vincent, near Châtillon, at Monjovet, at St. Marcel, at Gressan, at Cognà, La Tuile, &c. There is manganese in the Val de Challant, as well as salt-pits, and cobalt and crystal. There is also abundance of mineral springs. Gold-mines are reported to have been worked in the time of the Romans, but all traces of them are now lost: particles of gold, however, are found in the streams, especially in the Evanson, which flows through the valley of Challant, and Saussure says that some of the peasants in his time gathered them in a considerable quantity out of the sand.

The people of these secluded valleys are an honest, quiet, and civil race, who speak a dialect different from the Piedmontese, but resembling rather the romance *patois* of Savoy and western Switzerland. Most of them, however, understand French, and speak it well enough for common purposes; Italian is like a foreign language here, although it is the language of the government, and, as such, spoken by all civil officers and magistrates. The country people retain their old costume; the men wear long frocks of blue, red, or green cloth, short breeches, and worsted stockings of the same colours, buckles to their shoes, and huge cocked-hats. The women wear black or white caps, fastened under the chin, which serve partly to conceal the *goitres*, or wens, with which most of them are more or less afflicted. This is a misfortune which the people of Aosta have, in common with their neighbours of the Lower Valais, north of the St. Bernard: many of them are idiots. This disease is ascribed by some to the water they drink, and by others to the thick, damp

vapours which remain stationary in these deep and narrow valleys. (See *CRETINS*.) A French traveller, Raoul Rochette, states, that while the Val d'Aosta was under the French civil code, and all the children, female as well as male, shared the paternal inheritance, it was observed that Cretinism gradually diminished, the young women consulting their own taste in the choice of their husbands: but under the present Piedmontese law of succession, daughters being deprived of inheritance are induced to contract marriages with Cretins, in order to secure a subsistence, and this is said to have visibly forwarded the spread of goitres. The duchy of Aosta, although small in extent and population, is one of the most interesting provinces of North Italy to the traveller and the naturalist. It lies at the foot of the highest summits in Europe; Mont Blanc, Mont Iseran, the St. Bernard, Mont Combin, Mont Cervin, and Mont Rosa tower above it, and almost inclose it with their glaciers. It is bounded on the north and north-west by the Pennine chain; on the west and south-west, by the Graian Alps; on the south, by a projection from the latter; and on the east, by an offset from the range of Mont Rosa, which separates its easternmost valley, the Val Lesa, from the neighbouring province of Valsesia, in the division of Novara. Over this last range is the pass of Col Valdobbia, above 7000 feet high, affording a communication between the two provinces. A hospice has been lately built on the summit. It is only at the south-eastern extremity of the duchy of Aosta that the mountains leave an outlet into the lowlands of Piedmont, through which the Dora makes its way, and by the side of the river is the only road passable for carriages. The pass is often confined between the mountain on one side and the river on the other. Near Monjovet, King Charles Emmanuel III. had the rock cut out to widen the road. Lower down, between Bard and Donax, the rocks have been cut vertically to the height of thirty feet, and a road twelve feet wide has been thus made with a parapet on the river side, chiselled out of the rock itself: this work is ascribed to the Romans. A column, eight feet high and two in diameter, is sculptured in relief on the side of the mountain, bearing the number XXX. The fort of Bard, now destroyed, rose high above the village of the same name, and completely commanded the pass. The French army under Bonaparte, coming down from the St. Bernard, in May, 1800, was stopped here for several days, by an Austrian garrison of 400 men: the delay might have proved fatal to the conqueror, if the French soldiers had not found means to cut a path over the mountain above, and thus turn the fort; the artillery was hurried through the village in a dark night under a shower of balls from the castle.

The Salassi, a Celtic tribe, are the first inhabitants of these regions mentioned in history: Strabo (book iv.) gives an account of them. They fought repeatedly and bravely against the Romans; they were defeated in the year 718 u. c., by Marcus Valerius Messala, who was obliged to winter among the Alps. The poet Tibullus accompanied Messala in this expedition, to which he alludes in his panegyric of his patron. The Salassi having revolted again, Augustus sent Terentius Varro, who carried on a war of extermination, and completely subdued them; 36,000 of both sexes were sold as slaves at Eporodia (Ivrea). Augustus sent afterwards a colony of 3000 Prætorians, who built the town of Augusta Prætoria, now Aosta. Terentius Varro, having also subdued the Centrones on the other side of the Graian Alps, that country took the name of Tarentasia, which it still retains. Augustus made a carriage road over the mountain, now called the Little St. Bernard, which became the great line of communication from Milan to Vienne on the Rhone. Traces of this road are still to be seen in the Val d'Aosta. After the fall of the empire, the country passed under the dominion of the Goths, the Langobards, and the Burgundians; and lastly, of the Counts of Savoy. Amadeus III., in the thirteenth century, conquered the valley of Aosta, whose inhabitants had insulted and imprisoned his messengers. The Emperor Frederic II., on his passage by Turin, granted Amadeus the title of Duke of Aosta, which was borne in the last century by the second son of the King of Sardinia. The last who had it was Victor Emmanuel, who afterwards became king, and who abdicated in 1821. The duchy of Aosta, being one of the oldest Italian possessions of the House of Savoy, preserved its integrity, its separate administration, and its own laws, and usages. The whole division, province, or duchy,—

for, in this instance, they are all synonymous terms,—contains 73 communes, forming seven *mandamenti*, or districts, under one intendant-general. The population, by the census of 1826, was 64,640 inhabitants. The length of the province from east to west is 55 miles, and its greatest breadth is 30 miles; but the great inequalities of the ground add largely to the extent of its surface, one half of which, however, is occupied by barren mountains and glaciers. (Sausure, *Voyage dans les Alpes*; Millin, *Voyage en Savoie et en Piémont*; Della Chiesa, *Istoria del Piemonte*.)

AOSTA, (la Cité d') the capital of the duchy of the same name, is built on the left, or northern, bank of the Dora Baltea, and at the confluence of the Butier, the water of which is made to flow through the middle of the streets. Most of the houses have gardens and orchards; the streets are wider and more straight than in the generality of old towns; and the extent of the city consequently appears large in proportion to its population, which, by the census of 1826, was only 5500. Aosta is the residence of the *intendente* of the province, and the seat of the courts of justice; it has likewise a bishop's see and a chapter, three parish-churches, besides the cathedral,—a large, old, Gothic structure, in which is the monument of Thomas, Count of Savoy, who died here in 1232. In the eastern part of the town are some arches with pillars and other remains of the antient amphitheatre, the arena of which is now covered with grass and trees. The cellar of a neighbouring convent was formerly the dens of the beasts, and communicated with the arena by subterraneous passages. At the north-west angle of the town is a round tower, which appears to have been intended for a mausoleum. In the city walls, as well as on the outside of several houses, are seen stones and slabs taken from the old Roman buildings. At the entrance of the town, on the road to Ivrea, stands a single triumphal arch of Roman architecture; it is built of a kind of pudding-stone, and the marble with which it was cased having been removed, no inscription or ornament remains, except fragments of the frieze and the lateral pillars. Aosta is pleasantly situated at an opening made by the meeting of several valleys, and in a fertile country. It is nearly 2000 feet above the level of the sea, and is 50 miles N. by W. of Turin and 65 miles S.E. of Geneva, in 45° 45' N. lat., and 7° 16' E. long. Anselm, Archbishop of Canterbury under William Rufus and Henry I., a man of considerable learning for his age, was a native of Aosta. Bernard, of Menthon, in Savoy, the founder of the Hospice of the St. Bernard, was Archdeacon of the cathedral of Aosta.

APANAGE, (*Apanagium*, *Apanamentum*.) the provision of lands or feudal superiorities assigned by the kings of France for the maintenance of their younger sons.

The prince to whom the portion was assigned was called the *apanagist*; and he was regarded by the antient law of that country as the true proprietor of all the seigniories dependent on the apanage, to whom the fealty (*foi*) of all subordinate feudatories within the domain was due, as to the lord of the 'dominant fief.'

Under the first two races of kings, the children of the deceased monarch usually made partition of the kingdom amongst them; but the obvious inconvenience of such a practice occasioned a different arrangement to be adopted under the dynasty of the Capets, and the crown was permitted to descend entire to the eldest son, with no other dismemberment than the severance of certain portions of the dominions for the maintenance of the younger branches of the family. Towards the close of the thirteenth century the rights of the apanagist were still further circumscribed; and at length it became an established rule, which greatly tended to consolidate the royal authority in that kingdom, that, upon the failure of lineal heirs male, the apanage should revert to the crown.

The period at which this species of provision was first introduced into the law of France, the source from which it was borrowed, and the origin and derivation of the term itself, are matters on which the historical antiquaries of France seem not to be agreed. (See Pasquier's *Recherches*, lib. ii. cap. 18. lib. viii. cap. 20; Calvini *Lex Jurid.* 'Apanagium'; Ducange, *Gloss.* 'Apanamentum'; Pothier's *Traité des Fiefs*; and Henault's *Hist. de France*, Anno 1283.)

By a law of 22d November, 1790, it was enacted, that in future no apanage *real* should be granted by the crown, but that the younger branches of the royal family of France should be educated and provided for out of the civil list until they married or attained the age of twenty-five years; and

that then a certain income called *rentes apanagères* was to be granted to them, the amount of which was to be ascertained by the legislature for the time being.

'It is evident, says Mr. Hallam, 'that this usage, as it produced a new class of powerful feudatories, was hostile to the interests and policy of the sovereign, and retarded the subjugation of the antient aristocracy. But an usage coeval with the monarchy was not to be abrogated, and the scarcity of money rendered it impossible to provide for the younger branches of the royal family by any other means.' . . . 'By means of their apanages and through the operation of the Salic law, which made their inheritance of the crown a less remote contingency, the princes of the blood-royal in France were at all times (for the remark is applicable long after Louis XI.) a distinct and formidable class of men, whose influence was always disadvantageous to the reigning monarch, and, in general, to the people.' (*Middle Ages*, vol. i. p. 121, 2d edit.)

A'PATITE, a mineral substance crystallized in the regular six-sided prism, usually terminated by a truncated six-sided pyramid. It occurs variously modified by the removal of its lateral sides and angles. Its specific gravity varies from 3.25 to 3.5. It is scratched by feldspar, but scratches fluor-spar. In colour it passes from white, through various shades of yellow to green and blue, and some specimens possess a red tint; it is usually translucent, but rarely transparent. From the analysis of Gustav. Rose, apatite appears to be a compound of phosphate of lime with fluoride of calcium, in which the fluorine is more or less replaced by its isomorphous element chlorine. Its constitution may be expressed by $3(\dot{C}a + \ddot{P}h) + (Ca + Fl, Cl).$

This mineral principally occurs in the primitive rocks, and is found in the tin veins of St. Michael's Mount, Cornwall, and also in those of Bohemia and Saxony. It has also been observed in a massive mineral called phosphorite, which appears to possess a similar chemical constitution, and has been found abundantly in beds alternating with limestone and quartz, near Logrosan, in Estramadura in Spain.

APLOME. [See GARNET.]

APE, (*Pithecus*.) in zoology, a genus of quadrumanous mammals, which closely approaches to the human species in anatomical structure, and is justly regarded as the connecting link between man and the lower animals. The word ape seems to be of doubtful origin: in German it is *affe*, from which the verb *affen* appears to have come; this is, perhaps, more probable than to suppose that *affe* comes from *affen*. The name exists, with very slight variation, in all the modern languages of Teutonic origin; as *ape* in English, *affe* in German, *aap* in Dutch, &c.; these, also, are the only European languages which possess original appropriate names to distinguish these animals from monkeys in general. Our own language is even more copious than others in terms for distinguishing the different characters of this class of animals: thus we say that an *ape* is a monkey without a tail, and a *baboon* a monkey with a short tail, reserving the term *monkey* more particularly for those species which have very long tails; and though our early writers use these three words indiscriminately as synonyms, and apply them indifferently to the same animal, yet the significations here given have generally prevailed since the time of Ray, and are now exclusively adopted. It must be confessed, however, that these significations are extremely vague, and certainly do not express the zoological relations which subsist between the different sections of this group of animals. Naturalists, therefore, being under the necessity either of inventing new names, or of changing the meaning of the old, have, in the present instance, preferred the latter, and though the change may at first be disagreeable, language and science will be ultimately benefited by its adoption.

According to its modern zoological definition then, the genus *Ape*, or *Pithecus*, comprises those quadrumanous mammals which have the teeth of the same number and form as in man, and which possess neither tails nor cheek pouches. This definition, whilst, on the one hand, it excludes certain tailless baboons and monkeys, comprehends on the other, the three subgenera of orangs, chimpanzees, and gibbons, which, though considered by many good zoologists as generically distinct, yet differ from one another by characters too slight to warrant their separation. Nor are these the only characters which the apes share in common. They, of all other animals, approach most nearly to the human species in organization: indeed, as far as can be

judged from the young subjects usually brought to Europe, their most essential difference in this respect consists in certain modifications of the extremities, which diminish their power of walking with ease on a level surface, but which are admirably adapted to increase their faculty of climbing and grasping. The arms are so long as almost to touch the ground when the animals stand erect on their hind legs; but the legs themselves are scarcely one third of the entire height. The legs, moreover, are not in the same line with the thighs; the knees are turned outwards, and the feet are articulated at the ankle in such a manner that their soles turn inwards so as to face or be opposed to one another. By these means the apes are enabled to embrace or grasp the trunks and branches of trees with much greater force than if their members were constructed like our own: they thus become essentially sylvan or arboreal animals, and never voluntarily abandon the forests, where they find at once the most congenial food and the most perfect security.

Their whole organization peculiarly adapts the apes to these habits. Besides the conformation of the extremities just noticed, the fingers and toes are long, flexible, and deeply separated from one another, and the thumb, or interior finger, is completely opposable to the other four, as well on the posterior as on the anterior extremities; thus, their feet and hands are equally formed for prehension. They are not quadrupeds, as Buffon has justly observed, but quadrumana; not four-footed, but essentially four-handed animals. One part of their organization renders them intermediate between the bats and ordinary mammals; another, makes them the connecting link between man and the inferior animals. The great length of the fingers and anterior extremities, compared with those behind, are precisely what we observe among winged mammals, only that the fingers are not connected by a flying membrane; and their economy and habitat equally correspond with this intermediate structure. They are neither confined to the surface of the earth like the generality of mammals, nor do they possess the power of elevating themselves into the air, like the bats: but they choose a middle habitat, the forests, where they habitually reside, and where they move about with an ease and velocity which can only be compared to actual flight. On the other hand, when compelled by circumstances to traverse any part of the earth's surface, their pace, properly speaking, is neither that of a biped nor of a quadruped: they do not walk upright like a man, nor yet do they walk upon all fours like the lower animals. The great length of their arms prevents them from adopting either of these modes of progression in its simple form, but they avail themselves of this very circumstance in another manner; their long arms serve them instead of crutches, and their pace is precisely that of a lame man who walks with the assistance of these instruments. From the oblique articulation of the posterior extremities, they rest only on the outer edge of the foot, but the wavering equilibrium thus occasioned is secured by the long fore-arms, which can easily touch the ground in all directions; and, when an advance is to be made, it is accomplished by resting the weight of the body upon the half-closed fists, and then swinging the hinder extremities forward, precisely like a man on crutches. In their native forests the extreme length of their fore-arms is turned to the greatest advantage: here it acts upon the principle of the rope dancer's balancing pole, and completely secures their equilibrium even with the most precarious footing. Thus it is that travellers have seen the apes poised at the very extremity of the slender trunks of the bamboo, waving their long arms from side to side, with the most graceful and easy motions.

Another circumstance in the structure of the apes, in which they differ from most other quadrumana, has considerable influence upon their habits; this is the entire want of a tail. Though the presence of this organ does not always indicate a corresponding function, and though its absence is not confined to this group of quadrumanous animals, yet a long tail would seriously embarrass the nearly erect motion of the real apes; whilst its use is in other respects superseded by the length of the fore-arms, which supply its place in adjusting the proper balance of the body, the only function which the tail performs in the common monkeys. But another character of still greater importance distinguishes the real apes from the rest of the quadrumana, viz., the want of cheek-pouches. These are sacks or cavities in the cheeks, which open inside the mouth between the cheek and the lower jaw, and serve to hold

any extra provision which the animal may not at the moment require. The Semnopithecus alone, of all the other monkeys of the old world, resemble the apes in this respect, and hence arise some of the most striking resemblances which the characters and habits of these two genera present. In other respects they are sufficiently distinguished from one another, by the long tails of the Semnopithecus, not to mention their extremities of nearly equal length, and the peculiar structure of their stomachs and teeth. The nature of the influence which the possession of these cheek-pouches exerts upon the characters and economy of animals will be explained under the articles MONKEY, BABOON, &c.; it is here sufficient to observe that they are wanting in the apes. Another character which is common to all the other known quadrumanes of the old continents, is found in some species only of the real apes, and absent in others: this is the possession of callosities, which are naked callous parts of the buttocks, upon which these animals sit, when fatigued by the violent and rapid movements which they habitually execute. Illiger and some other zoologists have considered this circumstance of sufficient importance to warrant the separation of the apes into two distinct genera, the one characterized by the absence, the other by the presence of callosities; but it is to be observed that, even where these organs do exist in the apes, it is always in a rudimentary form; they are never developed to such an extent as to influence the habits of the animals, and are, consequently, unfit to be considered as generic characters. In other respects, except in these diminutive callosities, the gibbons do not differ from the orangs and chimpanzée: they have the same system of dentition, the same organs of sense, and the same singular modification of the locomotive organs; their manner of life also is precisely the same; both equally take up their habitation in the thickest and most solitary forests, inhabit the same countries, and live upon the same food.

The teeth of the apes, as indeed of all the other monkeys of the old world, are of the same number as in man; nor, as far as the incisors and molars are concerned, do they present any difference in form; but in the adult animals, and more especially in the old males, the canines are developed in the same relative proportion as in the carnivora; the tusks of the full-grown orang-outang are at least as large as those of the lion, and are most formidable weapons. Unfortunately we know but little of the manners of these animals in their adult state; but this circumstance gives us strong reason to suppose that the extreme gentleness and placidity observed in the young individuals usually brought into Europe do not always continue to characterize them in their native climates, but that their disposition alters in proportion to the development of their muscular force, and that in their adult state they are as formidable and mischievous as the baboons themselves. In all other respects their anatomical structure so closely resembles that of man, that it is only of late years, and from such trifling discrepancies as the existence or non-existence of a small intermaxillary bone, of a very small perforation in the vertebra of the os sacrum, &c., that anatomists have ascertained that the dissections of Galen were performed not upon the human subject, but upon the magot, or, as it is usually called, the Barbary ape; so perfectly conformable are his descriptions to the structure of the human frame.

The characters and habits of the apes present differences which will be noticed in speaking of the several species. As far, however, as their general manners have been observed, they appear to be of a grave and gentle disposition, totally free from that petulance and mischievous curiosity which so strongly characterize the monkeys, properly so called, very affectionate towards those who treat them kindly, solemn and deliberate in all their actions, extremely circumspect and intelligent, seldom moved to violent passion, but peevish and fretful when crossed or disappointed. They never walk on two legs except when they have occasion to use the fore-hands in carrying something. Nearly, or altogether deprived of callosities, they do not repose in the manner of ordinary monkeys, on their hams, but stretch themselves on their sides, like human beings, and support their heads upon their hands, or by some other means supply the use of a pillow.

A remarkable singularity in the organic structure of certain species of apes has been observed by Sir Stamford Raffles and M. Duvaucelle, to whose researches in the island of Sumatra we are indebted for the greater part of

our knowledge regarding the *gibbons*, or that section of the genus which approaches the lower tribes of monkeys by the possession of rudimentary callosities. It consists in the connexion of the index and middle fingers of the hind hands, which are united as far as the last or nail joint, and are, consequently, incapable of separate or individual motion. The species in which this singularity was first observed has even been named by Sir Stamford Raffles *Simia syndactyla*, from this circumstance; but if the observations of M. Duvaucelle are to be relied on, it would appear, that the conformation is by no means peculiar to this species. It was the opinion of that naturalist, that the females of most, if not of all the gibbons, partake of the same structure, whilst it is supposed to exist in the male of the *Simia syndactyla* alone. Now it must be observed with regard to this opinion, which certainly does not appear to be well-founded, that besides the physical improbability of the males and females of the same species differing in so important a point of their organic structure, a difference of which there is no other known instance throughout the entire class of mammals, M. Duvaucelle's opinion amounts, after all, to a mere conjecture, since he infers the identity of the species to which he attributes this sexual difference, only from the circumstance of having procured his specimens at the same time and in the neighbourhood of one another. The female of the *Simia lar*, also described by the accurate Daubenton, and supposed by MM. Duvaucelle and Frederick Cuvier to be the same as the ounko of the former naturalist, was certainly devoid of this character, expressly assigned to the female ounko, and differed in many other respects, as will appear in the sequel. If, therefore, we admit on the one hand, that M. Duvaucelle's observations establish the existence of this organic singularity in other species besides the *Simia syndactyla*, it appears probable on the other hand, that this gentleman was led into error in attributing it to the females only, from having too hastily considered as sexual differences merely, distinctions which are in reality the characters of different species. This view strips the case of its most serious difficulties; for, as far as the mere union of the fingers is concerned, though it is certainly a remarkable circumstance in the organization of animals so high in the scale of existence as the apes, that modification is by no means peculiar to these animals. The greater number of the marsupial quadrupeds of New Holland, the kangaroos, pottoros, koalas, phalangiers, petaurists, perameles, and phascolomes, possess the same formation, and it is well known that the entire order of insectivores or perching birds are principally distinguished by the same character. In no known instance, however, has it ever been observed to mark a sexual distinction.

1. The *Chimpanzée* (*P. troglodytes*, Linn.) is that species of ape usually placed next to man in the scale of animal existence; though Baron Cuvier has contested its right to occupy this rank in favour of the orang-outang. M. Cuvier's preference of the latter species arises simply from the greater development of the region of the brain, and the comparative height of the forehead, as exhibited in the very young individuals usually brought to this country; but it is to be observed, that these marks of superior mental powers are completely obliterated in the adult animal; and that, in other respects, both the organic structure and intellectual capacity of the chimpanzée appear to be of a higher order than those of the orang-outang. The African species, for instance, has nearly the same proportion between the anterior and posterior extremities that is exhibited in mankind; nor has it the deformed neck and high shoulders of its Indian congener. These circumstances probably produce a greater facility of walking upright, as this species is commonly reported to do, and which is greatly impeded, by the long and disproportionate arms of the orang-outang. But no adult specimens of these animals have ever been brought alive to Europe; they are very seldom met with even in their native forests; and we are not aware that the full grown chimpanzée exists in any museum. Our information is, consequently, derived either from the observation of very young specimens, or from the reports of travellers often detailed at second hand, and, therefore, to be admitted with caution.

The head of the chimpanzée, even in the young individual, is flattened above, with a retiring forehead and a prominent bony ridge or crest over the eyebrows. In this respect it is certainly inferior to the young orang-outang, which exhibits a remarkable elevation of forehead, and a rotundity of the

The Chimpanzée.

cranium much greater than even in the human infant, but its mental capacity does not correspond with these external appearances, and the great development of the face and muzzle degrade it to a close approximation with the lower animals. The face of the chimpanzée, on the contrary, is not relatively more prolonged, in proportion to the capacity of the cranium, than that of the human subject; the proportions of its different parts also more closely assimilate it to the human face, and the mouth, even in the adult animal, appears to want the enormous canine teeth which characterize the Indian species. The mouth itself is wide, the ears remarkably large, the nose flat, and the arms and legs about the same proportion as in man; the fore-fingers quite touching the knees when the animal stands upright. In the orang-outang they nearly touch the ground, in similar circumstances, and the ears of the latter species are remarkable for their very small size and deformed appearance. The body of the chimpanzée is covered with long, coarse, black hair, thickest on the head, shoulders, and back, but thinly furnished on the breast and belly; the face is of a dark brown colour, and, like the ears, naked; the cheeks, however, are furnished with long black whiskers. Finally, the hair on the fore-arms is long and directed towards the elbows, meeting that of the arms which is directed downwards in the usual manner, and forming a small ruff about the joint.

African travellers assure us that the adult chimpanzée attains the ordinary stature of man, and is endowed with a degree of intelligence much superior to other quadrupeds. It inhabits the countries from Sierra Leone to the southern confines of Angola, perhaps even from the Gambia to Cape Negro. Chimpanzée is said to be a name about Sierra Leone, but farther south it is called smitten and pongo, according to Battel and Bosman. Buffon and his copiers have strangely confounded the habits, and even the external form and description of the mandril, a large species of baboon inhabiting the same countries, and called mandril, barris, &c., by the natives with those of the chimpanzée. It is of importance to bear this circumstance in mind, in reading common works of natural history, as nothing is more productive of error than the confusion thus introduced into the history of indige-

species, by forming a purely fictitious being, out of two or more really natural animals. Linnæus upon this, as on all other subjects, judged with greater accuracy than Buffon; yet the great author of the *Systema Naturæ*, with all the profound knowledge, acuteness, and calm unbiassed spirit of inquiry by which he was so eminently distinguished, long hesitated whether to consider the chimpanzée as a second species of the genus *homo*, or the first among the apes. It was only, indeed, in his last edition that Linnæus finally adopted the latter opinion, and learned to consider this extraordinary animal as generically distinct from man himself. That the stories of the pygmies, cynocephali, and other strange and deformed people, supposed by the ancients to inhabit different parts of Africa, arose from vague reports of different species of apes and monkeys, appears to be highly probable; but the term troglodytes, which some authors have supposed to refer to the animal at present under consideration, denoted in reality a race of barbarians, as is well known to those who interest themselves in ancient geography. [See TROGLODYTES.]

All travellers agree in assuring us, that, in a state of nature, the adult chimpanzées live in society in the woods, where they construct huts to protect themselves against the sun and the tropical rains, by intertwining the leaves and branches of trees; that they walk upright, arm themselves with clubs, and unite to defend themselves against the attacks of wild beasts, compelling the elephant himself to abandon the districts in which they reside. It is dangerous for men to enter these forests, unless in companies and well armed; women, in particular, are often said to be carried away by these animals, and one negress is reported to have lived among them for the space of three years, during which time they treated her with uniform kindness, but always prevented any attempt on her part to escape. When the negroes leave a fire in the woods, it is said that the chimpanzées will gather round and warm themselves at the blaze, but they have not sufficient intelligence to keep it alive by fresh supplies of fuel.

The chimpanzées generally brought to Europe, and whose manners have been observed by naturalists, were all of immature age. A specimen exhibited some years ago at the Egyptian Hall, Piccadilly, in company with a young orang-outang of about the same age, afforded a very favourable opportunity for comparing the form and habits of these two animals. The chimpanzée, though in a declining state of health, and rendered peevish and irritable by bodily suffering, exhibited much superior marks of intelligence to his companion; he was active, quick, and observant of everything that passed around him; no new visiter entered the apartment in which he was kept, and no old one left it, without attracting his attention. The orang-outang, on the contrary, exhibited a melancholy and a disregard of passing occurrences almost amounting to apathy; and though in the enjoyment of better health, was evidently much inferior to her companion in quickness and observation. On one occasion, when these animals were dining off potatoes and boiled chicken, and surrounded as usual with a large party of visitors, the orang-outang allowed her plate to be taken away, without exhibiting the least apparent concern: not so, however, the chimpanzée; we took advantage of an opportunity, whilst his head was turned to observe a person coming in, to secrete his plate also: for a few seconds he looked round to see what had become of it, but not finding it, began to pout and fret exactly like a spoiled child, and perceiving a young lady, who happened to be standing near him laughing, or, perhaps, suspecting her to be the delinquent, he flew at her in the greatest rage, and would have probably bitten her had she not got beyond his reach. Upon having his plate restored, he took care to prevent the repetition of the joke by holding it firmly with one hand, while he fed himself with the other.

2. The *Orang-Outang* (*P. Satyrus*, Lin.), the most celebrated of all the apes, is a native of the most remote and unfrequented forests in the interior of Borneo, Java, and Sumatra; perhaps also of the southern provinces of China and the Malayan Peninsula, but the authorities upon which these latter habitats rest, are by no means unquestionable. Though exhibiting in early youth a rotundity of the cranium and a height of forehead altogether peculiar, and accompanied, at the same time, with a gentleness of disposition and gravity of manners which contrast strongly with the petulant and irascible temper of the lower orders of quadrumanous mammals, the orang-outang in its adult state

Orang-Outang.

is even remarkable for the flatness of its retiring forehead, the great development of the superorbital and occipital crests, the prominence of its jaws, the remarkable size of its canine teeth, and the whole form of the skull, which from the globular shape of the human head, as it appears in the young specimen, assumes all the forms and characters belonging to that of a large carnivorous animal. The extraordinary contrasts thus presented in the form of the skull, at different epochs of the same animal's life, were long considered as the characters of distinct species; nor was it till intermediate forms were obtained, exhibiting in some degree the peculiarities of both extremes, that they were finally recognised as distinguishing different periods of growth only.

These characters of the adult animal, as well as the disproportionate length of the arms, the short, thick neck, deformed by two large membranous sacks, which give a peculiarly shrill and hollow tone to the animal's voice, and other details of its general organization, debase the orang-outang in the scale of existence when compared with the chimpanzée. The great length of the arms is certainly the most striking peculiarity about this animal, more particularly when compared with the shortness of the body and legs: when standing perfectly upright, the fingers can almost touch the ground, and hence it arises that the biped station is by no means so convenient for this species as for the chimpanzée. It is seldom, therefore, that the orang-outang attempts to walk on the hind feet alone; but when it does, the hands are invariably employed for the purpose of steadying its tottering equilibrium, touching the ground lightly on each side as it proceeds, and by this means recovering the lost balance of the body. Like the chimpanzée, this species is destitute of callosities; the muzzle is considerably prolonged, the mouth large and ill-formed, the lips thin and protuberant, the chin almost wanting, the ears remarkably small, and the nose so flat as to be recognised only by the nostrils. The face, ears, and hands are naked, and of a reddish brick colour; the fore parts of the body also are but thinly covered with hair; but the head, shoulders, back, and extremities are very thickly clothed with long hair of a dark vinous red colour, directed forwards on the crown of the head, and upwards towards the elbows, on the fore arms. The nails of the hind thumbs are sometimes wanting in young individuals of this

species, but the character is by no means general, much less universal, nor is it a specific distinction, as some writers would have us believe.

The relations which Europeans have maintained with India, ever since the end of the fifteenth century, have afforded frequent opportunities for observing this animal, and many young specimens have been at different times introduced into England, Holland, France, and Portugal. In youth it is principally remarkable for its gentle and affectionate disposition, but the cold and moist character of our northern climates always prevents the development of its faculties, and terminates its life in a very few months. The following account of the habits and manners of a specimen, observed by Dr. Clarke Abel in Java, exhibits the animal in more favourable, because more natural, circumstances. 'Whilst in Java,' says Dr. Abel, 'he lodged in a large tamarind tree near my dwelling, and formed a bed by intertwinning the small branches and covering them with leaves. During the day, he would lie with his head projecting beyond his nest, watching whoever might pass under, and when he saw any one with fruit, would descend to obtain a share of it. He always retired for the night at sun-set, or sooner if he had been well fed; and rose with the sun and visited those from whom he habitually received food. On board ship he commonly slept at the mast-head, after wrapping himself up in a sail. Sometimes I pre-occupied his bed, and teased him by refusing to give it up. On these occasions, he would endeavour to pull the sail from under me, or force me to quit it, and would not rest till I had resigned it. If all the sails happened to be set, he would hunt about for some other covering, and either steal one of the sailors' jackets, or empty a hammock of its blankets. His favourite amusement in Java was in swinging from the branches of trees, or climbing over the roofs of houses; on board, in hanging by the ropes, or romping with the boys of the ship. He would entice them to play by striking them with his hand as they passed, and then bounding from them, but allowing them to overtake him and engage in a mock scuffle. Of some small monkeys on board he took little notice whilst under the observation of the persons of the ship. Once, indeed, he openly attempted to throw a small cage containing three of them overboard; but I had reason to believe that he was not so indifferent to their society when free from observation. On one occasion I observed him, lying on his back, partially covered with a sail, contemplating with great gravity the gambols of a young monkey which was bounding over him: at length, he caught him by the tail and tried to envelope him in his covering. The monkey seemed to dislike the confinement, and broke from him, but again renewed its gambols, and though frequently caught, always escaped. The intercourse, however, did not seem to be that of equals, for the orang-outang never condescended to romp with the monkeys as he did with the boys of the ship. Yet the monkeys had evidently a great predilection for his company, for whenever they broke loose, they took their way to his resting-place.

'But though so gentle when not exceedingly irritated the orang-outang could be excited to violent rage, and on one or two occasions committed an act which, in a rational being, would have been called the threatening of suicide. If repeatedly refused an orange when he attempted to take it, he would shriek violently, and swing furiously about the ropes, then return and endeavour to obtain it; if again refused, he would roll for some time like an angry child upon the deck, uttering the most piercing screams, and then, suddenly starting up, rush furiously over the side of the ship and disappear. On first witnessing this act, we thought that he had thrown himself into the sea; but, on searching, found him concealed under the chains.'

It is very seldom that the adult orang-outang has come under the observation of Europeans. An interesting paper, relative to the capture of an individual seven feet high, likewise from the pen of Dr. Clarke Abel, is contained in the fifteenth volume of the *Asiatic Researches*. This animal was discovered by the company of a merchant ship, at a place called Ramboon, on the north-west coast of Sumatra, on a spot where there were but few trees or much cultivated ground. It was evident that he had come from a distance, for his legs were covered with mud up to the knees, and the natives were unacquainted with him. On the approach of the boat's crew, he came down from the tree in which he was discovered, and made for a clump at some distance, exhibiting, as he moved, the appearance of a tall man-like

figure, covered with shining brown hair, walking erect with a waddling gait, but sometimes accelerating his motion with his hands, and occasionally impelling himself forward by the bough of a tree. His motion on the ground was evidently not his natural mode of progression, for even when assisted by his hands or a stick it was slow and vacillating: it was necessary to see him amongst the trees to estimate his strength and agility. 'On being driven to a small clump,' says Dr. Abel, 'he gained by one spring a very lofty branch, and bounded from one branch to another with the swiftness of a common monkey, his progress being as rapid as that of a swift horse. After receiving five balls, his exertions relaxed, and reclining exhausted against a branch, he vomited a quantity of blood. The ammunition of the hunters being by this time exhausted, they were obliged to fell the tree in order to obtain him, but what was their surprise, to see him, as the tree was falling, effect his retreat to another, with seemingly undiminished vigour! In fact, they were compelled to cut down all the trees before they could force him to combat his enemies on the ground, and when finally overpowered by numbers, and nearly in a dying state, he seized a spear made of a supple wood, which would have withstood the strength of the stoutest man, and broke it like a reed. It was stated by those who aided in his death, that the human-like expression of his countenance, and his piteous manner of placing his hands over his wounds, distressed their feelings so as almost to make them question the nature of the act they were committing. He was seven feet high, with a broad expanded chest, and narrow waist. His chin was fringed with a beard that curled neatly on each side, and formed an ornamental rather than a frightful appendage to his visage. His arms were long even in proportion to his height, but his legs were much shorter. Upon the whole,' adds his biographer, 'he was a wonderful beast to behold, and there was more about him to excite amazement than fear. His hair was smooth and glossy, and his whole appearance showed him to be in the full vigour of youth and strength.'

[The Siamang.]

3. The *Stamang* (*P. syndactylus*, Raffles) is an interesting species of ape discovered in Sumatra by the combined researches of the late Sir Stamford Raffles, and the French naturalists, Diard and Duvaucelle. It is the largest of the subdivision of gibbons, or apes distinguished by the possession of small rudimentary callosities, and in this respect, as well as in its intellectual acquirements, is considerably inferior in the scale of natural beings to the chimpanzee and orang-outang. Its skull is small and depressed; its

face naked and black, a few red hairs only marking the forehead and chin; the eyes deeply sunk under large projecting brows; the nose broad and flat, with wide open nostrils; the mouth opens almost to the articulation of the jaws; the cheeks are sunk under high cheek-bones, and the chin almost rudimentary. The hair over the whole body is extremely thick, long, and of a glossy black colour, much closer on the shoulders, back, and limbs, than on the belly, which, particularly in the females, is nearly naked. The scrotum of the males, also, is furnished with a tuft of very long straight hair, which descends to the knee, and readily distinguishes this sex from the females, which, on the other hand, are easily recognised by their naked breasts and bellies, and prominent mammæ terminated by large nipples. The ears are entirely concealed by the hair of the head; they are naked, and, like all the other naked parts, of a deep black colour. Beneath the chin there is a large bare sack, of a lax and oily appearance, which is distended with air when the animal cries, and in that state resembles an enormous goitre. It is in all respects similar to that already described in the orang-outang, and undoubtedly assists in swelling the volume of the voice, and producing those astounding cries, which, according to M. Duvaucelle's account, may be heard at the distance of several miles.

Nor is this the only point in which these two species resemble one another. The siamang, like the orang-outang, has the hair of the head directed forwards so as to shade the forehead, as in the human species, and that of the fore-arm directed upwards towards the elbow; where, encountering the hair of the humerus, which grows in the contrary direction, it forms a prominent ruff. But the most extraordinary part of the organization of this species, consists in the union of the index and middle fingers of the posterior extremities, from which it derives its specific appellation of *syndactylus*, and which, being connected together as far as the nail-joint, are altogether destitute of separate or individual motion.

The habits and character of the siamang are so vividly painted by M. Duvaucelle, from observations made upon this animal in his native forests of Sumatra, that we cannot do better than translate his account as communicated in a letter to M. F. Cuvier. 'This species,' says M. Duvaucelle, 'is very common in our forests (those, namely, in the neighbourhood of Bencoolen, in Sumatra), and I have had frequent opportunities of observing it as well in its wild state, as in bondage. The siamangs generally assemble in numerous troops, conducted, it is said, by a chief, whom the Malays believe to be invulnerable, probably because he is more agile, powerful, and difficult to attain than the rest. Thus united, they salute the rising and the setting sun with the most terrific cries, which may be heard at the distance of many miles, and which, when near, stun, when they do not frighten: this is the morning call of the mountain Malays, but to the inhabitants of the town, who are unaccustomed to it, it is a most insupportable annoyance. By way of compensation, they keep a profound silence during the day, unless when interrupted in their repose or their sleep. These animals are slow and heavy in their gait; they want confidence when they climb, and agility when they leap, so that they may be easily caught, when they can be surprised. But nature, in depriving them of the means of readily escaping danger, has endowed them with a vigilance which rarely fails them; and if they hear a noise which is unknown to them, even at the distance of a mile, fright seizes them, and they immediately take flight. When surprised on the ground, however, they may be captured without resistance, either overwhelmed with fear, or conscious of their weakness and the impossibility of escaping. At first, indeed, they endeavour to avoid their pursuers by flight, and it is then that their mal-address in this exercise becomes most apparent. Their body, too tall and heavy for their short slender thighs, inclines forward, and availing themselves of their long arms as crutches, they thus advance by jerks, which resemble the hobbling of a lame man, whom fear compels to make an extraordinary effort.

However numerous the troop may be, if one is wounded it is immediately abandoned by the rest, unless indeed it happen to be a young one; then the mother, who either carries it, or follows close behind, stops, falls with it, and uttering the most frightful cries, precipitates herself upon the common enemy with open mouth and arms extended. But it is manifest that these animals are not made for combat; they neither know how to deal nor to shun a blow. Nor is their maternal affection displayed only in moments

of danger: the care which the females bestow upon their offspring is so tender, and even refined, that one would be almost tempted to attribute the sentiment to a rational rather than an instinctive process. It is a curious and interesting spectacle, which a little precaution has sometimes enabled me to witness, to see these females carry their young to the river, wash their faces in spite of their outcries, wipe and dry them, and altogether bestow upon their cleanliness, a time and attention that, in many cases, the children of our own species might well envy. The Malays related a fact to me, which I doubted at first, but which I believe to be in a great measure confirmed by my own subsequent observations: it is, that the young siamangs, whilst yet too weak to go alone, are always carried by individuals of their own sex, by their fathers if they are males, and by their mothers if females. I have also been assured that these animals frequently become the prey of the tiger, from the same species of fascination which serpents are related to exercise over birds, squirrels, and other small animals.

'Servitude, however long, seems to have no effect in modifying the characteristic defects of this ape, his stupidity, his sluggishness, and his awkwardness. It is true, that a few days suffice to make him as gentle and contented, as he was before wild and distrustful; but, constitutionally timid, he never acquires the familiarity of other apes, and even his submission appears to be rather the result of extreme apathy, than of any degree of confidence or affection. He is almost equally insensible to good or bad treatment; gratitude and revenge are sentiments equally strange to him. All his senses are dull and imperfect; if he regards an object, it is manifestly without any intention—if he touches it, it is involuntarily. In a word, the siamang exhibits an absence of all intellectual faculty; and if animals were to be classed according to their mental capacities, he would certainly occupy a very inferior station. Most commonly squatted on his hams, with his long arms twined round him, and his head concealed between his legs, a position which he also occupies whilst sleeping, he is seldom roused from his lethargy, nor does he break silence, unless at intervals to utter a disagreeable cry, which in sound approaches to that of a turkey-cock, but which appears to be expressive of no sentiment, nor to declare any want, and which in reality expresses nothing: hunger itself is insufficient to excite, or divest him of his natural lethargy; he takes his food with indifference, carries it to his mouth without avidity, and sees himself deprived of it without testifying either surprise or resentment.'

4. The *Wouwou* (*P. agilis*, F. Cuv.) has a bluish-black face, slightly tinged with brown in the female: the eyes are approximated, and deeply sunk in the head, owing to the prominent brows which surmount them; there is scarcely any forehead; the nose is not altogether so flat as in the siamang, and the nostrils open by large lateral slits; the chin is provided with a few hairs by way of beard, and the ears are almost concealed by long white whiskers, which, uniting into a narrow band, cross the forehead immediately over the eyebrows. It is difficult to give a precise idea of the colours of this animal, particularly as they are liable to considerable variation on account of age and sex. The fur itself is of a softer and more woolly quality than in the other species: it is of a very dark brown colour on the head, breast, belly, and inner surface of the arms and thighs, becomes insensibly lighter on the neck and shoulders, and finally assumes a blond hue almost white, on the loins and hips. The posterior face of the thighs is a mixture of brown, white, and red; and the backs of the hands and feet are very dark brown, like the belly. The female is not so hairy in front as the male, her eyebrows are less prominent, and her whiskers smaller. The young are of a uniform straw colour. It is likewise to M. Duvaucelle that we are indebted for the knowledge of this species, and for the only account which we possess of its habits and economy. It inhabits the same countries and localities as the siamang, but is less frequently seen, as its surprising agility enables it easily to elude observation or escape pursuit.

'These apes,' says M. Duvaucelle, 'which live more frequently isolated in couples than in families, are the most rare of the genus found in the neighbourhood of Bencoolen. Very different from the siamang in its surprising agility, the wouwou escapes like a bird, and like it can only be shot flying: scarcely has it perceived the appearance of danger when it is already far distant. Climbing rapidly to the tops of the trees, it then seizes the most flexible branches, and

balancing itself two or three times to secure its equipoise, it thus springs successively, without effort as without fatigue, to the distance of forty feet and upwards. As a domestic animal, the wouwou exhibits no extraordinary faculty. It is less clumsy than the siamang, its movements are more prompt and graceful, but its manners are less lively than those of the monkey tribes in general: looking merely upon the exterior of its long slender arms and short bandy legs, one would be far from supposing that its muscles were so vigorous and its address so surprising. Nature, however, has not bestowed upon it a large portion of intelligence; in this particular it is in no way superior to the siamang: both species are equally deprived of that high and expanded forehead, which indicates superior intellectual powers, and this is one of the principal points of coincidence between them. What I have myself seen, however, convinces me that the wouwou is susceptible of a certain education, it has not the imperturbable apathy of the siamang; it may be frightened or pleased; it flies from danger, and is sensible of good treatment; it is gluttonous, curious, familiar, and sometimes even gay. Though deprived of the guttural sack so remarkable in the siamang, its cry is very nearly the same; so that it would appear that this organ does not produce the effect of increasing the sound usually attributed to it, or else, that it must be replaced in the wouwou by some analogous formation.

The height of the adult wouwou, measured from the sole of the foot to the crown of the head, is two feet seven or eight inches; when standing in an upright posture, its fore-arms nearly touch the ground; the thumbs of the hands are very short, but those of the feet are long in proportion, and capable of being completely opposed to the other toes: it has small naked callosities, is entirely destitute of tail and cheek pouches, and in other respects perfectly resembles the common apes of the gibbon family. The female is rather smaller than the male: it is known by different names in Sumatra; that of wouwou is the most common and is meant to imitate the voice of the animal.

5. The *Ounko* (*P. Rafflesii*, Geoff.) is another species discovered, like the siamang and wouwou, during the expedition of Sir Stamford Raffles and MM. Diard and Duvaucelle into the unexplored forests of the interior of Sumatra, and named by M. Geoffroy St. Hilaire, after the first of these distinguished zoologists. This animal, which is called ounko by the Malays of Padang, appears to be of very rare occurrence; since, during fifteen months' residence on the island, the French naturalists above named never had reason to suspect its existence, though they had penetrated the woods in all directions for the express purpose of investigating its zoology. It was only a short time previous to their departure that they made the discovery; and as they enjoyed no opportunity of studying its manners, we are, consequently, deprived of those interesting details which have been furnished regarding the habits and economy of the species last described.

The size of the ounko is a little less than that of the wouwou, to which it bears so close a resemblance in form and proportions, that these two species are only to be distinguished by the difference of their colours. That of the ounko is in general black, less deep and brilliant indeed than that of the siamang, and in some degree resembling the fur of the wouwou in its length and thickness, and in the brown shade which it assumes in certain lights, particularly on the loins, which are a uniform dark brown. It further resembles the latter animal by its large white whiskers, uniting to form a scanty white beard under the chin, and by a narrow band of the same colour across the forehead. The throat is not naked and dilatable as in the siamang, but only more sparingly furnished with short hair than the breast and belly, and the scrotum is provided with a long pendent tuft of hair, tipped with red, and hanging down nearly to the knee. The female, according to M. Duvaucelle, has the index and middle fingers of the posterior extremities united as in the siamang; and upon dissection it was found that this animal had fourteen pairs of ribs, being one more than in the other species. 'Thus,' says M. Duvaucelle, 'the ounko bears a close resemblance to the siamang in the nature and colour of its fur, and to the wouwou in its white eyebrows and whiskers, its physiognomy and general proportions, in the absence of the guttural sack, and in the union of the index and middle-finger on the hind hands of the female only.' This sex further differs from the male by its smaller stature and the absence of the white whiskers, of

which no further trace remains than two light brown marks over the eyes. With this exception the head is uniformly black; the breast and belly have very little hair, but that of the back and shoulders is extremely long and thick, and forms a kind of mane, of which some traces likewise exist, though in a smaller degree, in the siamang and wouwou. The hair of the fore-arm in both sexes, to judge at least from the lithographic plates of M. F. Cuvier, is reversed, as in the siamang and orang-outang; whilst in the wouwou, it is directed towards the wrist as in ordinary mammals.

6. The *gibbon* (*P. lar*, Lin.), originally described by Buffon and Daubenton, and confounded by Sir Stamford Raffles (in his Catalogue of Sumatran Animals, inserted in the 13th volume of the *Transactions of the Linnean Society*) with the ounko, is, however, a very distinct species, and differs not only in its external characters, but likewise in its internal conformation. It is indeed true that these two species resemble one another in the quality and general colour of their hair, and in the white circle which more or less surrounds the face of both, but the hands and feet of the ounko are black, like the rest of the body, whilst in the gibbon they are light-grey, and form a striking contrast with the colour of the other parts; the hair of the fore-arm, likewise, is reversed in the former species, and directed in the usual manner towards the wrist in the latter; at least such is the direction given to it in the engraving of Buffon, and there is nothing said to the contrary either in his description, or in that of the accurate Daubenton, whose notice it could not possibly fail to have attracted, had it existed in his specimen: the index and middle hind toes are separate in the female gibbon, whilst in the ounko they are united (always presuming that M. Duvaucelle's specimens were really the male and female of the same species, of which there is good reason to doubt); and, finally, there are but twelve pairs of ribs in the gibbon, and fourteen in the ounko, as demonstrated by the dissections of Daubenton and Duvaucelle respectively.

The gibbon observed by Buffon was, like the generality of its congeners, of a gentle, affectionate disposition, and quiet and deliberate in all its movements; it was fearful of cold and damp weather, and received the bread, fruit, and other eatables which its visitors presented to it, with a gentleness very different from the abrupt and eager manners of the monkeys and baboons. It was brought from the Indian Archipelago.

7. The *Pithecus leuciscus* of Geoffroy, also called wouwou by the Malays, is a species of which we have at present but an imperfect knowledge. It closely resembles the *P. agilis*, but is of a uniform ashy-grey colour, with a black, naked face; arms still longer than in that species, and much larger callosities. Its hair is of a softer and more furry quality than in the other apes, and its face is surrounded by a circle of light grey, the ears, hands, feet, and top of the head being very dark brown. Professor Camper, who describes this animal, obtained his specimen from the Molucca Islands, where the species is often seen swinging itself among the long slender branches of the bamboo. It is said often to walk upright; its habits are active, and its disposition irritable and passionate.

APPELLEANS. [See HÆRETICS.]

APELLES, one of the most celebrated Greek painters, is generally considered to have been a native of the little island of Cos in the Ægean sea. Nearly all that we know about him, with the exception of some few scattered notices, is contained in the 10th chap. and the 35th book of Pline's *Natural History*. The time of his birth is not fixed, but we are told that he was at the height of his reputation in O. cxii., or about B.C. 332; and as he painted a great many portraits of Philip, the father of Alexander, he could not be a very young man in B.C. 336, the time of Philip's death. He also survived Alexander, who died B.C. 323.

His chief master was Pamphilus, a Macedonian, and a distinguished artist, whose fee was very high. Apelles received instruction from him at Sicyon, a city which for some time before and after this date had a high reputation as a school both of sculpture and painting. Of his earliest essays we know nothing; but we are told that his diligence was unwearied, and that he never passed a day without doing something; 'ut non lineam ducendo exerceret artem.' Winkelmann interprets these words to mean, 'that he never passed a day without trying to improve himself as a draughtsman, a sense which the words will very well bear. The story of his first acquaintance with

Protopogenes the Rhodian painter, as told by Pliny, is creditable to the character of both artists: indeed Apelles is much praised for the frankness and plain-dealing of his character. Another story is told of Apelles as having given rise to the well-known saying, that a shoemaker should not go beyond his last. Apelles placed a picture which he had finished in a public place, and concealed himself behind it in order to hear the criticisms of the passers-by. A shoemaker observed a defect in the shoe, and the painter forthwith corrected it. The cobbler came again the next day, and being somewhat encouraged by the success of his first remark, began to extend his censure to the leg of the figure, when the angry painter thrust out his head from behind the picture and told the shoemaker to keep to his trade.

Apelles excelled in grace and beauty. The painter, who laboured incessantly, as we have seen, to improve his skill in drawing, probably trusted as much to that branch of his art as to his colouring: he only used four colours, as we are told (Pliny). His favourite subject was the representation of Venus, the goddess of love, the female blooming in eternal beauty; and the religious system of the age favoured the taste of the painter. His great picture of Venus, which he had undertaken for the island of Cos, was left unfinished at his death. Another, the Venus Anadyomene, representing the goddess rising from the waves of the sea, was taken to Rome, and placed by the Emperor Augustus in the temple dedicated to Julius Caesar the Dictator. The lower part was injured, and nobody could be found to restore it; but the Emperor Nero, who had a taste for art, finding that the whole picture was going to decay, had it copied by Dorotheus.

Apelles painted many portraits of Alexander the Great, who, we are told, often visited his painting room, and would not sit to any body else. But it is not very easy to reconcile Alexander's rambling life with this account, unless we suppose that Apelles followed him into Asia; a supposition not altogether improbable, if we read the account of the revelries at Susa after Alexander's return from India, and of the number of all kinds of professional artists then assembled to add to the splendour of the festival. (See Athenæus, xii. p. 538; where Chares seems to refer these festivities to the wrong period: and ALEXANDER.) The Macedonian king is even said to have made Apelles a present of Campaspe, a beautiful female, whose graces the painter transferred to his Venus Anadyomene. According to Athenæus (xiii. p. 590, Casaub.), the painter made the beautiful Phryne his model, as she was bathing in the sea at Eleusis.

Apelles painted a portrait of King Antigonus (see his medal), which he placed in profile to hide the defect of the want of one eye. We may form some idea of the state of art in that day by the medal of Antigonus which we have, and by the fame of Apelles which has survived his works; it is not an unlikely hypothesis, that the figure of Antigonus on his coins would be in harmony with his portrait by Apelles.

The great picture of Alexander by Apelles was in the temple of Diana at Ephesus; other pictures by Apelles were in Samos and Rhodes, and Rome contained several in the time of Pliny. A Hercules in the temple of Antonia [see ANTONIA] was attributed to him. Apelles published a work on painting, which unfortunately is lost. He was accustomed to use a varnish for his pictures, which brought out the colours, and preserved them at the same time. The date of his death is unknown.

A story told by Lucian, in his little piece *Περὶ τοῦ μὴ ῥαδίως πιστεῖν διαβολή*, belongs to another Apelles, of Ephesus. (See Pliny; Winkelmann, vol. ii., &c.)

APEL'LICON, a personage principally memorable for his connexion with the preservation of the works of Aristotle. According to Strabo (book xiii., p. 608, &c. Casaub.), he was a native of Teos, but went to Athens, and was admitted a citizen of that state. He was very rich, and his vanity seems to have led him to seek distinction by the assumption of the literary character. He spared no expense in amassing books; but Strabo says that he was rather *φιλόβιβλος* (a lover of books) than *φιλόσοφος* (a lover of wisdom). Among other libraries which he purchased was that which had been collected by Aristotle more than two hundred years before; and which, enriched as it was by the manuscripts of that philosopher himself, and of his pupil Theophrastus, had, according to the improbable story, been long altogether concealed from the world. It had been left, Strabo says, by Aristotle to Theophrastus, and by the latter to his disciple Neleus,

who carried it to his native town Scepsis, in the Troad. On his death it fell into the hands of his heirs; who, not being of a literary turn, and yet aware, probably from the instructions of Neleus, of the great value of the deposit, acted in a manner natural enough in such circumstances. To prevent the books from getting into the hands of the King of Pergamus, in whose dominion they resided, and who possibly might have removed them to the famous library of that capital without much regard to the rights of the owners, they concealed them in a cellar under ground. Here they remained until they were purchased by Apellicon from the descendants of the persons by whom they had been thus secured, about a century and a half afterwards. They had, however, suffered much from their long entombment, and the copyists whom Apellicon employed to transcribe them were not very well qualified to restore the passages which had been rendered illegible. When thus for the first time published, they consequently appeared in a very faulty state. When Sylla conquered Athens (86 B.C.) he carried to Rome, among other literary treasures, the library of Apellicon, who had just died; and this particular collection, Plutarch says, he retained as his own property. Tyrannion, the grammarian, who was a great admirer of Aristotle, contrived to ingratiate himself with Sylla's librarian, and obtained the privilege of using the manuscripts. Several publishers also of that day (*βιβλιοπωλῆαι*) employed bad copyists to make transcripts, and did not take care to have the copies collated with the originals: this, indeed, says Strabo, is a common occurrence in books which are copied for sale, both here (in Rome) and at Alexandria. It was not until Andronicus of Rhodes [see ANDRONICUS], who was an acquaintance of Tyrannion, undertook the task of correcting the writings and putting them in order, that they were given to the world in anything like a correct form. Athenæus (v., p. 214, Casaub.) informs us that Apellicon's passion for rare manuscripts made him very unscrupulous about the means of obtaining them, and that at length he was discovered to have got into his possession the originals of many of the antient public decrees from the city archives, which so enraged the Athenians against him, that he was obliged to run away to save his life. The influence of his friends and his own wealth, however, soon obtained his return; and, having attached himself to the faction of the Peripatetic philosopher Athenion, whom the chances of civil confusion placed for a short time at the head of affairs, he was invested with the command of the island of Delos. In this situation he conducted himself with great incapacity; and the result was, that the Romans effected a descent upon the island, and, falling upon the garrison while they were asleep, put nearly all of them to the sword. Apellicon was fortunate enough to make his escape; and, having returned to Athens, he died there a short time before the capture of the city by Sylla. Athenæus says that Apellicon embraced the opinions of the Peripatetics; and a work of his, in defence of Aristotle, is quoted in a passage of another antient writer preserved by Eusebius. (See Bayle, in articles Andronicus and Tyrannion, and the article ARISTOTLE.)

APENNINES, the general name for the great mountain-system of Italy. The origin and meaning of the name are lost, says Mannert, in the darkness of the early ages. But it is probable that the word contains the element *Pen*, signifying a head or high mountain; this word appears in the same sense in many parts of Europe that were once, or now are, inhabited by tribes of the Celtic family. The Greek historian Polybius speaks of ὁ Ἀπέννινος, and also uses the name in the plural number; Livy and other Latin authors use *Mons Apenninus*, in the singular; the geographer Strabo uses both the singular τὸ Ἀπέννινον ὄρος, and the plural, τὰ Ἀπέννινα ὄρη, from which probably comes the modern plural appellation: but the term *Mons Apenninus*, and ὁ Ἀπέννινος, or τὸ Ἀπέννινον ὄρος, were applied, equally with the modern 'Apennines,' to the whole system of mountains from the Alps to the extremity of Calabria. (See Strabo, pp. 201. 259; Polyb. book ii.)

The great mountain boundary of Italy on the north and north-west terminates on the shores of the Mediterranean with that subdivision of the chain called the Maritime Alps. From Monte Viso, situated near the southern limit of the Cottian Alps, and the most conspicuous feature in that group, rising in a beautiful conical form to the height of 12,586 feet above the level of the sea, the Maritime Alps have a gradual fall to the coast. They also stretch westward nearly to Toulon, where they may be said to have a natural

termination by gradually sinking to a plain; but towards the east they have only an arbitrary line of demarcation, in the neighbourhood of Savona, where the Apennines commence, which may be considered as a prolongation of the great chain of the Alps. The north-western extremity of the Apennines is thus situated near the sources of the river Bormida, north of Finale, a small town on the coast between the Col de San Giacomo, the last of the conspicuous heights of the Maritime Alps, and the Col di Cadibona, the first mountain of the Apennines. From this point (about $44^{\circ} 16'$ N. lat., $8^{\circ} 18'$ E. long.) they stretch in a north-easterly direction until they reach the pass of the Bocchetta, due north of Genoa; thence they continue to run eastward, and a little to the south, to the neighbourhood of Pontremoli, from which point they extend in a general south-east direction, but not without some deviations, through the peninsula, at a nearly equal distance from the coasts of the Adriatic and Mediterranean, to Capo di Leuca, on the eastern side of the Gulf of Taranto. From the centre of Calabria a branch extends nearly due south to Cape Spartivento, ($37^{\circ} 56'$ N. lat., $16^{\circ} 5'$ E. long.) the farthest extremity of Italy: they consequently run through $6^{\circ} 20'$ of latitude. The length of the chain is about 650 English miles in a direct line; but, including its windings, it is little short of 800 miles.

The general outline of the Apennines presents neither the vertical needles of the Alps, the sharp peaks of the Pyrenees, nor the long rocky cliffs or escarpments of the Jura mountains; their forms are smooth, rounded, and wavy, bare rocks scarcely ever appearing, except in the highest parts. The most elevated point is nearly in the centre of the chain, a little eastward of Aquila, where Monte Corno rises to the height of 9521 feet, an elevation, however, which is below the limit of perpetual snow in that climate. The great chain is usually divided into four principal groups, called the Ligurian, Etruscan, Roman, and Neapolitan Apennines.

1. The *Ligurian Apennines* encircle the Gulf of Genoa from the Maritime Alps to Monte Gisa, north of Pontremoli, at the source of the little river Magra, and from thence they stretch in a south-easterly direction as far as the borders of Tuscany. The length of this group is about 120 miles; the crest of the mountain chain is from seven to thirty miles distant from the Mediterranean, and from thirty to fifty miles from the Po. From their north-western extremity the elevation rather diminishes until they reach the pass of the Bocchetta, but from this point there is a gradual rise, and in Monte Pelleggrino, near the south-eastern extremity, they attain an elevation of 5161 feet: the breadth of the group increases with the height, but does not anywhere exceed twenty-five miles. The slope of the mountains toward the sea is abrupt, and is broken by numerous deep gullies, the beds of torrents, which rush down with prodigious violence when swollen by rains. On the Mediterranean side there are only two rivers with a moderate length of course, the Vara and the Magra, which, after uniting their waters, fall into the sea at the entrance of the Gulf of Spezia; but from the northern and eastern slope there are many considerable streams, all tributaries of the Po,—the Bormida, Scrivia, Trebbia, Nura, Taro, Grostollo, and Secchia. The beds of all these rivers are sometimes filled with great torrents, at other times nearly dry, on account of the small quantity of snow which lies upon the mountains from which they are fed. The scenery of the Ligurian Apennines, particularly on the Mediterranean side, is of the most varied and beautiful description; and in the celebrated pass of the Bocchetta, nothing can be more magnificent than the prospect on issuing from the wild mountain ravine, especially to those who there, for the first time, look upon the dark blue waters of the Mediterranean. The mountain barrier between the basin of the Po and the coasts of the Gulf of Genoa is traversed in several directions by great roads, constructed at a vast expense and with much skill. The most considerable of these are, 1. the road from Alessandria up the valley of the Bormida, by Acqui and Spigno, over the pass of Montenotte at an elevation of 4450 feet, to Savona. 2. That from Alessandria over the plain of Marengo, by Novi, Gavi, Voltoggio, and the Bocchetta to Genoa. 3. From Parma by Fornovo, up the valley of the Taro, and over the pass de' Cento Croci to Pontremoli, and thence by the valley of the Magra to Aulla, Sarzana, and the Gulf of Spezia. The communication between the south of France and Italy is by the celebrated road

begun under Napoleon, called the Corniche, which runs along the sea coast from Nice by Oneglia, Savona, Genoa, Chiavari, and Massa, to Leghorn.

2. The *Etruscan Apennines* extend from Monte Pelleggrino to Monte Cornaro, in $12^{\circ} 3'$ E. long., and in a direct line between Florence and Fano, a distance of about 75 miles. In this group the mountain chain approaches nearest to the Adriatic, Monte Cornaro being about twenty-four miles from Rimini, on the Adriatic, and nearly a hundred from Orbitello on the west coast. The slope is rapid towards the Adriatic in the southern part of the group, but in the northern part there is a gradual fall to the marshes of the lower Po and the sandy plains which stretch from thence southward along the coast. On the western side, the mountains throw out numerous branches and fall gradually towards the Mediterranean, sinking southward into the low marshy country of the Maremma. The highest points of the group are, Monte Cimone, 6975 feet, and Monte Amiata, west of Radicofani, 5794 feet above the level of the sea. From the summit of the former, which is a little to the west of a direct line between Modena and Pistoja, there is a most extensive prospect; on one side the vast plain of Lombardy, including the territories of Parma, Reggio, Modena, and part of Romagna, with the Adriatic in the distance; on the other side, a great part of Tuscany, showing the whole course of the Arno to its embouchure in the Mediterranean, which terminates the view. On the eastern side of this group there are numerous streams, but none of great importance; on the western side are the sources of the Tiber, and the Arno which, though much less than the Tiber, becomes a considerable stream by the waters which it receives from these mountains. The communication between Lombardy and Florence is by two great roads over the Apennines, the one from Modena by Pavullo, Pieve-Pelago, on the west side of Monte Cimone, through the pass of Fimalbo, by Pistoja; the other from Bologna by Lojano, through the pass of Pietra Mala, at an elevation of 3284 feet.

3. The *Roman Apennines* run nearly through the centre of the peninsula, from Monte Cornaro to Monte Velino, which is almost due east of Rome, a distance of about 145 miles. In this group are the two most lofty points of the whole chain of the Apennines; they are situated not far from each other, in Abruzzo Ulteriore; the one, called Il Gran Sasso d'Italia, of which the summit, Monte Corno, is 9521 feet above the sea; the other, Monte Velino, is 8183 feet high. Besides these, there are three other mountains of great height; namely, Monte Vettore, 8135 feet, Monte Sibilla, near Ascoli, antiently Mons Tetricus, 7212 feet, and Il Terminillo Grande, north of Rieti, 7034. These are all covered with snow the greater part of the year, for snow falls sometimes in May and September. Between Monte Sibilla and Monte Velino, several branches are thrown off towards the Adriatic on one side, and towards the Mediterranean on the other, the latter having a south-west direction, and one of them accompanying the lower course of the Tiber, as far as the plain near Rome.

4. The *Neapolitan Apennines* include all that part of the mountain system of Italy which extends from Monte Velino to the two extremities of the Terra di Otranto and Calabria, Cape Leuca, and Cape Spartivento, and which no longer forms one great range, but rather a diverging group of subordinate chains. The highest point, towards their northern extremity, is Monte Miletto, in the eastern part of the Terra di Lavoro, the antient Samnium, east of Venafrum, and north of Capua. It is 6744 feet high, and in the valleys of Matese, near its summit, snow is found nearly the whole year. From Monte Chilone, west of Troja, a great branch is thrown off from the central chain, in a north-easterly direction, through the Capitanata, which, turning eastward, runs out to the promontory of Garganum, *Mons Garganus* in Apulia. It rises in several places into considerable elevations, the most conspicuous of which are Monte Calvo, 5295 feet high, and Monte Gargano, which is nearly as much. Another great branch is thrown off not far from Venosa, *Venusia*, and stretches south-east, through the districts of Bari and Otranto, and with a gradually diminishing fall terminates in the low hills between the towns of Gallipoli and Otranto. From the neighbourhood of Venosa the mountains also take a western direction, bending a little to the south, and terminating in Cape Campanella opposite the rocky island of Capri: thus

from Cape Campanella to Cape Leuca the mountains form a continuous curvilinear boundary between the northern parts and the southern portion of this great peninsula. The main chain of the Apennines stretches from the neighbourhood of Venosa to the extremity of Calabria, and rises in many places into mountains of great height. The most lofty of these, Il Pollino, is on the southern limit of the province of Basilicata, (about 40° N. lat.) and is 7076 feet high; patches of snow may be seen upon it even in July. The other lofty mountains of Calabria are, Monte Sivino in Basilicata, 6000 feet; La Sila, east of Cosenza, 4935 feet; and Monte Alto, the highest point of Monte Aspro, east of the straits of Messina, 4380 feet.

Geological Structure.—A kind of conventional boundary has been laid down between the Alps and the Apennines, but it is impossible to draw any line of separation from difference of geological constitution; there is too great a blending and interlacing of formations of different ages, to enable us to say where one system of mountains ends, and the other begins. According to Signor Pareto of Genoa, who has examined the Northern Apennines with more care than any other geologist, there are three great deposits to which the various stratified rocks of Liguria, that are older than the tertiary, may be referred. The lowest is an assemblage of gneiss, mica-slate, clay-slate, talc-slate, and a semi-granular limestone; the next, an assemblage of argillaceous slates, marly sandstones, and slates, sandstones, and limestones; and the uppermost consist of a series of marly limestones, and a sandstone called *macigno*, with impressions of marine plants. These strata, together with some partial deposits of puddingstone, are all more or less inclined, sometimes nearly vertical, and frequently much contorted, particularly the uppermost strata. Upon these are found deposits of tertiary formation, usually in horizontal stratification; but they occur only in detached spots of limited extent, on the Mediterranean side of the chain, while in Piedmont and Lombardy, they form a continuous zone, skirting the northern slope of the Apennines, from Ceva on the west, to Fornovo on the east. The prevailing stratified rock of the Ligurian Apennines, according to Brocchi, is that known in the country by the name of *macigno*; but that term is applied to sandstones of very different ages, and, therefore, some uncertainty attends all descriptions in which it is used. It contains subordinate beds of limestone; but no veins or other deposits of metals have hitherto been found in it. Besides the calcareous beds that are subordinate to the *macigno*, there are extensive tracts of what Brocchi considered, but in some cases at least improperly, a transition limestone in the Ligurian Apennines, and the same rock appears in several places southward, along the shores of the Mediterranean. The mountains of San Giuliano near Pisa are composed of it; the broccatello marble of Sienna is a variety of it, and it is found in insulated hills at Piombino, Civit  Vecchia, and Cape Circello, the antient Circean promontory. Not a trace of this so called transition limestone is to be seen, according to Brocchi, on the eastern side of the Apennines. The southern limit of the *macigno* is not exactly known, but it is supposed not to extend beyond the neighbourhood of Cortona.

Among the unstratified rocks of Liguria, serpentine is by far the most important. According to Pareto, it is not found in the Maritime Alps, but commences near Savona, and occupies a considerable extent of country between that town and Genoa, and as far inland as Voltaggio. It is also met with in many parts of the Ligurian Apennines, forming detached groups of hills many miles distant from each other, and Brocchi describes it as occurring as far as Orbitello, which seems to be its southern limit. It is not confined to the Mediterranean side, but rises up near Bobbio, Fornovo, and between Sassuolo and Modena, in the basin of Lombardy. A variety of serpentine, containing a mixture of felspar and diallage, called in the country *granitone*, and by geologists *gabbro* and diallage-rock, is found in several places; and occasionally of a quality that makes it applicable for works of ornament. Serpentine, under all its forms, is now classed by most geologists among the rocks of igneous origin, and, from the observations of Pareto, Hoffman, De la Beche, and others, it is probable that the great dislocations and contortions which are observed in the stratified rocks of Liguria have been produced by the forcible injection of this rock among them, in a melted state, from the interior of the earth. That the serpentine was in a highly heated condition is inferred from the altered

structure of the slate and limestone, in many places where they are seen in contact with each other. Pareto is of opinion that this eruption of the serpentine took place prior to the deposit of the tertiary beds, but Elie de Beaumont considers that eruptions have repeatedly taken place and even after the formation of the most recent strata, as the tertiary deposits, though usually horizontal, are sometimes highly inclined.

Near the southern extremity of the Ligurian Apennines there is a distinct group, called the Alpi Appuani, separated from the main range by a considerable depression. In this group are situated the celebrated marble quarries of Carrara, which have been worked since the time of Augustus, and continue to supply many kinds for architectural purposes and the finest qualities for sculpture: there is an immense export of the marbles to all parts of the world. This limestone was long considered a primary formation, and was usually referred to as the type of primitive limestone; but it was afterwards thought by many to be of a more modern date, and the German geologist, F. Hoffmann, who has lately visited that part of Italy, has discovered that it contains organic remains, and he assigns it to the same geological age as the oolite or Jura limestones. The highly crystalline state of the rock, and the disappearance of the greater number of the organic remains, he considers to be the effect of heat, when the eruption of the serpentine took place. He traced the limestone uninterruptedly to where it contains numerous fossils; from that point the beds increase in inclination, and gradually change their internal structure, and at last form a mass nearly thirty miles long, scarcely ever at a less elevation than 4000 feet above the sea, and rising often much higher, as in the Panie della Croce, at the southern extremity, 6102 feet, the Pizzo d'Uccello, at the north-west end, 6147 feet, and Monte Sacro, above Carrara, 5540 feet, on the slope of which the numerous quarries are worked. The limestone in the valley of the Frigido lies upon clay-slate, which rests upon mica-slate, and this last upon gneiss, and Mr. Hoffmann is of opinion, after very careful examination, that the two latter rocks are the clay-slate altered and rendered crystalline by the action of heat.

After leaving Liguria, the rock of which the greater part of the Apennines is composed is a limestone which presents itself under different aspects. It contains very few fossils, and affords very little interest to the geologist; its uniformity is absolutely wearisome. Once entered within its domain, we may travel for days without meeting anything to relieve the tedium of its eternal sameness. It is the sole constituent of the Apennines of Tuscany, Romagna, Fabriano, Foligno, and the Abruzzi, and stretches uninterruptedly through the provinces of Basilicata and Bari to the extreme point of Otranto. The Apennines come close to the left bank of the Tiber until that river takes a sudden turn to the south-west, in the immediate neighbourhood of Monte Sant' Oreste, the antient Soracte, which is an outlier of the Apennines, as geologists term such detached hills, when they are composed of the same materials as the main ridge: it rises to the height of 2140 feet. In the Campagna di Roma, a range of mountains, composed of the same limestone, is separated from the central chain by the valley of the Tolero. This detached group, the territory and stronghold of the antient Volsci, extends in a direction nearly north and south, from Monte Fortino, a part of the antient Montes Lepini, to the sea at Terracina, and rises in some places to considerable heights: according to the measurements of Prony, Monte Schiera d'Asino is 4878 and Monte Capreo 4816 feet above the level of the sea. Another subordinate range extends, as has been already stated, between Salerno and Nocera to Cape Campanella, on the south side of the gulf of Naples, of which the island of Capri is a prolongation. In this group, Monte St. Angelo di Castellamare rises to the height of 4688 feet, and Monte Solaro, in the island of Capri, to 3195 feet, according to Tenore in his *G ographie Physique du Royaume de Naples*.

On the western side of the Apennines the limestone is mostly covered by tertiary and volcanic products, so that it seldom appears far from the central chain, unless when the subordinate branches rise to considerable heights. On the eastern side the tertiary deposits do not extend so far south at least they do not cover a great extent of country, and in some places, as in Puglia Pietrosa, a part of antient Apulia, the limestone rises to the surface of the ground, in inclined

beds, from the central range to the sea shore; and in the culture of the olive and vine in that country, they break the masses of limestone to come at a layer of ochreous earth in which to set the plants. From the great scarcity of organic remains, we yet know little with certainty about the geological age of the Apennine limestones, and, indeed, we cannot say if they belong to one or to different periods; it is generally supposed that they belong to some part of our secondary series between the lias and the chalk, and most probably in greater part are equivalents, in point of age, to our oolite deposits. Like most other limestone formations, they abound in great caverns.

Calabria has hitherto been little explored by geologists. The Apennine limestone extends into it; but there are also large tracts of the country occupied by primary strata, and a granitic ridge passes through it, which rises to the height of several thousand feet. There are besides tertiary deposits, to which we shall afterwards allude.

Low hills of rounded undulating forms skirt the northern slopes of the Ligurian Apennines, and cover the greater part of the country on both sides of the Tuscan and Roman Apennines between the mountains and the sea. They have been called by geologists the *Subapennines*, as they never rise above a moderate degree of elevation. They are composed of marls, covered by yellow sand, both abounding in organic remains, and have been considered by Brocchi, who first described them in detail, and by other geologists, as belonging to one period of formation. But Mr. Lyell is of opinion that, while there is a considerable correspondence in the arrangement and mineral composition, there is not that close resemblance in all parts of the Subapennines which should lead us to assume an exact identity of age, and that the fossils they contain indisputably prove that they were deposited during three distinct periods. He considers that the tertiary strata of the hill of the Superga, near Turin, as well as the greater part of those in the valley of the Bormida, belong to the Miocene period; that the greater part of the Subapennine formations of Northern Italy and Tuscany, and perhaps those around Rome also, belong to the older Pliocene period; and that the tuffaceous formations of Naples, the calcareous strata of Otranto, and probably the greater part of the tertiary beds of Calabria, were deposited during the newer Pliocene period. (See Lyell's *Principles of Geology*, vol. iii. ch. xii.)

The marls are composed of clay, with much calcareous matter, are of a greyish-brown or blue colour, often without lines of stratification, but sometimes thinly laminated. They are frequently of great thickness, as in the neighbourhood of Parma, where the marl is 2000 feet thick. They contain beds of lignite and of gypsum, and detached crystals of gypsum; sometimes they pass into compact limestone, and occasionally there are interstratified beds of sandstone. They constitute very frequently the surface of the country, but more usually are covered with sand. The great arenaceous deposit lies generally upon the marl, but sometimes it is seen reposing on the Apennine limestone. It sometimes passes into a calcareous sandstone, and between Florence and Poggibonzi there is a range of conglomerate belonging to the same deposit, extending eleven miles, the pebbles of which are chiefly limestone. (Lyell, *ibid.* vol. iii.) Both the marls and the yellow sand abound in organic remains, but not universally, for there are often large tracts of both without any fossils. The shells are usually in a high state of preservation, even to their colours and the ligament which unites the valves; they are referable to species and families of which the habits are extremely diversified, some living in deep, others in shallow water, some in rivers, others at their mouth. Many are identical with species now inhabiting the adjoining seas, others with species now living in tropical seas. The remains of corals and fishes are not unfrequent, as well as detached bones, and even entire skeletons of whales and other cetacea. The skeleton of a whale twenty-one feet long was found by Cortesi near Castel Arquato, between Parma and Piacenza, in the marl, and oyster-shells were adhering to a part of the head, showing that it must have lain as a skeleton at the bottom of the sea. Bones of land animals are frequently met with, and that they were transported to the bed of the sea is evident from their being associated with marine shells, and from the thigh-bone of an elephant having been disinterred, with oyster-shells attached to it, as in the instance of the whale's skeleton mentioned above.

Besides these marine tertiary deposits, there are others

which are lacustrine, that is to say, the materials must have been deposited in fresh-water lakes. A formation of this sort occurs in the Upper Val d'Arno: this great valley, which is surrounded by precipitous rocks, consists of three distinct basins, connected together; the uppermost is that of Arezzo, the next that of Figline, and the lowest that of l'Incisa. The basin of Arezzo contains a deposit of rolled pebbles, heaped together without any order, with fossil bones in the lower part of the mass, and covering a blue micaceous clay, with bones and beds of lignite. In the basin of Figline, the same clay is covered by rolled pebbles, fine sand, and coarse quartzose sand, and bones have been found in all the beds. In the basin of l'Incisa there are the same deposits of clay and sand, but the pebbles are wanting: these last are larger in size and more numerous in proportion as they are nearer the secondary rocks of Vallombrosa, in the upper part of the valley, from which they have been derived. These deposits rise considerably above the present bed of the Arno; the blue clay, which is always undermost, from 50 to 60 feet; the gravel as much as 200. They contain no fossil marine productions whatsoever, their shells belonging exclusively to fresh water. The most extraordinary circumstance connected with this lacustrine deposit, in the very centre of the Apennines, is the enormous quantity of the bones of great quadrupeds belonging to warm climates, some of them the inhabitants of swamps, and all of extinct species. They are the mastodon, elephant, rhinoceros, and hippopotamus; the skeletons of the latter are exceedingly abundant, no less than forty individuals having been found prior to 1822. Brocchi relates that such is the quantity of elephant bones, that the valley is like a vast cemetery of these gigantic animals, and that before the peasants learned to keep these relics for sale to the curious, they used to inclose their gardens with legs and thigh-bones of elephants. Besides these greater animals, bones have been found of bears, hyenas, an animal like the panther, wolves, boars, tapirs, horses, buffaloes, oxen, and stags. 'In winter,' says Mr. Lyell, 'the superficial degradation of the soil is so rapid, that bones, which the year before were buried, are seen to project from the surface of the soil, and are described by the peasants as growing. In this manner the tips of the horns of stags, or of the tusks of hippopotamuses, often appear on the surface, and thus lead to the discovery of an entire head or skeleton.'

Besides this great lacustrine deposit of the Upper Val d'Arno, there are others of a like nature, such as at Cadibona near Savona, where strata of gravel, sand, and clay are associated with several seams of lignite or brown coal, from two to six feet in thickness, the whole deposit exceeding eight hundred feet in depth. In the midst of the coal beds have been found entire jaws and other bones of an extinct quadruped of the pachydermatous or thick-skinned tribe, called by Cuvier *Anthracotherium*, the bone itself being changed into a kind of coal.

We have still to notice a very important feature connected with the structure of the Apennines, namely, the region which has been devastated by internal fires. This region is nearly confined to the middle part of Italy, and to the western side of it. The volcanic district, properly so called, is bounded on the south by Cape Campanella on the south side of the Bay of Naples, and on the north by the river Ombrone, which enters the sea a little to the south of the island of Elba: the distance between those limits is about 230 miles. Its greatest breadth, which is about forty miles, is at Radicofani in the high road between Sienna and Rome, a volcanic mountain 3060 feet high. Monte Amiata, which is also volcanic, and 5794 feet high, lies immediately west of Radicofani. Volcanic action has long ceased in every part of this district, except at its southern extremity; and there are no historical records of that action, except with respect to Vesuvius and the country immediately contiguous. The volcanic matter which covers the country is mostly in the state of ashes and cinders, either loose or agglutinated together, forming what the Italians call *tufa*; but there have been also eruptions of solid lava in many places, which are now seen in the form of beds and cliffs of hard rock. Of these last one of the most remarkable is the group of hills south of Rome, of which Monte Cavo, the ancient Alban Mount, is the most conspicuous part, rising to the height of 3110 feet. The waters of the Alban Lake fill the crater of an extinct volcano from which streams of lava once flowed over; one of these may be traced by the side of the Appian Way to within two miles of the gates of

Rome. In the quarries there, which have supplied the paving stones of the city both in antient and modern times, the lava is observed to be sixty feet thick, and to rest upon previously ejected cinders. The Lago Bracciano, north of Rome, was once the crater of a volcano, and is now surrounded by hills of solid lava, which send forth numerous branches, antient streams of melted stone, into the surrounding country: and between the lake and Civit  Vecchia there is a chain of limestone hills, at the eastern end of which lava has burst through, and now forms great vertical masses. Another range of hills, composed of compact lava, which branches out on every side, is in the neighbourhood of Viterbo; the highest point, Monte Soriano, the antient Mons Ciminus, is 4183 feet above the sea. The whole surface of the district we are now describing is not covered by volcanic products, for both the Apennine limestone and tertiary formations rise up in many places from beneath them, and in other places they are covered by fresh-water deposits which have been formed since the eruptions ceased. The country round Rome is overspread with volcanic matter, and the seven hills themselves are composed of the same materials lying above marine tertiary formations. These last are laid bare at the foot of the Capitoline Hill; and Monte Mario, on the right bank of the Tiber, 446 feet high, is wholly composed of the Subapennine deposits, large oyster-shells having been found in abundance at the very summit. The volcanic products are found high up among the sinuosities of the Apennine valleys: ascending the bed of the Teverone, stony tufa forms lofty rocks near Vicovaro, above Tivoli, and still farther, at a short distance from Subiaco: in the valley of the Tiber it surrounds the insulated Soracte, and it is also found in the valleys of that branch of the Apennines which terminates in the sea at Terracina. It is an important circumstance in the geological history of Italy that the volcanic products alternate in many situations with the tertiary marine deposits, and that elephants' bones have been found at considerable depths imbedded in the tufa. Marine shells are contained in the tufa or volcanic ashes on the summit of Monte Cavo, at an elevation of more than 3000 feet above the sea. We pass over, at present, Mount Vesuvius and the great volcanic district which surrounds it, because these will be treated of with more detail upon a future occasion. There are several instances of volcanic action more in the centre of the Apennines, and far detached from the great region of volcanos we have been speaking of, as at Teleso, between Capua and Benevento, and Mount Vultur in Apulia.

We have alluded to deposits still newer than the volcanic ejections; these are of fresh-water formation, and are an important feature in the physical structure of the country. They are composed of sands, clays, and marls, and of the solid stone called travertino, a corruption of the antient name for it, viz. *Tiburinum*, because it was found in great abundance near the town of Tibur. All these deposits contain lacustrine shells, particularly such as frequent stagnant waters. The travertino is a deposit from water holding carbonate of lime in solution, by means of the carbonic acid which is common in spring waters; by exposure to air the carbonic acid escapes, and the carbonate of lime is deposited: such springs abound in many parts of central Italy within the volcanic region. In some parts of Tuscany the slanting sides of hills are covered with travertino. Several instances are mentioned by Mr. Lyell (*Principles of Geology*, vol. i. ch. xii.), and many by Brocchi, in his work on the geology of the neighbourhood of Rome. At Vignone, near Radicofani, a spring has deposited a series of strata to the depth of 200 feet, and the stone is so compact as to form an excellent material for architectural purposes. At San Filippo, the water is so highly charged with calcareous matter, that a hard stratum of stone, a foot in thickness, is obtained in four months, and there is a deposit of it a mile and a quarter in length, a third of a mile in breadth, and 250 feet thick in some places. There are vast formations of travertino at Tivoli, and quarries of it at Ponte Leucano in the neighbourhood, which have supplied the materials for some of the most splendid edifices of antient and modern Rome. These fresh-water deposits appear in so many places, that there is every reason to believe they extend over the whole country around Rome. Travertino, containing fresh-water and land shells, some of which are identical with the snails now common in the gardens of Rome, forms thick solid beds on the Aventine Hill above half a mile in length; and fresh-water deposits are found at the height of 150 feet above the

Tiber on the Esquiline Hill. In many places they contain the bones of elephants, and other land animals, as in the celebrated *Mons Sacer* near Rome, where elephants' bones, incrustated with calcareous spar, were dug out of a gravel pit, at a depth of thirty feet below the surface.

Before concluding this rapid sketch of the geological structure of the Apennines, it will be useful to draw the attention of the reader to those great revolutions in the physical constitution of Italy, which the records preserved in her mountains and her soil so clearly point out. Many and great changes must have taken place in that portion of the crust of the globe long before the Apennines were formed. upon the consideration of these we shall not enter, but shall confine ourselves to events of a more recent geological date. It is an established principle in geology, that all stratified rocks containing marine remains must have been originally deposited at the bottom of the sea in a horizontal, or nearly horizontal position, and the inclined strata of the Apennines must therefore have been upheaved from the bed of the ocean; it is probable that they were at the same time raised some thousand feet above the surface of the water, forming a long tongue of land, or a chain of islands. The rocks of which they are composed must have been afterwards in part broken and abraded, to supply the materials of the conglomerates and other tertiary formations now found at their foot, for in all these the parent rock is recognizable, in rounded pebbles. These materials must have been washed down into the adjoining seas, together with remains of plants and of the animals which inhabited the land, where they formed stratified deposits, inclosing, during the process of consolidation, shells and other marine bodies. By a renewal of the internal elevating force these deposits were in their turn upheaved to form the Subapennine hills, and at the same time the central mountain chain must have been raised to a greater height, greater extension must have been given to the land, the islands disappearing as the lower parts of the mountains, of which they formed the summits, rose more and more above the surface of the water; and thus must Italy have assumed nearly its present form. But during the time that those tertiary formations were in progress, there must have been submarine volcanos at work, which, from time to time, spread their ejections over the bed of the sea, and thus they became interstratified with the materials pouring down from the land. There must then have ensued a renewal of the upheaving force, and the effect of that, whether by sudden or by continued gradual elevations during a long period, amounted to a raising of the land at least 3000 feet, for marine shells are imbedded in the volcanic tufa of the Alban Mount at that height above the present level of the Mediterranean. This elevating process must have taken place subsequently to the ejection from the submarine volcanos of the ashes and tufa which cover the country more or less on the western side of the Apennines from Tuscany to the borders of Calabria; for they are, for the most part, arranged in regular stratified beds and contain marine shells. That they were not deposited in fresh water is also evident from this, that they are found in the islands of Ischia and Procida where no great lakes could have existed; and in the former, marine shells imbedded in tufa were observed by Mr. Lyell at an elevation of 2600 feet. The new land thus laid bare must, in process of time, have become covered with vegetation, flourishing in a climate suited to the rhinoceros, elephant, and hippopotamus, which, with numerous other animals belonging to species now extinct, and of kinds now unknown in Italy, must have roamed there in vast numbers. In this state of things, parts of the country must have been covered by vast lakes of fresh water, for lacustrine deposits are met with at intervals nearly over the whole peninsula. Subsequently to this epoch, other great revolutions must have taken place when the barriers of these lakes were broken down, and when the erosions of torrents and denudations of floods fashioned the surface of the country into those forms which it now presents. Such are the conclusions to which an examination of the geological phenomena of Italy seems to lead.

The Flora of the Apennines is so very nearly the same as that of the Alps, that it would be superfluous to add anything respecting their botany, beyond referring to the latter article.

APENRADE, a Danish sea-port, situated at the bottom of a gulf, called the 'Apenrader F rde,' in the Little Belt, about twenty-seven miles N.N.W. of Schleswig, in the duchy

of which name it is comprised. It has sea-baths, a townsmen's and charity school, cotton-print works, and three poor-houses, and is defended by a castle, in which the bailiff of the place resides. The trade and navigation of the town support a population of about 3000. The harbour is shallow, and the shipping, therefore, are moored about a hundred yards below the bridge. Its open roadstead is unsafe in winter time. Long. $9^{\circ} 38'$ E., lat. $55^{\circ} 8'$ N.

APEREA, a species of wild guinea-pig. [See CAVY.]

APERIENTS, in medicine. [See CATHARTICS.]

APETALOUS plants constitute one of the divisions in Jussieu's *Natural System*. They comprehend all genera which are dicotyledonous or exogenous, and which have a calyx without corolla; by some they are called monochlamydeous. The character by which these plants are defined is as constant as any of those which botanists employ for subordinate divisions, but it must not be considered absolute: for not only are many of the genera which, in consequence of their natural affinities, are included among apetalous plants provided with rudimentary petals, but it occasionally happens that in orders otherwise constantly furnished with a corolla, particular genera occur in which no petals are produced; a very remarkable instance of which is to be met with in the pretty little shore-plant found on most of the sandy beaches of this country, and called *Glaux maritima*. This species is very nearly related to the primrose, and certainly belongs to the same natural order as that plant, but it has no corolla; in place of which the border of the calyx becomes coloured, and it therefore apparently belongs to the apetalous division, although, in reality, it forms an exception to the character of monopetalous plants. It is circumstances of this kind that chiefly constitute the difficulty of studying plants according to the *Natural System*; but it is a very great mistake to suppose that such cases are numerous enough to prove a serious obstacle to the student.

APHELION, from the Greek ἀπὸ, *from*, and ἥλιος, *the sun*, means that point of a planet's orbit which is farthest from the sun. Its opposite point is the PERHELION, from περί, *near to*, and ἥλιος, *the sun*, which is the nearest point to the sun.

Let S represent the sun, S A B the earth's orbit, or plane of the ecliptic, and S A a parallel to the line in which the earth's equator cuts the ecliptic, from which line all heliocentric longitudes (that is, measured round the sun) are measured in the direction of the earth's motion, represented by the arrow. Let C D E be a part of the orbit of a planet, S E the longest line which can be drawn through S, then E is the aphelion of the planet. If a plane S E G be drawn perpendicular to the ecliptic, the angle A S G is the heliocentric longitude of the aphelion E. The term is not usually applied to satellites, though they too have their aphelia.

The supposition of the planets moving in elliptic orbits round the sun is not true, unless the ellipses themselves be supposed slowly to change their positions and figures. In all the planets, except Venus, a very little more than a complete revolution must be made between two aphelia; in Venus, on the contrary, a little less. This inequality is represented by saying, that the aphelia of all the planets, except Venus, slowly increase in longitude, while that of Venus decreases. The apparent motion of the aphelia is greater than the real, since the line S A moves slowly backwards. [See PRECESSION.] The apparent annual motion of the aphelia is the annual precession of the equinoxes, together with the real annual motion, except in the case of Venus, in which the apparent motion is the precession of the equinoxes *diminished* by the real motion. The apparent motion of the aphelion of Venus is like that of all the others, in the direction of the earth's motion, for though the aphelion of Venus moves backwards, the line S A does the same at a greater rate. The following table gives the heliocentric longitudes of the aphelia of the bodies of the solar system at the dates specified, together with the *apparent* annual increase of longitude, made up of real increase and precession, as above described. Those of the

new planets and comets cannot yet be considered as ascertained with the same degree of accuracy as those of the old planets. All but the comets are taken from *Baily's Astronomical Tables and Formulae*.

Old Planets, January 1, 1801—

Planet.	Helioc. Long. of Aphelion.			Yearly apparent Increase of Da.
Mercury	254°	21'	47"	55"·9
Venus	308	43	53	47·4
Earth	279	30	5	61·8
Mars	152	23	57	65·9
Jupiter	191	8	35	57·1
Saturn	269	9	30	69·1
Herschel	347	31	16	52·5

New Planets, January 1, 1820—

Vesta	69°	33'	24"	94"·2
Juno	233	33	46	undetermined.
Ceres	327	7	32	121·3
Pallas	301	7	4	undetermined.

Comets—

Date.	Name of Discoverer.	Long. of Aphelion.
1835	Halley	123°
1832	Encke	337
1832	Biela	288

The longitude of the aphelion of Halley's comet is that predicted for its approaching appearance.

APHIS, the plant-louse, or puceron, an extensive genus of insects, interesting to naturalists on account of their very peculiar economy, and no less so to gardeners and farmers on whose crops many species commit most destructive depredations. As instances of the latter we may refer to the hop-fly (*A. humuli*) and the bean-dolphin (*A. fabæ*): flowers, such as the rose, the China aster, and the various chrysanthemums, suffer from other species. During the summer of 1833, the cabbage and turnip crops in Kent were much injured and often destroyed by countless swarms of *A. brassicae*.

These insects are characterized by a soft oval body, a small head, entire and semi-globular eyes, antennæ of seven joints longer than the body, often setaceous, sometimes thickened towards the top, the two joints at the base very short, the next very long and cylindrical. The beak (*haus tellum*) arises from the under part of the head between the fore-legs, and descends almost perpendicularly. The wings, when developed, are four in number, but some naturalists represent the upper wings rather as wing cases (*elytra*) from their difference of texture. The legs are very long and slender, in consequence of which they walk awkwardly. In sketching the history of these singular insects, it will be most convenient to begin it at the close of autumn, when many of the species, such as *A. quercus*, *A. rosæ*, &c., are numerous, some winged and some without wings, of both sexes, so that while the first may fly to a distance, the second are confined to their native plant or its vicinity.

After pairing, the mother aphid deposits what have been, by some naturalists, termed eggs, in a place suitable for their passing the winter; but different places are chosen by different species; some choose the oak, and place the eggs on an exposed twig high on the tree, others in the sheltered crevices of bark, or even under ground. Bonnet seems to be of opinion that the aphides are always viviparous and never lay eggs, what are commonly called eggs produced in autumn being a sort of cocoon, consisting of the young aphid inclosed in an envelope. From our own observations on those of the oak, we are convinced that this is the fact; but we cannot affirm, upon negative evidence, that none of the species lay real eggs.

The cocoons or eggs, whichever they may be, remain torpid during the winter (the parents having died after producing them,) and are called into life with the return of genial weather in the spring. The number of insects produced must of course correspond to the number of cocoons or eggs laid the preceding autumn, but being all ushered into active life at the same time, their simultaneous appearance has led to the popular, but erroneous notion, that they are generated by the air. *Blighting* weather, as it is termed, is also accused of spreading the destructive swarms over hop-grounds or bean-fields, but their rapid increase is wholly caused by their wonderful powers of multiplying.

All the aphides, it has been well ascertained, which appear in spring are exclusively females, no males being found till the autumn; and these females are endowed with a

fecundity almost incredible. M. Latreille says, one female during the summer months will produce about twenty-five a-day, and M. Réaumur calculated that one aphid may be the progenitor, during its life, of the enormous number of 5,904,900,000 descendants. It is not necessary for the young female aphides produced during summer to pair with a male, which indeed would be impossible, as no males are then to be found; yet these females go on producing each their twenty-five a-day of living young ones, all of which become in a short time as fertile as their parent.

This is a circumstance so different from anything known amongst other animals, and altogether so extraordinary, that it could not be credited had it not been proved beyond all contradiction by the careful experiments, suggested by Réaumur, of the French academicians, which may be seen at length in *Insect Miscellanies*, chap. x. The result was, that nine generations were obtained without pairing in the course of three months.

At the extremity of the abdomen most species are furnished with a pair of projecting tubes, through which they eject a sweet viscid fluid, well known under the name of *honey-dew*, erroneously supposed to be an exudation from the leaves on which it is found. It is also said that the aphides feed on this, which is impossible from the structure of their mouths. Ants, however, and bees, are very fond of it.

A'PHORISM (*ἀφορισμός*), literally 'a limitation,' or 'a fixing of limits,' and hence used by the Greek writers to express a short sentence, containing a moral precept, or a rule of practice, briefly and forcibly expressed. The term has been adopted in medicine; for instance, both Hippocrates and Boerhaave have written books entitled *Aphorisms*, containing medical maxims, not treated argumentatively, but laid down as certain truths. For example, 'Neither repletion nor hunger, nor anything which exceeds natural limits, is good.' The word is similarly used in the civil law. We give the following as specimens of moral aphorisms.

'It is always safe to learn from our enemies; seldom safe to instruct, even our friends.'—*Lucon*. 'He will easily discern how little of truth there is in the multitude; and though they are sometimes flattered with that *aphorism*, will hardly believe the voice of the people to be the voice of God.'—*Brown's Vulgar Errors*, book i. 3.

Sayings of this description are well adapted to make an impression on the memory; but they tend to substitute authority instead of judgment, as the motive of action, and may therefore be as well applied to maintain prejudices as to assert truths; to impose conventional and needless restraints, and to furnish safe rules of conduct to the inexperienced. It is with reference to this that Milton uses the word. 'There is no art that hath been more cankered in her principles, more soiled and slubbered with *aphorisming* pedantry, than the art of policy.'

APHRODITE, the goddess of love and beauty. According to Homer, she was the daughter of Zeus and Dione, one of the Nereides, or ocean nymphs: a later legend, told by Hesiod (*Theog.* 188), relates that she sprung from the foam of the sea, produced when Kronos threw into it the reputed members of his father Uranos. There was a celebrated picture of her rising from the sea (*ἀναδυμένη*), deemed the master-piece of Apelles. (See *APKLES*.) She first came to land at the island of Cythera, and thence proceeded to Cyprus. These islands were her favourite places of resort, and many of her epithets are derived from them (Cytherea, Cypria, Paphia, &c.). She was assigned to marriage to Hephæstus (Vulcan) the god of metal-work, and there is a well-known tale of her detection in her amour with Ares (Mars) (See *Odys.* viii. 266). Hermes and Poseidon (Mercury and Neptune) were also among her favoured suitors. Her amours, however, were not confined to the gods. For her adventures with Adonis, see that title: she also bore Æneas to Anchises, a youth of the blood royal of Troy, as is largely related in the Hymn to Aphrodite, ascribed to Homer. In the Trojan war she was engaged with Apollo and Ares on the side of the Trojans, and attempting to protect her son Æneas, was wounded by him. According to the fictions of the *Æneid*, she continued to extend her maternal care over Æneas, and brought out his establishment in Italy, and through him the Italian family derived their descent from her. To the Italians she is known by the name of Venus; a goddess, probably, of indigenous origin, but so confounded in the

fictions of poets and mythologers with the Greek Aphrodite, that her original attributes have nearly disappeared.

The goddess is usually represented naked, or with very scanty drapery: her peculiar attribute is the *cestus* (*κιστός*, *ἰμάς*, *Il.* xiv. 214), or embroidered girdle, which had the power of inspiring love for the person who wore it. Her favourite animals were the swan, the sparrow, and the dove; her favourite plants, the rose and myrtle. The bird called iunx, much used in amatory magic, was also sacred to her. It is a general opinion that her worship was introduced from Phœnicia, and that she is identical with Astarte, the Phœnician goddess of the moon. In the antient temples of Cyprus she was adored under the form of a conical stone, which was probably an *ærolite*. The Grecian artists represented her as the perfection of female beauty. One picture of Apelles we have mentioned; another, which he left imperfect, was esteemed so much that no artist dared to complete it. Many representations of the goddess in sculpture, on coins, &c., are extant: among these, the celebrated statue, called the Venus de' Medici, is that with which we are most familiarized.

APHTHONIUS, a Greek rhetorician of Antioch, whose epoch seems rather difficult to fix; some place him about the end of the second century A.D.; others, as Fabricius, in the third, and other critics still later. We know with certainty that he lived after Hermogenes, because he quotes this rhetorician, and, in fact, worked up the *Progymnasmata* of Hermogenes into a new shape, also entitled *Progymnasmata*. There is a curious passage in *Aphthonius* about Alexandria. (See De Sacy's *Abd-Allatif*, p. 182.) Aphthonius has also left forty Greek fables.

The work of Aphthonius is an elementary treatise on rhetoric; and in the sixteenth and seventeenth centuries it was much in use, and there were numerous editions of it. Since the end of the seventeenth century, Aphthonius has had no editor, and we believe very few readers.

Aphthonius was first printed by the elder Aldus with the other rhetoricians: *Rhetores Græci*. Venice, 1508, fol. The latest edition is by J. Scheffer, Upsal, 1670 and 1680, 8vo., with the *Progymnasmata* of Theon.

APIAN, or **APPIAN** (PETER), an astronomer, and, we may add, astrologer, born at Leipzig, died at Ingoldstadt, where he was professor of mathematics, in 1552, aged fifty-seven. His real name was Bienewitz, sometimes misspelt Binewilt. *Biene* in German signifies a *bee*, whence the Latin *Apianus*. He was in favour with Charles V., who gave him an order of knighthood and the title of Count, as well as more substantial rewards. He is principally remarkable for his observations of comets, and is said to have been the first who observed that their tails are generally turned from the sun. He also attempted the solution of astronomical problems by mechanism, as described in his *Opus Casareum*, and is said moreover to have pointed out the use which might be made of lunar observations in navigation. For a list of his works (which are now uninteresting), see Vossius's *de Scientiis Mathematicis*; Montucla, *Histoire des Mathém.*, vol. i. p. 623; and Hutton's *Mathematical Dictionary*, article 'Apian'; but more particularly Kästner, *Geschichte der Mathematik*, vol. ii. p. 548, where more detail is given; or Teissier, *Eloges des Hommes Savans*, Leyden, 1715. His son Philip succeeded him at Ingoldstadt, which place he was obliged to quit in 1658, on account of his embracing the Protestant religion. He enjoyed some celebrity as an astronomer and mathematician, and died professor at Tübingen, in 1589. It is not correct, as stated in several accounts of which Montucla is apparently the source, that the only work of his which has been preserved is a letter to the Landgrave of Hesse Cassel. (See *Biographie Universelle*, and the work of Teissier above cited.)

APIARY, a place for keeping bee-hives, derived from the Latin *apis*, a bee, and formed like the word 'aviary.' The proper situation of an apiary engaged the attention of antient bee-keepers as much as it does in modern times, and, leaving out a few fanciful particulars, the directions given by Columella and Virgil are as good now as when they were written.

As to the aspect of the apiary, Virgil says—

'A station must be found
To gusts of wind impervious.'—*Georgic* iv.

Milton alleges that 'it is not material in what aspect the stock stands, provided the sun shines on the hive once in the course of the day, for that well-peopled hives, kept dry, will thrive in most situations.' Wildman, again, tells

us, that the apiary should face between the south and west, in a place neither too hot nor too much exposed to the cold. 'I have ever found it best,' he says, 'to place the mouth of the hives to the west in spring, care being taken that they enjoy the afternoon sun; the morning sun is extremely dangerous during the colder months, when its glare often tempts these industrious insects out to their ruin; whereas the mouth of the hive being then in the shade, the bees remain at home, and as clouds generally obscure the afternoon's sun at that season, the bees escape the temptation of going out. When food is to be obtained, the warmth of the air round the hive continues in the afternoon, which strengthens the bees, and enables them to pursue their labours.' Dr. Evans, in his pretty poem, gives very similar directions—

'Screen'd from the east, where no delusive dawn
Chills, while it tempts them o'er the dew-damp lawn;
But as on loaded wing the labourers roam,
Sol's last bright glories light them to their home.'—*The Bees.*

Bonner stands alone in recommending an easterly aspect, which we frequently observed to be chosen in the numerous apiaries in Germany; we found those in Switzerland and Savoy more commonly placed towards the west.

Wildman prefers a situation in which bees 'returning home from their labours may descend,' and Keys says, 'a valley is preferable to high grounds to favour their increase;' but this is of less importance, perhaps, than having free egress and ingress in right lines from and to the apiary.

As to the adjuncts of the apiary, the old recommendations of Virgil are as excellent as any in modern works. He says—

'Let fresh springs and ponds,
Verdant with moss, be near; and shallow brooks,
That with swift current through the meadows run;
The neighb'ring banks may tempt them to avoid
The heat; and trees with hospitable boughs
Obvious detain them. Whether dull in ponds
The water stand, or flow in living rills;
Into the midst throw willow-boughs across,
And planky stones; where, as on bridges rais'd,
They may alight; and to the summer-sun
Expand their wings; if chance the eastern blast,
Beleag'ring, has sprinkled them returning late;
Or plung'd them, blown askance, into the waves.'—*Trapp.*

Dr. Bevan thinks an apiary would not be well situated near a great river, nor in the neighbourhood of the sea, as windy weather might whirl the bees into the water and destroy them; yet we have seen very thriving apiaries all along the Rhine, and on the borders of the Swiss lakes. Others have recommended the neighbourhood of the seacoast as very eligible, from a notion that the bees are fond of sea water, which, however, Keys denies from personal observation, his own bees having been kept near the sea.

Heaths, or places abounding in wild flowers, are the best sites for an apiary, and, in default of this, pasturage must be provided, such as gardens where flowers are cultivated, and fields in which are sown buck-wheat, clover, or sainfoin. The expedient of transporting apiaries to distant places, so as to take advantage of the seasons when different flowers are in blow, has been resorted to in various countries, particularly in Egypt, and along the great rivers of Europe.
